which deals with finance and supplies, should be an exhaustive chronicle of the means and measures adopted for dealing with a unique situation. While this book might at first be dismissed as merely a dull weighty tome, it is far from being so. Much that is interesting emerges during even a cursory perusal of its pages. As the British Army profited by its experience in the South African war, so the United States War Department benefited greatly by the lessons learned on the Mexican Border in 1916. It is obvious that during the first years of the great war the American Army Medical Department was most carefully watching the development of events in Western Europe, and had not been blind to the difficulties and experiments of the various warring nations. Furthermore, the department realized the magnitude of its task and "started big." In spite of this, the original estimates had to be revised from time to time, and the close of the war found the department with large contracts which had to be cancelled. Simplicity and standardization best describe the means employed to keep the army supplied with medical necessities. The great distance from the seat of war and the shortage of shipping were outstanding difficulties. Motor ambulances and other vehicles and appliances had to be taken apart and boxed to fit them into the small space allotted on board ship. As the equipment of a thousand-bedded hospital occupied 39,000 cubic feet of space and weighed 120 tons, it is easy to realize the difficulties of assembling, packing, storing, and shipping all this material overseas. While the book will be mainly consulted for reference purposes it may at the same time be read with interest. It contains a wealth of detail and is obviously written with a scrupulous regard for accuracy. Inspired as it is with the authority and considered opinions of an official department, it is a mine of valuable information, which not only serves as an important historical record of the past, but will be a useful guide to medical departments in the future.

NOTES ON BOOKS.

UNDER the title of *The Physiology of Oral Hygiene and Recent Research*,[1] Dr. SIM WALLACE brought together a number of papers and lectures expressing his views on the functions of the saliva and the causation and prevention of dental diseases, and a new edition has now appeared. In the author's view the function of saliva is to promote oral hygiene and dental diseases are all of local origin—lack of oral cleanliness. As our readers must be well aware by now, Dr. Wallace finds little of value in the work of Mrs. Mellanby. Unfortunately, a series of collected papers tends to prolixity, and here there is no exception. But that does not do away with the fact that *Oral Hygiene* is a contribution to "the other side of the question."

Professor A. GROTJAHN'S fascinating work on *Doctors as Patients*[2] contains as its subtitle indicates, the descriptions of doctors' illnesses described by themselves. The book is divided into three parts. The first which consists of extracts from medical autobiographies, includes accounts of acute infectious diseases, nervous and mental disorders, surgical affections, senescence, and the approach of death, by such well-known writers as Cardan, Trendelenburg, Ebstein, Naunyn, Billroth, Pirogow Kussmaul, Lorenz, Nothnagel, and Wundt. The second part, in which the descriptions are taken from medical journals or textbooks deals with a similar variety of conditions, such as oxyuriasis (Heubner), cerebral thrombosis (Fowell), asthma (Trousseau), myotonia congenita (Thomsen), and various sexual disturbances by anonymous writers. The third part, which in our opinion and that of Professor Grotjahn, is the most valuable part of the work, consists of descriptions given at the writer's request by his medical acquaintances of various illnesses, such as those already mentioned and numerous others, such as cholelithiasis, renal colic, duodenal intubation, anaesthesia, migraine, otitis media, real and imaginary pregnancy and delivery. The object of the work is to emphasize the importance of the psychological aspects of the doctor's calling, which tends rather to be neglected in medical education, and to inspire the young practitioner, with a feeling of sympathy for his patient by a vivid presentation of what the doctor himself has to undergo when illness overtakes him.

[2] *Aerzte als Patienten. Selbstbiographien und Krankengeschichten in ärztlichen Selbstbetrachtungen*. Von Professor Dr. med. A. Grotjahn. Leipzig: G. Thieme. 1929. (8½ × 5½, pp. viii + 274. M.18, paper cover; M.19 bound.)

Dr. R. FLETCHER MOORSHEAD'S book, "*Heal the Sick*,"[1] will appeal chiefly to members of the Baptist faith. It is a detailed account of the history of the Medical Mission Auxiliary of the Baptist Missionary Society, of which Dr. Moorshead is medical secretary. He is a firm believer in linking up hospital and school with mission work.

Two of the three striking plays now published in a single volume[2] by JAMES BRIDIE, *The Switchback* and *The Sunlight Sonata*, have been produced by the Repertory Theatres of Birmingham and Glasgow. Each play recalls a predecessor at some point, yet each is sharply original. In *Switchback* the exactions of medical etiquette, as represented by Sir Anthony Craye, and the gross publicity imposed by Lord Pascal, the newspaper proprietor, and by Burmeister, the financier, combine to wreck the work and the soul of the honest idealist, Dr. Mallaby, who in the end refuses all reparation and departs to forget the ugly conditions of modern life among the dust of Palmyra. The author is, we believe, a member of our profession, but there are passages in this vigorous play which medical readers may find a little unreal. In *The Sunlight Sonata* Beelzebub and the seven Deadly Sins dispute with the three Christian Graces the disreputable sons of some typical members of the Glasgow bourgeoisie. Here the element of fantasy, uniting with the bitterness of the social attack, reminds one occasionally of Strindberg, though the admirable dialect of Beelzebub is sardonic in an entirely Scots manner. The brief scene called *The Pardoner's Tale* sets the Chaucerian story in a ruined changehouse on the road between Edinburgh and Perth. Here on a dark and windy night come three wild young men to find death in a sinister room. This macabre piece is written with extraordinary intensity. The peculiarly bitter tang of eighteenth century Edinburgh dissipation is well conveyed; and the lament of Philip Macgillivray, the Highland medical student, who looks like "a debauched Galahad," over the ironies of death, is hot and cold like a poem by Villon. A mediæval passion, strangely matching an extremely modern quality of mockery, gives James Bridie's work much dramatic value.

PREPARATIONS AND APPLIANCES.

A LARYNGEAL MUCUS EXTRACTOR.

DR. A. B. RUTAH, Enugu, writes: I desire to introduce a new pattern of "mucus extractor" for use in obstetrics, by means of which mucus can be extracted by suction from the mouth of the infant in a more cleanly and hygienic manner than heretofore, and without any risk of the mucus reaching the mouth of the operator. This new pattern has already been given a thorough trial in the Rotunda Hospital, Dublin, where it is now being used with the full approval of the Master.

The whole instrument is preferably made entirely of nickel-plated or other metal, and comprises two portions of tubing—a proximal portion fitted with a suitable mouthpiece, and a distal portion, perforated near its outer end and suitably curved to fit comfortably into the mouth of the infant. Both portions being connected by an intermediate chamber. This intermediate chamber is formed in two portions, which can readily be taken apart for cleaning purposes. Within the upper portion of the chamber, or "lid," there is provided a detachable "baffle" device in the form of a "dome" [illegible] disc, provided with a U-tube [illegible] the centre of the "dome" and is made so [illegible] lower portion of the suction tube while the [illegible] adjacent to the surface of the "dome" and a hole above its upper surface. This "dome" is adapted at its periphery to co-operate with or dip into an annular recess formed at the top of the lower portion of the chamber by the position therein of a conical annulus or ring. An effective trap of "baffle" is thus provided, which will prevent any mucus reaching the chamber from passing up the suction tube to the mouth of the operator since should any mucus tend to rise in the chamber it is thrown down by the conical annulus in the upper part of the chamber, and also by the dome now occupying the top.

It may also be pressure to state that since this extractor has been used at the Rotunda it has been uniformly satisfactory.

This new instrument is made and supplied by Messrs. Allen and Hanburys Ltd., 49 W. [illegible] Street, London, W.1

ACUTE POLIOMYELITIS.

An exhaustive review of the epidemiology of acute anterior poliomyelitis in recent years has been published in the February and March numbers of the *Monthly Epidemiological Reports* of the Health Section of the League of Nations. The article includes a general description of the past history of poliomyelitis and a detailed account of its incidence and mortality in various countries within the last two decades, and is illustrated by spot maps of important epidemics in England, Belgium, Holland, Sweden, and Rumania from 1926 to 1929. It should prove of the utmost value as a sequel to the masterly survey made by the late R. Bruce Low fifteen years ago.[1]

As is well known, Scandinavia, where epidemic manifestations were first noted, has suffered more than any other European country. The first serious outbreak occurred in Sweden in 1881, nearly 100 years after Michael Underwood published the earliest medical description of infantile paralysis under the heading "Debility of the lower extremities." Several epidemic foci were reported in Norway in 1894, and since then many epidemics have occurred in these two countries, the most important being in 1905 (1,199 cases) and in 1911–13 (9,018 cases). The great majority of the outbreaks of poliomyelitis in North America have occurred in the Northern States of the Union, and, as Bruce Low observed, the diffusion seems to have followed a course generally from east to west. A severe epidemic occurred in the State of New York in 1907, when 2,500 cases were reported. Between 1905 and 1909 the number of persons attacked in the United States was estimated at no fewer than 5,400. Another very serious outbreak followed in 1916, with upwards of 13,000 cases. During the past quarter of a century the incidence has fallen most heavily on the United States, but the distribution of the disease is world-wide. In northern countries it seems to have existed from far remote times, as is suggested by characteristic deformities of skeletons found in the cemetery at Herjolfsnes in Greenland, occupying the site of a native colony that had wholly disappeared; it is apparently represented also in an Egyptian stele of the eighteenth dynasty preserved at Copenhagen. Though the disease is much rarer near the Equator than in temperate climates, yet in the Northern Hemisphere it is most prevalent during the warm months. It exists also in the Southern Hemisphere, notably in Patagonia, South Africa, and Australia, and in New Zealand, where 1,018 cases with 123 deaths occurred in the epidemic of 1916, and 1,257 cases with 166 deaths eight years later. Whereas its incidence in northern latitudes reaches the highest point during August and September, in the south the peak occurs between December and May, the months corresponding to our summer and autumn. The case mortality has varied much in different countries and in different years, the disease being far more virulent in Sweden, the United States, and Canada, for example, than in Saxony or Rumania. "The average death rate from all forms is 12 to 13 per cent. Variations from this figure in different countries are apparently due not to any difference in the gravity of the disease, but to different methods of compiling statistics." In most epidemics a difference has been noted in the incidence of the disease in town and country, but there has been no constancy in the comparative prevalence of poliomyelitis in urban and rural populations. Though notification has been compulsory in England and Wales for some years past, many cases are never notified and estimates of incidence can only be approximate.

As regards the portal of entry of infection, the experiments carried out by Landsteiner and Levaditi many years ago proved that the virus was present in the tonsils or pharynx at the onset of the disease. Subsequently the part played by tonsillectomy in the development of acute anterior poliomyelitis was emphasized by Aycock and others, especially as the period which elapsed between tonsillectomy and the attack of poliomyelitis tallied with the incubation period of the disease. It is more likely, however, that the action of tonsillectomy is merely that of a wound which facilitates the entrance of the virus of poliomyelitis, as it does that of scarlet fever or other infections. The nature of the virus remains unknown, and the part played by the streptococcus described by Rosenow and others in the etiology is more than doubtful. The disease has been reproduced by intraperitoneal or intracerebral inoculation into the monkey and rabbit, but the virus is very quickly attenuated by passage through these animals. It has not been proved, however, that the substances inoculated contained the pathogenic organism; they may have contained the toxin alone. It is not certain whether the disease is transmitted by direct contact, or through the agency of fomites or of foodstuffs such as milk, or through other channels. Experimental evidence suggests that the virus is emitted and gains entry through the mucous membrane of the throat and nose. There is at present no biological test by which an early diagnosis of the disease can be made; its recognition has to be based on the clinical symptoms, and the diagnosis is only finally established on the occurrence of the paralysis.

Convalescent serum for the prevention or treatment of acute anterior poliomyelitis has been employed since 1910, when Netter, using the meningeal route, claimed good results from its use at the beginning of the illness, before the first symptoms of paralysis had appeared. The drawbacks to the method are: first, the difficulty of making a diagnosis before the appearances of paralysis, and, second, the difficulty of obtaining convalescent serum. Moreover, the absence of controls in all epidemics treated by this method deprives it of a firm scientific foundation. Serums have also been prepared by immunizing horses with material from the spinal cords of infected monkeys, or with the pleomorphic streptococcus isolated by Rosenow in the tonsils and central nervous system of poliomyelitis patients; but their value in the treatment of the disease is not yet firmly established.

LIGHTING AND WORK.

THE lighting of a factory or workshop is a matter for the special care of every employer and works manager, since it has an important bearing both on the health, safety, and efficiency of the worker and on the general output of work. The Home Office, through a departmental committee, has studied this subject extensively since 1913, and has issued several reports. These are summed up in Welfare Pamphlet No. 7, on "The lighting in factories and workshops," of which a new edition is now issued.[1] The document is a short

[1] The Lighting in Factories and Workshops. Third edition. Welfare Pamphlet No. 7. London: H.M. Stationery Office. 1930. (Pp. 25, 4d. net.)

and an effective presentation of the subject, which should be studied by every doctor connected with works as well as by the controllers of those establishments. The effect of lighting upon the industrial worker is material. Eyestrain and headaches are certainly caused by bad light. It has not been possible to trace specific cases of eye disease to this cause, save possibly in the instance of miners' nystagmus; but there are few conditions more mentally irritating than those associated with bad light, whether this is due to insufficiency or glare or confusing shadows. A worker continuously subjected to such adverse conditions cannot give the best work of which he is capable. Further, bad light is undoubtedly a factor in the incidence of accidents. A statistical investigation carried out by the committee shows that accidents of certain types occur more frequently during winter months, when the daylight hours are short. It is obvious that proper illumination of dangerous parts of machinery is an essential factor of safety.

Light is just as much a tool of the worker as any mechanical implement. Delicacy of work demands delicate tools, and light appropriate to the work is an essential tool: it is no less necessary in the coarser work than in the fine. Two forms of lighting must be considered—the general lighting of the shop sufficient for the safe movements of the worker, and the specific lighting of the benches or of the machinery used. Indications of the minimum requirements for floor lighting are given for different types of shops and passages. Bench lighting will also vary with the type of the work; it must be high where detail is fine. One of the most necessary precautions is the safeguarding of the eyes against glare. It has been a common practice in the past to attach new and powerful lamps to old fittings which were designed to carry totally different forms of illumination. For example, naked gas-jets have been replaced by incandescent mantles with a view to better lighting, but the effects are bad and wasteful unless care is taken to provide efficient reflectors. Worse effects follow when high power gas-filled electric lamps, with their great intrinsic brilliance, are substituted for the old carbon lamps without altering the small shallow reflectors which were appropriate for the carbon lamp. In these new and powerful appliances are to be found most satisfactory and economical forms of lighting, provided always that they are used with sense.

Of all forms of illumination there is none better than natural light. To secure the advantage of this the windows of factories should be large and well placed, and they should reach to the ceiling of the shop. It is essential that the windows should be cleaned frequently, otherwise the best efforts of the architect and builder will be nullified. Through a recent study of the output of hand compositors in printing offices it has been shown that if the artificial illumination is sufficiently strong (about 20 foot candles) the daylight standard of output may be reached. Obviously, the ideal to be aimed at, if only on the ground of economy, is good natural lighting, and every worker would probably prefer this even to the best artificial source of light. Under artificial illumination of a lower intensity, such as may commonly be found in factories, production drops. The following examples of this are given: in linen weaving, under artificial light, production fell off by approximately 11 per cent.; in silk weaving, a correspondingly fine process, 10 per cent.; in cotton weaving, where coarse material is used, 5 per cent. Such losses as these can be remedied. The advice of an expert illuminating engineer may be valuable, but often the remedies are quite simple and inexpensive.

At the Home Office Industrial Museum, in Horseferry Road, near Westminster Abbey, the lessons of this pamphlet may be seen demonstrated in such fashion that they are certain to carry conviction. This museum is an excellent piece of work, and its value is not sufficiently appreciated. It is open every weekday, and parties may have demonstrations arranged for them. Where workmen, from an innate conservatism, are inclined to resist innovations there is nothing more calculated to secure their speedy conversion than a visit to this museum.

PSITTACOSIS.

In the comprehensive study of psittacosis compiled by Drs. R. Hutchison, R. A. Rowlands, S. Levy Simpson, and Professor H. M. Turnbull, which was published in the *British Medical Journal* of April 5th (pp. 633–646), the suggestion was made that a filterable virus might be responsible for this condition. In support of this view were cited the investigations carried on at the London Hospital by Drs. S. P. Bedson, G. T. Western, and Levy Simpson. The Health Organization of the League of Nations has now issued an illustrated memorandum[1] on the history and etiology of the disease, and the same conclusion as to its causation is reached, Nocard's bacillus (*B. psittacosis*), and other bacteria which were formerly suspected, being regarded as not concerned in their usual form, though it is agreed that the filterable virus is very closely connected with the group of the typhoid and salmonella organisms. This conception helps to explain the partial resemblance of the clinical symptoms to those of enteric fever, and the incipient agglutination of the blood of some psittacosis cases to bacilli of the typhoid group. The disease is probably a genuine septicaemia, often complicated by toxaemia; the toxin seems to have a special affinity for the nervous centres, which are strongly affected in the hypertoxic forms. This memorandum gives a detailed account of the history of the recognition of psittacosis, the sources of infection, the symptomatology, and prophylaxis. The duration of the incubation period is stated as being generally 8 to 15 days, but it may be shorter, more rarely longer; the onset is abrupt. In favourable cases the symptoms begin to subside about the tenth day. In fatal cases (35 to 40 per cent.) there is often a crisis about the fourth or fifth day; the nervous symptoms predominate; there is pronounced drowsiness, high fever, and great prostration; the pulse rate increases; and death supervenes from cardiac weakness, sometimes even before the pulmonary symptoms have reached their maximum. In other cases death does not take place until the tenth or twelfth day of the illness, with symptoms of cardiac weakness and broncho-pneumonia, or from pulmonary oedema. Uraemia may also be the cause of death. There is often a relapse at the moment when the temperature begins to fall. Among the practical steps recommended for adoption by A. Roubakine, whose name is appended to the memorandum, are restriction of the admission to European countries of parrots and parrakeets, together with prohibition of the importation of parrots' wings, and all parts of their dead bodies. The organization of a competent veterinary service is advised, and it is suggested that bird shops should be classed among the unhealthy premises. A final proposal is that psittacosis should be included in the list of compulsorily notifiable diseases. The Argentine outbreak of July and August, 1929, is not regarded as the initial focus of the recent

[1] League of Nations. Epidemiological Report. R.E. 137. Geneva, April 15th, 1930. London: Constable and Co. Ltd. 6d.

"epidemics" in America and Europe; it appears to have followed the importation of a consignment of sick parrots from the Amazon district in Brazil.

The proposal for restricting the importation of parrots has already been adopted by the Ministry of Health. A circular issued on April 28th states that the Minister is satisfied that for the protection of the public health it is necessary to prohibit for the present the importation into this country of parrots and all birds of the parrot species. With this object regulations have been made and will take effect on May 20th. The regulations do not forbid the importation of any parrot which is proved to the satisfaction of the medical officer of health to be required for purposes of medical or veterinary research, or which is consigned to the Zoological Society of London or to a person specially authorized by the Minister to import parrots otherwise than for sale. A parrot is defined as a bird of the species Psittaciformes, and includes any of the birds commonly called parrots, parrakeets, lovebirds, macaws, cockatoos, cockatiels, conures, caiques, lories, and lorikeets. Masters of ships must notify the Customs and Excise officers of any parrot on board a vessel approaching a port in England and Wales. If the parrot is diseased or is associated with cases of human illness the medical officer of health may forthwith cause the bird to be destroyed or otherwise disposed of to his satisfaction. Although no case of psittacosis has so far been reported in Scotland, corresponding regulations have been made by the Department of Health prohibiting the importation of all birds of the parrot species into Scotland as from May 20th.

SLEEP IN HOSPITALS.

THE Central Bureau of Hospital Information (19, Berkeley Street, W.) has just published in tabular form the replies received from the authorities of 63 provincial general hospitals to a questionary designed to elicit information about the time at which work starts in the wards, and opinions on the desirability of adopting a procedure whereby patients would not be disturbed until 7 a.m. From a study of the figures it seems that in general the present routine is somewhat as follows: In most of the hospitals the day nurses start duty at 7 a.m., and as the night nurses do not go off till 8 or 8.30 the duties of the two staffs overlap for a period of one to one and a half hours. Work begins in the wards of 45 of the hospitals from which replies were received before 6 o'clock, and in the remainder at 6 o'clock or later. Between the beginning of work and breakfast there is an interval varying up to two and a half hours, but in most cases it is from half an hour to one hour. The hour fixed for the visits of the honorary medical staff varies in these hospitals from three to six and a half hours after the beginning of work, but in the majority the interval is four to five hours. The routine thus appears to be pretty uniform, but there are sharp differences of opinion about the desirability of effecting a change. The authorities favouring a retention of the present system try to justify their preference by reasons that fall roughly into three groups. They state, first, that there is no hardship in the present arrangement, though they concede that very sick patients should receive special consideration; secondly, that the proposed change would not allow a sufficient interval between the time at which work starts and the hours fixed for the visits of the medical staff; and, thirdly, that most of the patients are accustomed to early rising. It would be interesting to know how, under existing arrangements, the most careful consideration could ensure that some patients should be awakened and not others; our own experience is that as soon as activity begins in the ward patients are liable to be disturbed, whether the staff wishes them to go on sleeping or not. Unless, therefore, special wards are set aside for patients needing extra sleep we cannot see how the existing routine can fail to inflict hardship on, at any rate, a proportion of the patients in the ward. We find it difficult to consider seriously the suggestion that the visit of the honorary medical staff must take place at some fixed and immutable hour, to which the times set aside for all other activities in the ward must be adapted. Those who have watched the performances of Grock may recall the great moment when, his stool being too far from a grand piano, he exerts himself stubbornly, but without success, to put things right by moving the grand piano up to the stool. We cannot but feel that the honorary staffs, while grateful for the consideration shown to them by the authorities administering their hospitals, would be the first to say, "Move the stool, Sirs, move the stool." We must concede the truth of the statement that most patients are accustomed to early rising; so, however, are they to working hard for eight hours a day, and no doubt to all kinds of practices which, while appropriate to them when they are in health, might be harmful in time of sickness. A number of hospital authorities suggest that some patients would not appreciate a later waking hour, as they settle down to sleep at 8 p.m.; but we cannot help wondering what consensus of opinion would be obtained if the Central Bureau of Hospital Information or some other body invited patients themselves to state whether they find the existing procedure desirable, and, if not, what changes they would propose.

THE WORLD OF THE BLIND.

THE mental make-up of the blind man has received the attention of not a few scientists and psychologists, and for the most part their conclusions do not endorse the more fantastic sensibilities with which he has been credited. But there have been few records that seek to show us how the blind man registers his impressions of the world about him. Perhaps the best of those that have been published is H. G. Wells's story, *The Country of the Blind*. There has now been issued a book by Professor Pierre Villey on *The World of the Blind*.[1] The author lost his sight at the age of four and a half years. In his complete darkness "no visual impression could come to awaken sleeping memories." Yet he so far overcame his disability that he now holds the Chair of Literature at Caen University, and his book has been awarded a prize by the French Academy of Moral Science. He records with delight the complete transformation in the circumstances of the blind. In former times they were credited with almost occult faculties, but their real abilities were neglected. Now they can receive a culture adapted to their needs and lead a useful existence. But the prejudice of the public dies hard. There is still the idea that behind sightless eyes and a face without animation everything is dulled, that the intelligence, the will, the sensations, and the faculties of the soul are numbed and, as it were, stupefied. The purpose of the author is to show how false is this impression. He complains that many who have investigated the mind of the blind have not distinguished between loss of sight and loss of other powers. There are blind and blind. Many are blind because of constitutional disease—tuberculosis, syphilis, and congenital and inherited defects. Disabilities arising from these general causes are not properly to be ascribed to the blindness. If the accident which has destroyed the sight was confined to the eye itself and its immediate surroundings, and has not touched the brain, the integrity of the intelligence is safe. Professor Villey agrees with Aristotle, who said that sight was the most important of all the faculties for the needs of animals, but that for intelligence hearing was the more necessary. "It is hearing which serves as the real bond between minds. In

[1] *The World of the Blind*. A Psychological Study. By Professor Pierre Villey. Translated by Alys Hallard. London: G. Duckworth and Co., Ltd. 1930. (7s. 6d. net.)

manual work, the deaf man who sees is superior to the blind man. From the intellectual point of view, I am convinced that the position of the blind man who hears is preferable to that of the deaf man." He reviews in several chapters investigations that have been made on the intelligence of the blind. He agrees that there is no truth in the alleged substitution of senses in the blind—that is, the compensatory increase of sense of hearing and touch. Tested with the aesthesiometer the blind man shows no greater acuity of perception than the sighted. "A singular thing, even, is that the forefinger of the blind—that is, the reading finger and the one that is exercised the most—is less sensitive than the other fingers. Also, a given noise is not noticed by a blind person at a greater distance than by a person who sees." Professor Villey's summing up of the discussion of what sort of spatial images are formed in the mind of the blind is good. "He has what I should style a veritable *tactile sight*. The word *sight* is the only one which renders these apparitions which spring up in the brain, free from all conscious muscular impressions, from all representation by fingers and hands. They are less rich, certainly, less complex, and considerably less extensive than visual images, but, like them, one and many at the same time, are perceived, in their entirety and also in detail, by the inner eye of consciousness." The attitude that normal folk should hold to the blind he thinks may be summed up thus: "On the door of one institution for the blind are these words: 'Visitors are requested not to utter any expressions of pity.' The director of that school is certainly a psychologist." The book is dedicated to the memory of Sir Arthur Pearson, who, himself blind, did a great work for the blind of all countries.

APTITUDE TESTS FOR MEDICAL STUDENTS.

THE present Chairman of Council of the British Medical Association some years ago, when giving his presidential address to the Metropolitan Counties Branch entitled "The Psychologist in Public Life" (*Journal*, July 30th, 1921), pointed out that it was desirable to gauge as accurately as possible four things: attainment, intelligence, aptitude, and character, and that an attempt at the measurement of each of these had, in fact, been made. Dr. Brackenbury then stated that "success with the exact measurement of aptitude, though considerable, has not been so ample as with the measurement of intelligence," that "clearly, the higher we go up in the vocational scale the more the measurement required becomes one not of mere aptitude but of character," and that "to estimate the varieties of excellence of character, and to investigate the causes of super-excellence, may be of at least equal national or public importance as to detect or to measure its defects." After referring to the often unsatisfactory character of what are known as testimonials, or certificates of moral character, he continued: "How much more valuable would be the report of a scientific investigation by a skilled psychologist standardized by reference to a recognized scale, especially if such a report were universally required for entrance into any of the professions or for the holding of any position of responsibility or trust. . . . Seriously, it is quite possible that what is now true of the measurement of intelligence may some day be true of the measurement of character, and then the exact method would be preferable to the happhazard and the omission of certain important bodies of public persons from these tests would be unjustifiable." It is interesting to note that—of course in America—an attempt is being made to-day to apply these principles and methods to entrants to the medical profession. The problem as presented to the deans of the medical schools of the United States is certainly one calling for careful consideration. For the year 1929–30 there were 13,569 applicants for admission, and of these only 7,019 could be accepted. The problem is to select the best seven thousand. It is inevitable that a large proportion of the most promising students apply to some half-dozen of the schools with the highest reputation, but this makes the problem of selection for the other schools all the more serious. Apart from social or family pressure in a number of individual cases, the means of selection have hitherto usually been: (1) the number of terms of pre-medical study already followed, (2) attainment in pre-medical subjects. Though, as might be expected, the latter of these is more reliable than the former, neither is at all satisfactory in view of the "mortality in the last five graduating classes in medical schools. In these classes more than one-fifth of all those who began work in the freshman year were unable to complete the four-year course." The elimination of the feeblest students begins even in the first year. For the past two or three years an attempt to apply systematic "scholastic aptitude tests" of ability to pursue successfully a medical course has been made to a large number of entrants, and the results of this attempt are set out in an article in the *Journal of the Association of American Medical Colleges* for March last. The details of the tests are not given; it may be that after all they were tests of attainment and of intelligence rather than of real aptitude. In any case they seem to have resulted in the discovery of a better criterion than those previously applied. "The relative efficiency of the three criteria mentioned are: number of entrance credits, 22 per cent.; pre-medical grades, 48 per cent.; scholastic aptitude scores, 63 per cent." The result of combining the last two criteria is said to be 74 per cent. A further criterion combined with these—an interview definitely directed to certain points and marked accordingly, with more than one member of the school staff—may obviously be of much value. But as long as we have men of slow mind and men of quick mind, and as long as we have many personal characteristics in addition to scholarship which make for success in the medical profession, so long will all these tests fail in a number of cases. Perhaps one of the really valuable suggestions made in the reported discussion on this subject was that the deans of the institutions should themselves be subjected to the "scholastic aptitude" test, and that, provided they made a score of over 12 per cent., they should be continued in office!

SIR EDWARD POLLOCK.

THE obituary notices of the late Sir Edward James Pollock which have appeared in the daily press remind us of the well-nigh forgotten fact that he was a member of our profession, who practised for several years in London before he was called to the Bar and joined that other profession which had afforded opportunities of distinction to several members of his family. Sir Edward Pollock was not the only one of the descendants of that remarkable saddler of Charing Cross (of whose sons one became Chief Baron and another a Field-Marshal) to adorn the medical profession. Fifty years ago George Pollock of St. George's Hospital was one of the last representatives of the pre-Listerian tradition of surgery. Another contemporary Pollock, Arthur Julius, was physician to Charing Cross Hospital, and a member of the next generation was W. Rivers Pollock, obstetric physician to Westminster Hospital, whose comparatively early death as a remote result of thrombosis of the inferior vena cava was widely deplored. The third generation of medical Pollocks is represented by his son Humphrey Rivers, who practises in Kensington. Sir Edward had reached the age of 89. He was the ninth son of the Chief Baron, whose family of twenty-four children included various well-known men. He became M.R.C.S. in 1853, L.S.A. in 1855, and F.R.C.S. in 1858. He practised, but soon after he became a Fellow he paid a prolonged especially in ophthalmic surgery, in London for a time,

visit to the United States. On his return he gave up medical practice and decided to read for the Bar, to which he was called by the Inner Temple in 1872. In 1897 he was appointed one of the three official Referees of the Supreme Court, and retained the post until 1927, when he was eighty-six years of age. He had no reason to regret his change of calling fifty-five years before. As we noted on the occasion of his death last year, that most distinguished jurist, Viscount Finlay, of Novar, was also a member of our profession, although it seems that he never practised. His name disappeared from the *Medical Register* years ago, unlike that of Sir Edward Pollock, which appeared in the latest issues of the *Register* and of the *Medical Directory*.

ROCKEFELLER MEDICAL FELLOWSHIPS.

THE Rockefeller Medical Fellowships for the academic year 1930-31 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 1st, 1930. These Fellowships are provided from a fund with which the Medical Research Council has been entrusted by the Rockefeller Foundation. Fellowships are awarded, in accordance with the desire of the Foundation, to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles. In special circumstances the Fellowships may be tenable at centres of research not in America. A Fellowship held in America will have the value of not less than £350 a year for a single Fellow, with extra allowance for a married Fellow, payable monthly in advance. Travelling expenses and some other allowances will be paid in addition. Full particulars and forms of application are obtainable from the Secretary, Medical Research Council, 38, Old Queen Street, Westminster, S.W.1.

TUBERCULOSIS CONFERENCE.

THE sixteenth annual conference of the National Association for the Prevention of Tuberculosis will be held, from July 3rd to 5th, in the Great Hall of the House of the British Medical Association, Tavistock Square, W.C.1. It is proposed on this occasion to devote special attention to the effects on the tuberculosis campaign of the Local Government Act, 1929. Sir George Newman will open the discussion on this subject, and will be followed by Dr. John Parlane Kinloch, Chief Medical Officer of the Department of Health for Scotland. The conference is open to all interested in tuberculosis, on payment of a fee of one guinea, for which is supplied also a copy of the report of the proceedings. Reduced railway fares to London will be available, and sanction has been given to the reasonable expenses of delegates from local authorities who will be attending the conference. Inquiries should be addressed to the secretary of the National Association for the Prevention of Tuberculosis, Tavistock House North, Tavistock Square, W.C.1.

INTERNATIONAL VETERINARY CONGRESS.

FROM August 4th to 9th, the eleventh international veterinary congress will be held in London at the Central Hall, Westminster, and it is anticipated that over a thousand delegates will attend from the Dominions, Colonies, and foreign countries. Many matters of importance to medical science in general will be discussed—for example, foot-and-mouth disease, vaccination against tuberculosis, veterinary science in relation to public health (with special reference to production and distribution of meat and milk), variola in domestic animals, control of dissemination of anthrax by animal products, vaccination against rabies, anthelmintics, and control of trypanosomiasis. The congress will be opened by the Minister of Agriculture on August 4th, and meetings will occupy the entire week. For the entertainment of delegates a number of excursions and social functions have been organized, including a conversazione at the Natural History Museum, a reception at the Guildhall, and a banquet by the Government.

LEPROSY IN THE BRITISH EMPIRE.

THE annual report for 1929 of the British Empire Leprosy Relief Association, which is entitled *The Fight Against Leprosy*, is in many ways a model of what such publications should be. A clear account is given of the prevalence of leprosy, and of the efforts being made to eradicate it in different parts of the Empire. Perusal of the report gives a vivid impression of the amount of specialist knowledge at the service of the association, the active and extensive research which is being conducted, and the sound lines on which treatment is being administered in various localities. The hopefulness of the whole campaign is made clear, as is also the immediate importance of increasing the financial endowment so that still greater progress may be made in the next few years. The valuable quarterly periodical of the British Empire Leprosy Relief Association is supplied without charge to workers in the mission field, and to others who are concerned with the fight against this disease; grants are made to assist missionaries of all denominations in treating leper patients, and curative drugs are supplied. In contrast with the success achieved by the Indian branch, which was inaugurated by the Marquess of Reading during his Viceroyalty, the British possessions in Africa are still seriously hindered by lack of funds in their efforts to deal effectively with the leper problem. Since there is no possibility of money being raised locally in that continent on anything approaching the Indian scale, assistance in this respect must necessarily come from Great Britain.

DR. ROSS MITCHELL, whose literary skill is known to our readers through his series of articles on Winnipeg, contributes to the April issue of the *Canadian Medical Association Journal* an interesting paper on the remains of William Harvey. "It would seem," he says in conclusion, "a fitting thing to restore to its former appearance the church which enshrines the remains of one whose name shines brightest in the annals of British medicine." In an editorial note Dr. Nicholls commends the project for restoring the tower of Hempstead Church, Essex, of which an account appeared in our issue of December 7th last. Subscriptions to the Harvey Memorial Fund may be sent to Dr. Arnold Stott, 58, Harley Street, W.1.

AT the Imperial Agricultural Research Conference held in 1927 it was recommended that each research institution of the Empire should forward all its publications on preservation and transport of food to the Low Temperature Research Station of the Department of Scientific and Industrial Research at Cambridge, which would, in its turn, issue from time to time indexes of the literature on food investigation, consisting of elaborated titles of useful publications. The second of these indexes, compiled by Agnes Elisabeth Glennie, B.Sc., has just appeared (H.M. Stationery Office, 1930, 2s. net). It contains carefully classified references to the relevant literature in English, French, German, Italian, and other languages, and includes brief abstracts of papers appearing in periodicals from all parts of the world. The Department of Scientific and Industrial Research proposes to issue each year one volume, consisting of two numbers, dated March and September respectively, and to include in the first number of each volume a brief review of the previous year's progress in the subject.

EXAMINING BOARD IN ENGLAND.

REVISED REGULATIONS FOR THE CONJOINT DIPLOMAS.

A NEW edition of the regulations governing the professional examinations for the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England embodies certain important alterations which come into force on July 31st next. The chief of these relates to the conditions under which graduates of foreign universities recognized by the Examining Board in England—universities in fifteen European countries and the United States—are to be admitted to the examinations. Hitherto such graduates have been required, provided certain conditions are fulfilled, to take the Final Examination only, but in future they will have to pass the First Professional Examination (anatomy, physiology, and pharmacology and materia medica), and subsequently to complete twelve months of hospital practice in a recognized medical school and hospital in this country before being admitted to the Final. The undergraduates of such universities are required to complete the full curriculum of 33 months for the Final Examination at a recognized medical school and hospital in this country, after passing the First Examination in accordance with the regulations.

Some new special regulations affect candidates who hold a practice qualification granted in India, other than the degrees of Bachelor or Doctor of Medicine and Surgery in one of the Indian universities which have been recognized by the Royal Colleges. Such candidates are required to pass a recognized preliminary examination in general education, to pass the First Professional Examination, and, after passing Section I of that examination, to complete two years' practice in a recognized medical school and hospital in this country. Those who have taken a curriculum of not less than five years in a recognized medical college (as distinct from an unrecognized medical school), and hold a qualification, come under the same conditions as the preceding, except that exemption is granted from Section II (pharmacology and materia medica) of the First Examination, and only twelve months of hospital practice (instead of two years) is required. Other conditions attach to candidates who have completed the curriculum at a medical school or completed a part of the curriculum at a recognized medical college, but have not obtained a qualification in India.

Members of recognized universities in the British possessions, having passed an examination at their universities and completed the required curriculum, are admissible to the Final under the same rules as have hitherto applied to all recognized universities outside this country, including foreign universities; and candidates holding the diploma of the National Board of Medical Examiners of the United States come into the same category. The regulations for members of English, Scottish, and Irish universities remain substantially unaltered.

Among relatively minor changes is a recasting of the regulation which lays it down that the course of study for the First Professional Examination may be commenced before Part II (Biology) of the Pre-Medical has been passed, but that not less than three terms of study of anatomy and physiology must be completed after such examination. The new regulation runs:

> The study of anatomy and physiology will not be recognized until Part I of the Pre-Medical Examination has been passed, and not more than two terms of such study will be recognized before Part II of the Pre-Medical Examination has been passed.

Among the prescribed courses which candidates must have attended before being admitted to the Final is the addition of a course of instruction in practical pharmacy, a subject transferred from its former place where it preceded the taking of Section II of the First Examination. In its new place it is the fourteenth of the courses for attendance at which the candidate for the Final will be required to produce certificates. The course may, however, be taken before the First Examination is passed.

A copy of the regulations and synopses may be obtained from the Examining Board (8–11, Queen Square, Bloomsbury, W.C.1).

Diploma in Gynaecology and Obstetrics.

The regulations for the new Diploma in Gynaecology and Obstetrics (D.G.O. R.C.P. and S. Eng.), the first examination for which will be held in October next, have also been issued by the Examining Board in England. Those eligible for admission to examination must have held a degree in medicine and surgery recognized by the Board, or a qualification registrable in this country, for not less than three years. The subjects of the examination are gynaecology and obstetrics (including pathology, histology, and bacteriology in relation to these subjects), and ante-natal, post-natal, and infant welfare work. The examination is written, oral, and clinical, but only those candidates are admitted to the clinical who satisfy the examiners in the written and oral. A form is issued on which particulars have to be given and certified as to resident appointments in the gynaecological and obstetrical department of a recognized general hospital, in a gynaecological hospital, or a maternity hospital, or as to registrarship or clinical assistantship held in such institutions, together with particulars as to regular attendance, with responsible care of patients, at recognized ante-natal, post-natal, and infant welfare clinics during twelve months. It is added that these conditions of study may be modified in the case of a candidate who has carried out original investigations or written a thesis on some subject in gynaecology or obstetrics, or whose studies have extended over a prolonged time without fulfilling the exact conditions set out; but exemption will not be granted from any part of the examination.

England and Wales.

A Hunterian Evening.

SEVERAL interesting circumstances marked the annual meeting of the Hunterian Society of London, which was preceded by a dinner, at Simpson's Restaurant in Cheapside, on April 28th. One of these was the reading of a letter from Dr. Gustave Monod stating that he and Dr. Ferreyrolles, who were recently made honorary members of the society, had started a fellowship of similar character in Paris. The French society had taken for its legend "*Au carrefour de Cos*," signifying that under the inspiration of Hippocrates its members would take their stand where all the roads of medicine met, ready to investigate all methods of treatment, whether or not they were taught in the schools. The first president would be Dr. Ferreyrolles, who had one of the most unbiased minds in the French profession, and his presidential address would be on the philosophy of Chinese medicine. A standing invitation was given to members of the Hunterian Society who might be visiting Paris to consider themselves members of the French body. The Hunterian Society sent a message of greeting to its Parisian offspring. Another event of the evening was the presentation to the society by Dr. Irwin Moore, its treasurer, of an excellent copy of the famous picture at The Hague, "The School of Anatomy," by Nicholas Tulp, after Rembrandt, and also the presentation by the same donor of a number of books for the library, including the first edition of Culpeper's *Pharmacopoeia*, dated 1653. The Royal Society of Medicine possesses what has hitherto been thought to be the first edition, dated 1654, but Dr. Irwin Moore was assured that the one he now gave to the society was an earlier print. The society then proceeded to the election of its officers, and Professor A. W. Sheen was unanimously voted to the presidency, the first time that a president has been chosen from outside London. A hearty vote of thanks was accorded to the retiring president, Dr. Ernest Young, and to Mr. W. E. Tanner, who is relinquishing the honorary secretaryship.

The remainder of the evening was occupied with a cinematograph demonstration by Mr. Mortimer Woolf illustrating the operation of cholecystectomy. A two-reel film, the admirable production of the medical department of Kodak Limited, showed every detail of the operation as conducted by Mr. Woolf, including the placing of the patient in position, with the air pillow under the lower ribs so as to bring the liver and other organs nearer to the surface, the division of the rectus sheath, the picking up of the peritoneum, the displacement of the liver by traction and adequate exposure of the gall-bladder, the division of the peritoneum at the neck of the gall-bladder, continued into the small omentum, the insertion of forceps into the foramen of Winslow, a blunt dissection exposing the junction of the cystic, common, and common hepatic ducts—a crucial step in the operation—the isolation of the cystic duct, with two ligatures placed around it, the exposure of the cystic artery, the suturing of the peritoneum

over the common bile duct, and all the manipulations preceding and following the removal of the gall-bladder. The film also showed the exploration of the rest of the abdomen. A hole was found in the great omentum and the band was excised; the appendix also was found to be thickened, and was removed. In the course of some discussion following the exhibition Mr. Ivor Back said how much he had been impressed by the technique of the operation as demonstrated, but he thought Mr. Woolf would agree that he was exceptionally fortunate in his patient, who was a very thin person, whereas a large proportion of gall-bladder cases were in extremely stout persons, rendering the operation proportionately difficult. He himself was faced continually with the impossibility of performing—as was his ambition—the classic operation, and he could only remove as much of the gall-bladder as possible by stripping it down from the fundus. He frequently performed a partial cholecystectomy, leaving the neck of the gall-bladder, which afterwards formed a "fibrous blob." In reply to various points, Mr. Mortimer Woolf said that the time taken over the operation was roughly forty-five minutes. He was no advocate of rapid operations, though he agreed that no time should be wasted. One speaker had questioned his procedure in first removing the gall-bladder before exploring the rest of the abdomen. But, after all, this was an operation definitely for the removal of the gall-bladder, and he thought it preferable to undertake that procedure first, for one never knew whether the condition of the patient would permit of continued manipulation, and if the secondary thing were done first the surgeon might be faced with the necessity of closing the wound with his real objective unattained. He added that in the particular case shown the patient had suffered from severe attacks of what appeared to be cholecystitis. He believed that such attacks might occur, and at first clear up completely without giving rise to thickening of the gall-bladder walls or to formation of stone, and while he agreed that the gall-bladder certainly should not be removed without justification, he thought it wise to bring about removal before any catastrophe occurred, and, indeed, it was his view that intervention might well take place earlier than was customary in these cases. In addition to frequent attacks of cholecystitis, the patient had an enlarged cystic gland and other signs of inflammation. The gall-bladder when opened showed a definite polypoid mucous membrane. He agreed that, owing to the type of patient, the case was easier than many which presented themselves for operation, but on that account it lent itself admirably to the classic operation which it was desired to show by cinematograph for the purposes of surgical teaching.

Sanatorium Treatment of Tuberculosis.

The new county sanatorium at Black Notley, Essex, was opened on April 26th by Mr. Arthur Greenwood, Minister of Health, who commented on the declining death rate from all forms of tuberculosis since the end of the war. Although the death rate from tuberculosis in 1929 was 44 per cent. less than in 1918 about 36,000 people, he said, died every year from tuberculosis in England and Wales. It was not one of the diseases that could be cured by ordinary medical treatment, but he thought that, if every possible effort was made, it would be eradicated from this country. Sanatoriums could not provide assistance of a permanent nature, as patients, on leaving them, returned to unfavourable conditions. It seemed a little short-sighted for money to be devoted to the building and maintenance of sanatoriums when next to nothing was done to provide proper after-care treatment. He hoped that attention would be given to this problem. The Essex County Council was to be congratulated on having made special provision for the needs of women, as the incidence of tuberculous disease among young women in the county was higher than it ought to be.

The new sanatorium, which has a site of 25 acres, has been built to provide accommodation for women and children suffering from pulmonary tuberculosis and for children suffering from non-pulmonary tuberculosis. The general level of the ground slopes gradually towards the south, and the various buildings are laid out with a south-east aspect. Two children's pulmonary pavilions, one for boys and one for girls, have been erected, each accommodating 25 beds. Similar provision has been made in the two adult pavilions. An isolation pavilion contains 6 single bed wards, and two surgical pavilions, fitted with adjustable sun blinds, each accommodate 31 patients. All the pavilions have wide verandahs. The south walls of the two classrooms in the school block are formed by large folding doors, which allow the maximum of light and air. For the recreation of patients a cinematograph apparatus and a loud speaker have been installed in the King Edward VII memorial hall, which has seating accommodation for 200. In addition, four tennis courts have been laid out for the use of patients and staff. The total cost of the sanatorium, including site, buildings, services, and equipment, is approximately £100,802.

Birmingham Hospitals Centre.

A handsomely illustrated booklet has now been issued describing the scheme for establishing a large hospital centre on 150 acres of land situated north-west of the university buildings at Edgbaston, the freehold having been presented by Messrs. Cadbury Brothers, Ltd., to the City of Birmingham. A general hospital of 740 beds is to be erected, each unit of 60 being complete with all the necessary services. Seven operating theatres will be provided, and arrangements are being made for open-air treatment and the various special departments. A block accommodating 100 beds will be erected for paying patients, 50 of these beds being placed in single rooms. The new medical school of the university will occupy the south part of the site, and the cost of its maintenance will be borne by the university authorities. The scheme is being actively and generously supported by the existing hospitals of Birmingham, including the General and Queen's Hospitals. The estimated cost of the whole undertaking is about £1,250,000, and an appeal is being made to the city to ensure the construction of a medical centre which in size, equipment, general convenience, and economical arrangement will be in the front line of hospital progress.

St. Bartholomew's Hospital: New Block.

In connexion with the public appeal on behalf of St. Bartholomew's Hospital a pamphlet has been written by Mr. A. F. Shepherd, giving an account, in the form of a descriptive tour, of the new extension, which comprises six operating theatre suites and 250 surgical beds. The opening chapter is headed by three lines written by the late Poet Laureate, Dr. Robert Bridges:

> Hardly can I, who so many years eagerly frequented
> Bartholomew's fountain, not speak of things to awaken
> Kind old Hippocrates.

Historical notes follow indicating the gradual growth of the hospital during the past 200 years. Emphasis is laid on the strict economy that has been observed in providing the very necessary new buildings without stinting the equipment required for first-class surgery and nursing, or depriving the patient of every possible safeguard, comfort, and convenience. Details are given of the many ingenious devices by which these facilities have been rendered possible, and there are numerous hints of the scientific developments which have caused the medical treatment of the present day to be so vastly ahead of that of only a few years ago.

The Harrison Chemical Prize.

At the recent annual general meeting of the Chemical Society the prize and plaque to perpetuate the memory of Edward Frank Harrison, director of chemical warfare during the war, was presented to Reginald Patrick Linstead, D.Sc. This prize is awarded every three years to the chemist, not over 30 years of age, who is judged by a committee consisting of the presidents of the Chemical Society, the Society of Chemical Industry, the Pharmaceutical Society, and the Institute of Chemistry to have made the most meritorious original contributions to chemical science during the previous five years. The president of the Chemical Society, Professor J. F. Thorpe, in presenting the prize, said that it was seldom that a research worker within the age limits demanded by the trust was found to have struck out an original line of investigation for himself; usually he was content to elaborate and extend the research problems on which he had been trained. Dr. Linstead, however, had done some important and original

work on substances exhibiting tautomerism (the property in some chemical bodies of behaving in different reactions as if possessed of two or more different constitutions), and had supplied a method whereby the close and quantitative study of some of these fundamental phenomena could be effected. Professor Thorpe added that the prize was founded to commemorate an exceptional man, who gave his life for his country just as surely as if he had been on the field of battle, and he hoped that Harrison's high sense of service and devotion to duty would be an example to all who won or competed for this prize. It may be recalled here that Harrison was associated with the *British Medical Journal* for some years, and undertook the series of analyses of proprietary articles afterwards collected and published by the British Medical Association in the two volumes *Secret Remedies* and *More Secret Remedies*, now out of print. He also gave admirable evidence on behalf of the Association before the Select Committee on Patent Medicines.

Welsh Board of Health.

The Minister of Health has decided to restore the chairmanship of the Welsh Board of Health, and has appointed to the post Mr. John Rowland, C.B., C.B.E., M.V.O., a member of the Board and Deputy Controller of Insurance. The Board will henceforth consist of three members: Mr. John Rowland; Dr. Llewelyn-Williams, medical member; and Mr. Howell E. James, Administrative Officer for Public Health and Finance.

Central Midwives Board.

At the April meeting of the Central Midwives Board for England and Wales it was agreed to send a letter to the town clerk of Birmingham approving a continuance of the present arrangements for the training of midwives until the autumn, when the pupils of Dudley Road and Selly Oak Hospitals would be expected to attend the course of lectures at Birmingham University. In reply to a letter from the West Derby Guardians, the Board stated that the question of the administration of anaesthetics to patients in the final stages of childbirth was not within its jurisdiction; as long as the training rules and instructions were carried out the Board was satisfied, but it asked to be informed if any steps to the contrary were taken. The Pharmaceutical Society invited the Board to join with it and the Disinfectant Manufacturers' Association in the preparation of a specification for a standard preparation of lysol for medical purposes, but the Board, while agreeing that such action was desirable, decided that it was not a body expert in the subject-matter to be discussed, and on that account could not take part in the proposed conference.

Scotland.

Aberdeen Chair of Medicine.

THE regius chair of medicine in the University of Aberdeen, rendered vacant by the resignation of Professor Ashley Watson Mackintosh, has been filled by the appointment of Leybcurne Stanley Patrick Davidson, B.A., M.D., F.R.C.P. The appointment is made by the Crown on the recommendation of the Secretary of State for Scotland. The new professor is the second son of Sir Leybourne Davidson of Huntly Lodge, Aberdeenshire; he was born in 1894, and from Cheltenham College went to Trinity College, Cambridge, where he took the B.A. degree. He began to study medicine at Edinburgh in 1911, but his medical course was interrupted by the war, and he served for three years with the Gordon Highlanders. Being severely wounded, he was invalided out of the Army, and resumed his medical classes at Edinburgh, where he graduated M.B., Ch.B., with first-class honours, in 1919. On taking the M.D. degree in 1925 he was awarded a gold medal for his thesis. Having acted for a time as resident in the Royal Infirmary he became assistant in the bacteriology department of the University, a post which he held for three years. In 1927 he was appointed assistant physician to the Royal Infirmary of Edinburgh, and lecturer in systematic medicine in the University. Since 1926 Dr. Davidson has been engaged in research work under a grant from the Medical Research Council. He has published numerous papers on subjects connected with bacteriology, gastro-intestinal disorders, and disorders of the blood, and lately brought out, along with Emeritus Professor Gulland, a book on pernicious anaemia, presenting recent views on the pathology and treatment of this disease.

At the meeting of the general council of the University of Aberdeen on April 19th Professor Ashley W. Mackintosh, who has just resigned the chair of medicine, was appointed the general council's assessor to the Aberdeen University Court, in succession to the late Dr. John Scott Riddell. At the same time the council placed on record its appreciation of the work of Dr. Scott Riddell, who, besides being a distinguished surgeon, scholar, administrator, and writer, had taken a distinguished part in the life of the community.

Haddington Cottage Hospital.

The new cottage hospital at Haddington was opened on April 24th by the donor, Mr. John Vert of Pendleton, Oregon, U.S.A. Provost Andrew Phail, who presided, recalled that the scheme for the establishment of a cottage hospital at Haddington had been initiated at a meeting held in January, 1927, and the committee had thereafter appealed for a sum of £7,000, the estimated cost of a hospital to provide ten or twelve beds. A site had been offered by Mr. Henry Vetch of Caponflat, and Mr. Horsburgh, a native of East Lothian, now resident in the United States, had promised a subscription of £1,000. Thereupon Mr. John Vert, a native of the town of Haddington, who was now staying in the United States, had promised £7,000, provided that a like sum was raised for the endowment of the hospital. Having seen the plans of the proposed building, Mr. Vert had offered a further sum of £1,000, and his gift had ultimately been raised to a total of £10,000. A satisfactory response had also been made to the endowment fund, and it was expected that the running expenses of the hospital would be met in the ratio of one-third each from the endowment fund, payments by patients, and annual subscriptions; the chairman appealed to the public to do their part. Mr. Vert, in declaring the hospital open, expressed the hope that the institution would prove of lasting benefit to the district. The hospital is to be known as the Vert Memorial Cottage Hospital. It occupies a picturesque site on an eminence overlooking the town of Haddington and the valley of the Tyne, and has been built largely from material taken out of the neighbouring mansion house of Amisfield, which was recently demolished. It will contain two public wards of five beds each, two private wards, a maternity ward, and administrative quarters.

Edinburgh Hospital for Women and Children.

The annual meeting of the Edinburgh Hospital and Dispensary for Women and Children, and the Elsie Inglis Memorial Maternity Hospital, was held in Edinburgh on April 16th. The report showed that 659 patients had been treated in the Bruntsfield Hospital for Women and Children, and 923 in the Elsie Inglis Hospital. The ordinary income of the two institutions was £12,314 and the expenditure £14,328. Miss Gertrude Herzfeld, F.R.C.S., said that a supply of radium was urgently required by the Bruntsfield Hospital. A large grant of radium had been made to Edinburgh, but the whole of it had been devoted to the Royal Infirmary. The supply required by the hospital would cost about £2,000.

Ireland.

Public Health Administration in County Galway.

THE Minister for Local Government has advised the County Galway Board of Health that the appointment by the county council of Dr. E. O'Beirne as county medical officer of health from April 1st is an opportunity for correlating the executive control of the sanitary services with the arrangements for the treatment of tuberculosis in the county. For that purpose the Minister recommends that the board should appoint Dr. O'Beirne as chief tuberculosis officer. Having regard to the extent of the county and the comprehensive nature of the public health services, it is suggested that the board, instead of appointing a tuberculosis medical officer under Dr. O'Beirne,

should apply for authority to appoint an assistant county medical officer of health, who, in addition to duties under the tuberculosis scheme, would carry out work in connexion with school medical inspection and co-operate in the administration of the sanitary laws in the county health district. The usual remuneration for this position is at the rate of £550 per year, rising by increments to £650, with the usual travelling expenses. In the course of a long discussion it was stated that the county council appointed Dr. O'Beirne county medical officer of health, but made it a condition that he would carry out the duties of tuberculosis medical officer until after the health conference in June. Dr. O'Beirne said that the county council accepted his resignation as tuberculosis medical officer as from March 31st. After that date he could not accept responsibility for the services in the sanatorium, but he would assist as far as possible. If an epidemic occurred in Ballinasloe he could not possibly look after the tuberculosis scheme and carry out his duties as county medical officer of health. The matter was adjourned for a fortnight.

Promotion of Medical Dispensary Officers.

The Department of Local Government and Public Health has informed Kilkenny County Board of Health that it declines to sanction the transfer of Dr. J. A. Fitzgerald from Tiscoffin to Dysartmoon dispensary district, as he was appointed to Tiscoffin only last September. It points out that the intention of Section 5 of the Local Authorities (Officers and Employees) Act, 1926, is to enable the local authority to transfer officers with approved service to more desirable positions, and that it should operate in favour, other things being equal, of senior officers. The department desired to be informed why Dr. Ryan of Castlecomer, an officer of over eleven years' service, was passed over. It was decided to inform the department that Dr. Fitzgerald had several years' experience on Atlantic liners, and as he had successfully passed the examination of the appointments commissioners, the board requested sanction for his transfer.

Court Fees.

During the hearing of a recent action for damages against the Dublin United Tramways Co. before Judge Roche, K.C., evidence was given by Dr. E. P. Eustace, Dublin. On decree being given for £75, counsel for the plaintiffs asked for expenses, including expenses for the doctor. Counsel for the defendants held that the doctor's fee should be £1 11s. 6d. Mr. Justice Roche stated that the evidence of Dr. Eustace had been of great help to him and he would allow a fee of £3 3s., which he thought was little enough in the circumstances. On defendants' counsel repeating their contention the judge remarked that although this case did not come under the Workmen's Compensation Act, he would allow Dr. Eustace a fee of £3 3s. as he held he was entitled to it.

Correspondence.

ACUTE PERFORATION OF THE STOMACH AND DUODENUM.

SIR,—Mr. Graham Bryce's admirable critical review of the results of perforated gastric and duodenal ulcers (April 26th, p. 774) will have been read with interest by many of us who have had the opportunity of treating large numbers of these cases, and with his main conclusions most of us will be in substantial agreement, notably his opinion that the addition of a gastro-enterostomy to an operation for the closure of a perforation should be reserved for cases in which stenosis is present or likely to result from healing. This opinion is fortified by the fact that 32 per cent. of his patients remained quite free from stomach symptoms two years after suture without gastro-enterostomy. These results seem to me very striking and exceptionally good, and therefore to be accepted with caution as a guide for treatment.

An experience of close on 200 cases has brought me to conclusions similar to those formulated by Mr. Bryce, but the results of treatment differ considerably from his. My experience, based on following patients for a number of years, is that the great majority of cases of duodenal perforation treated by suture alone ultimately suffer from gastric symptoms, of varying severity it is true, but definitely due to stenosis or recurrence of ulceration or both. I would suggest that conclusions based on a two-year follow up are not a reliable guide. It may take years for stenosis to become effective. In one of my cases 13 years and in another 12 years, elapsed before the patients sought advice on account of symptoms due to stenosis. Another factor to be taken into account is the remarkable variation in the intensity of the symptoms provoked by duodenal ulcer, so that conclusions based on a temporary absence of symptoms are apt to be fallacious.

The claim is sometimes made that the reaction following perforation may lead to the healing of an ulcer. It may be so, but a scar with fibrosis remains and is prone to break down or to contract slowly till effective stenosis is produced. A further important factor is often forgotten—namely, that duodenal ulcer is often double and sometimes multiple. The anterior ulcer which perforates is in many cases accompanied by a symmetrical ulcer on the posterior wall which may, and often does, give rise to trouble later on.

The significance of the late results is really this: What influence, if any, should they have on the treatment carried out at the original operation for perforation; and, secondly, at what stage, if any, are patients treated by closure alone and free from symptoms also free from further danger, and are they good insurable risks? My own experience would lead me to say that while gastro-enterostomy is hardly ever necessary to assist immediate recovery in a case of perforation, patients who have been treated by closure alone should be regarded as likely to have further symptoms, at some time or other, and are probably never free from the possibility of such recurrence. From the point of view of life insurance they are bad risks.

On the other hand, cases in which gastro-enterostomy has been done along with closure of the perforation have given, in my hands, much better late results than those treated by closure alone. Lastly, cases submitted to a late gastro-enterostomy for stenosis and recurrence of ulceration have done extremely well. The legitimate conclusion seems to be that gastro-enterostomy may advantageously be added to the closure of a duodenal perforation if the operator is perfectly confident that it will in no way prejudice the immediate recovery of the patient. Otherwise, it should be deferred until demanded by symptoms later on, when it may be relied on to give relief.—I am, etc.,

Edinburgh, April 28th. J. W. STRUTHERS.

ETIOLOGY OF CYSTITIS.

SIR,—The following observations regarding the etiology of cystitis may be of interest to readers of the *Journal*.

1. Five groups of 12 young rats—6 males and 6 females—were fed on diets containing animal protein (casein) in amounts ranging from 0 to 80 per cent. of the whole diet; the diets were deficient in vitamins A and C, but contained a sufficiency of vitamin B, inorganic salts, and fats. Four of the rats died early in the course of the experiment and were excluded. At post-mortem examination of the remaining 56, cystitis *without accompanying urinary calculus* was found in 12—an incidence of 21.4 per cent. Of these cases, 8 were females and 4 males; the condition being thus twice as common in the female sex. Its distribution among the five groups was as follows:

	No. of Animals receiving diet.	Incidence of Cystitis.	
		Males.	Females.
Animal Protein in Diet:			
0 per cent.	11	0	0
20 „	12	1	1
40 „	11	0	4
60 „	12	1	1
80 „	10	2	2
Total	56	4	8

Cystitis was therefore significantly commoner in animals whose diet contained 40 per cent. or more of animal protein.

2. In a second series of 60 rats, fed on the same diets but in which vitamin A was provided as cod-liver oil, no cystitis occurred.

Hitherto in my work on the experimental production of urinary calculus I have encountered cystitis frequently, but almost always in association with stone in the bladder. Occasionally stone has been found without cystitis; but never, in an experience which amounts to well over 200 cases of experimentally produced urinary calculus in rats, have I so consistently encountered cystitis without stone.

It seems likely, therefore, that diets rich in animal protein and poor in vitamins A and C provide conditions favourable to the genesis of cystitis. I emphasize the importance of vitamin C, having observed some ten years ago[1] that congestion of the vesical mucous membrane—a condition known to predispose to cystitis—may be an early manifestation of deficiency of this vitamin.

In view of these observations I venture to predict that in the treatment of cystitis the exclusion of animal protein from, and the provision of an abundance of vitamins in, the diet of sufferers are likely to be attended with beneficial results.—I am, etc.,

R. MCCARRISON,
Colonel I.M.S.

Pasteur Institute, Coonoor, South India, March 27th.

OVARIAN CYST OR ASCITES.

SIR,—It will be agreed, I think, that the differential diagnosis between an ovarian cyst and ascites is not always easy. I should like to draw attention to a physical sign which is obtainable in a case of ovarian cyst, and which I have found to be very useful and reliable.

In the type of case to which I refer the signs on which one usually relies are masked or absent. For instance, the abdomen is much enlarged, but the shape may not be typical of either condition. The shifting dullness of movable fluid is not obtainable. One or both flanks are dull on percussion, and there is no resonance in front, except in the epigastrium. There is a fluid thrill over the greater part of the abdomen. The diagnosis lies between a large collection of free fluid and a large, slack ovarian cyst. Such cases are not very uncommon.

To elicit the sign, the fingers of the two hands are pressed—one hand on either side of the lower abdomen—firmly and steadily backwards towards the lumbar spine. In the case of an ovarian cyst the pulsation of the abdominal aorta can be felt. Presumably the tension in the cyst, caused by the pressure of the fingers, permits the transmission of the pulsation. This sign can be accentuated—and also be made evident to onlookers—by inserting one end of a flat ruler (or a long pencil) under the fingers of one of the hands pressing on the abdomen. The free end of the ruler will then show the pulsation magnified.

I have never been able to obtain this sign in a case of pure ascites.—I am, etc.,

A. J BLAXLAND.

Norwich, April 26th.

THE TEPID BATH IN THE TREATMENT OF MEASLES.

SIR,—Dr. Vipont Brown's account of the life-saving bath in his case of measles with hyperpyrexia (*Journal*, April 19th, page 739) and the consequent disapearance of the rash raises the question of bathing as a routine and prophylactic measure. Twenty-five years ago my children had measles during an epidemic of a severe type. From the onset until the temperature became normal I had them bathed twice daily—some common salt and soda being added to the water, the temperature of which was just over 100° F. I was encouraged by the results to adopt this treatment—in the teeth of much opposition when most parents thought that a child with measles should not be washed at all. I have never seen anything but increased comfort to the patient, and a rapid appearance—and disappearance—of the rash and high temperature.

Incidentally, I do not insist on the bedpan in those children who cannot use it satisfactorily; there is less fatigue and a better evacuation in the normal posture. The routine toilet of the ears, eyes, and throat includes for the ears the use of peroxide, and, if there is debris, syringing with isotonic saline; protargol 2 per cent. and castor oil for the eyes; and glycothymolin and salt gargles three times a day. Eye-shades are worn, and no reading is allowed. All these precautionary measures are continued from the beginning of the illness until the temperature is normal. Sunlight and air in plenty are admitted to the room, which is kept at a temperature of 60° F.

I have just had 35 cases in a boarding school for the daughters of educated parents. I was fortunate enough in having no broncho-pneumonia, and no eye or ear trouble, and, perhaps, more fortunate still in having only one parent objecting to the baths; this parent, curiously enough, had a child at another school, where more conservative methods were adopted, the measles being followed by mastoid infection and broncho-pneumonia.

One of my middle-aged nurses said: "They seem to get well very quickly with your new bathing treatment." Is it new? I hope, and think, not.—I am, etc.,

H. ANGELL LANE, M.R.C.S., D.P.H.

Battle, April 19th.

[1] *Indian Journ. Med. Research*, 1919, vol. vii, p. 279.

TREATMENT OF GASTRIC AND DUODENAL ULCER.

SIR,—I have read with much interest in the *Journal* of April 19th the excellent lecture by Dr. Charles Bolton. I think its value would have been much enhanced if he had followed up his former work on causation, and differentiated between gastric and duodenal ulcers and the better known hyperchlorhydria. I dealt with this subject in an address in 1925, which I am afraid is now out of print; however, I wish to make the following supplementary remarks, which he can accept for what he considers their value.

The symptoms of hyperchlorhydria and duodenal ulcer are much the same, though I think in the former the vagotonia is much less. It is well to have some sign to indicate when an ulcer has occurred, and the sign on which I place a considerable amount of reliance is the presence of peptone in the urine. If one takes a little urine passed an hour or two after a meal and floats it on the top of Fehling's solution in a test tube, the presence of a pink ring at the junction of the two fluids indicates peptone. If there be any serum-albumin in the urine, which is the exception rather than the rule in these cases, a reddish-brown ring forms, which can scarcely be confounded with that of peptone. Moreover, serum-albumin, globulin, and albumose are precipitated by picric acid, but not so the peptone of which I am speaking. Some will say that it is not peptone but albumose, and that it is of no clinical importance, as it has been found in scarlet fever, measles, pneumonia, empyema, advanced phthisis, acute yellow atrophy of the liver, and phosphorus poisoning. I think any medical man can discriminate between these diseases and duodenal ulcer. It really does not matter what chemists call it so long as it acts as an indicator of intestinal ulceration. The position of the ulcer can be determined by the symptoms.

Whether the case be one of hyperchlorhydria or duodenal ulcer always order night and morning one or two glasses of hot water, followed by concussion of the fifth and second dorsal spines, and often also of the seventh cervical spine when the stomach is not emptying itself quickly. After the seance at bedtime the patient gets one or two tablespoonfuls of olive oil. Sodium bicarbonate neutralizes the acid, but its value is lessened by the fact that it stimulates the further production of hydrochloric acid; chalk is a better antacid. Sodium chloride should only be allowed in small quantities. To stimulate the healing of the ulcer, if such exists, I often order the iodide of calcium with the syrup of the hypophosphate of calcium; one-tenth of a grain of parathyroid night and morning is also useful. To make the hyperacidity more or less harmless kaolin is beneficial. It is well not to use the laxative kaolin, as phenolphthalein in the urine gives a pink ring with Fehling's solution. For a laxative, the old white mixture is about the best and paraffin the worst.—I am, etc.,

JAMES BURR.

Hindhead, April 22nd.

HARE-LIP AND ITS TREATMENT.

SIR,—As one intensely interested in this subject, may I be allowed to comment upon a few points in Mr. Gilbert Warburton's article in your issue of April 19th (p. 732)?

Mr. Warburton fails to stress the prime importance of obtaining sound muscle union; indeed, his description might easily be misinterpreted as indicating a closure in two layers, skin and mucous membrane, though the muscle layer is included, no doubt, in his silkworm-gut sutures, "passed deeply into both sides." Buried catgut sutures for muscle approximation occasionally become infected and work out through, and to the detriment of, the skin suture line. For some time I have employed with satisfaction the end-on or vertical mattress suture introduced from the mucosal aspect of the lip and taking up, in its outer loop, a good bite of the muscle. This relieves the skin sutures of any duties other than that of skin approximation and so tends towards the production of a better skin scar.

Anaesthesia for these cases should be provided by some means which keeps the anaesthetist and his apparatus as clear of the surgical field as is possible; which maintains a perfectly clear airway throughout the operation and prevents with certainty the inspiration of blood through the glottis; and which distorts the parts under treatment as little as possible. The single soft tube intratracheal method, introduced by Magill and capable of application to even the smallest infant, seems to me to be ideal, and has rendered my own operations completely free from anaesthetic and post-anaesthetic anxieties. It provides the additional advantage of carrying away from the operator's face the anaesthetic-laden expirations, while it allows of maintenance of anaesthesia at a particularly light level, with a corresponding rapid return of all reflexes at the end of the operation.

Extensive separation of soft tissues from bone, with its concomitant disturbance of muscle attachments, should not be necessary if the bony parts are moulded into reasonably good position. It is just as important to mould the premaxilla of the unilateral complete cleft into correct alignment as it is to deal with the more obviously displaced premaxilla of the bilateral complete cleft, and, in this connexion, there is much to be said in favour of the preliminary alveolar wiring practised by many American surgeons.

In a smaller series of cases, I have been impressed, as has Mr. Warburton, by the frequency with which the condition has been attributed to pre-natal impressions or accidents, almost invariably timed within the first eight to ten weeks of the pregnancy. I am similarly driven to the conclusion, in spite of personal scepticism, that this connexion represents something more than coincidence.—I am, etc.,

London, W.1, April 23rd. T. POMFRET KILNER.

ANTIMALARIA MEASURES.

SIR,—Sir Malcolm Watson, who is at present away from England, will doubtless reply to Lieut.-Colonel C. A. Gill's letter (April 12th, p. 718), but there are certain parts of it on which I would wish to comment.

Colonel Gill seems to suggest that malariologists are wrong in assuming that they have the key to the solution of the malaria problem in the discovery of the role of the mosquito in the transmission of the malaria parasite. It may, however, be asserted absolutely that this discovery does provide the key, and, although the role of the mosquito was demonstrated thirty years ago, this key may still be of value if properly used.

If the malariologist thinks with Colonel Gill that the "difficulties, administrative and financial," are insuperable, there does not seem much hope of preventing malaria; but if he has the courage and persistence which were so characteristic of Manson and Gorgas, and still are, I am glad to say, of Sir Ronald Ross and Sir Malcolm Watson, perhaps these great difficulties will not be found to be "insuperable." The difficulty is not so much administrative or financial as it is to find the man who can persuade the administrator that mosquito reduction is possible, that it can be done without great cost, and that the expenditure gives a most lucrative return. Although in certain areas all mosquitos can be destroyed, the so-called old school does not ask more than that the number of certain kinds of anophelines shall be kept under control in certain limited areas; and if this view is presented to the administrator he will, whether government or private, in my experience, get over the financial difficulty and ask for further advice when he finds that he has achieved an economy.

It is not said by the so-called old school that "social and economic conditions are of no importance," but they think that improvements of a social, economic, educational, medical, and public health character will take some time to act, and that they will come quickly when mosquito prevention has taken place.

In one case in Singapore there was much malaria in a street whose inhabitants were a respectable class of Chinese, and though the social, economical, and educational character was fairly good, the disease in the street was not prevented until some seepage water in the grounds of Government House just behind this street was put below the surface.

Perhaps one of the most important things that Sir Malcolm Watson has demonstrated is that, before work in malaria prevention is commenced, study of the kind of anopheline present must be made and its habits known. If measures which would eradicate the anophelines which come from a lowland swamp are adopted for a ravine-stream breeder failure will result. The measures to be adopted must vary with the species found.

But perhaps the most serious statement in Colonel Gill's letter is "that the old school have endeavoured to establish their viewpoint by means of unsubstantiated claims regarding their successes." How unsubstantiated? Has Colonel Gill not heard of the Panama, or of the saving of Port Swettenham as a port? Are the claims to these successes unsubstantiated? All through the Malay Peninsula there are examples of success, not only those of Sir Malcolm Watson, though his methods have been used. Many health officers and private practitioners have reduced the amount of malaria by mosquito reduction in several towns and many estates, and there must be some hundreds of rubber estates in Malaya which have found mosquito reduction to have been a financial economy. A notable case is the Gunong Pulai dam near Singapore. This is in an area which those who had had experience knew would teem with *A. maculatus* as soon as the jungle was opened. Anti-malaria work was carried out with such success that there was practically no fever. A hospital provided in anticipation for thirty beds never had more than three patients, and the health of the coolies was so good that it was possible to reduce their wages, with resultant large economies.

It has been demonstrated over and over again that expenditure on mosquito eradication, and even reduction, when properly carried out has resulted in better health, and therefore in the greater economic value of the population.

Colonel Gill has put up a "logically illogical position," but I think that logically his position is unsound and that his views rather than those of Sir Malcolm Watson will do harm to the health and welfare of the Empire.—I am, etc.,

J. TERTIUS CLARKE,
Harrow, April 22nd. Late Medical and Health Officer, Perak.

QUININE IN ALBUMINURIA.

SIR,—I had a male patient under my care in Teheran, similar to the case described by Dr. Hewetson in the *Journal* of April 19th (p. 761).

The diagnosis was chronic nephritis ("large white kidney"), and many methods of treatment were tried without effect. Finally, as he had a moderately large spleen, quinine in large doses was given. The quantity of urine rose at once from under 500 c.cm. to 1,000, 1,500, and 1,700 c.cm. The oedema disappeared and the man left hospital shortly afterwards with only a faint trace of albumin and a rare cast. He was afebrile throughout his stay, and his blood picture was that of a simple anaemia with no haematozoa.

I never knew quinine, given by whatever route or in whatever dose, to cause premature emptying of the uterus,

but I saw not a few pregnant women die of malaria who had abstained from taking it. Indeed, I took to issuing a warning in the public press at the start of every malaria season.—I am, etc.,

London, N.W.1, April 22nd. A. R. NELIGAN, M.D.

DOSE OF MERCUROCHROME BY THE MOUTH.

SIR,—In the *Journal* of April 19th (p. 761) Mr. W. H. Martindale asks medical men to communicate the results they have obtained from the oral administration of mercurochrome. He also asks for information concerning the dose employed.

I have been using mercurochrome put up in 100 milligram capsules for the last six months, and have given as many as three, three times a day—that is to say, a total daily dosage of 900 milligrams. As a rule, however, I do not go beyond 600 milligrams, and with this dose have never noted any toxic effects. The stools are deeply stained, and the urine becomes rose-coloured and bacteriostatic.

It is always a difficult matter to assess the value of urinary antiseptics, and, although I am favourably impressed with the drug, I am not yet in a position to give detailed information concerning its efficiency.—I am, etc.,

London, W.1, April 25th. KENNETH WALKER.

STERILITY IN WOMAN.

SIR,—Mr. Leith Murray's letter (April 26th, p. 798) referring to Professor Blair Bell's address on female sterility raises several important points. Particularly in the hospital class, there is a definite risk of domestic disaster in the small percentage of cases where, owing to the proved occlusion of tubes or the entire absence of spermatozoa, the doctor can hold out no hope of conception. In their own words, it is the "fault" of one or other partner. The very word "fault," after probably many years of hopeful expectation and disappointment, has a harmful psychological effect. In such cases I always avoid the suspicion of arrogant omniscience, and point out that in many cases the doctor has proved to be wrong, and that hope should not be entirely banished. I have never come across cases of threatened suicide such as Mr. Leith Murray's, but I can easily understand them. I do not think that any difference should be made between private and hospital practice in strongly recommending examination of the semen before subjecting any woman to treatment.

Mr. Leith Murray's figures concerning the negative results of insufflation agree with my own rather than those of Professor Blair Bell. In the absence of palpable abnormality, I can remember only two cases in a long series where the tubes were found to be occluded. I, also, flood the vagina with saline in order to eliminate the possibility of unnoticed leakage, as abdominal auscultation is an uncertain test. The question of curettage in this connexion is important. In most cases I am convinced that a careful dilatation is the important factor, and I confine myself to a light stroke of a sharp curette, anteriorly and posteriorly, to eliminate the possibility of gross thickening of the endometrium, which is rare. The drastic removal of a healthy endometrium, which is often undertaken, appears to me quite purposeless, and leads to those cases, not very rare, where the patient continues to be sterile, but now has a leucorrhoea, constant, slight, but very annoying.

I hope that Professor Blair Bell will reply to Mr. Leith Murray's query as to why he recommends operation for primary retroversion rather than the use of a Hodge pessary. In my hands the latter has been generally futile, except in cases of subinvolutional retroversion. Where all other measures have failed I have used the old Alexander-Adams operation in several cases, pregnancy resulting in a satisfactory proportion.—I am, etc.,

JOHN S. M. CONNELL.

April 27th. Honorary Gynaecologist, Midland Hospital, Birmingham; Visiting Gynaecologist and Obstetrician, Hollen Hospital.

ETIOLOGY OF DENTAL CARIES.

SIR,—I am glad that Professor Mellanby is able to confirm the conclusions derived from Mrs. May Mellanby's experiment—namely, that vitamin D or ultra-violet irradiation is essential for good bone and tooth calcification, for the protection of the abraded or carious tooth by arrest of caries, and the protection of the pulp by secondary dentine. But the problem is how to reconcile these conclusions with other important observations. It is not obvious that more completely calcified enamel will resist caries better, enamel caries being due to the solution of the calcium in the acid which results from the fermentation of stagnant carbohydrate; and no one has yet found a tooth so impregnably calcified that it can resist artificial caries *in vitro*. Neither is it obvious that numerous interglobular spaces in defective dentine would seriously accelerate the carious process in an uncleansed carious cavity. Secondary dentine protects the pulp from infection, no doubt; but it does not protect the tooth against caries. Nor has anyone yet proved that the recalcification of dentine which takes place in arrested caries is the cause of the arrest. It may be a result of arrest. It is also a much rarer phenomenon than is the production of secondary dentine.

Dr. E. W. Fish has produced cogent evidence that the block of dentine which lies between the carious cavity or abraded surface and the pulp is incapable of any vital reaction, and that in its recalcification, when this occurs, it plays as passive a part as a denture which becomes, in certain circumstances, coated with a dense muco-calcareous deposit. We have to suppose, therefore, that other influences making for the defence of the teeth are closely associated with the calcification-promoting factor in vitamin D. I find that a body bath of ultra-violet light rapidly removes the extreme sensitiveness associated with active cervical caries. These observations surely point to the conclusion that irradiated ergosterol promotes some other function in addition to that which produces calcification.—I am, etc.,

F. TALBOT,
London, W.1, April 22nd. L.D.S., M.R.C.S., L.R.C.P.

AMPUTATIONS AND ARTIFICIAL LIMBS.

SIR,—Your report of the discussion on the above subject at the Section of Surgery of the Royal Society of Medicine is exceptionally interesting, especially to those who recognize the value of the opinions of Mr. Muirhead Little in his book on amputations and of the surgeons at Roehampton who have enjoyed such opportunities of noting the after-results of thousands of amputations. Artificial limb makers will especially welcome an opportunity of noting the effect of amputations in war cases and comparing them with similar operations in civilian cases. This applies with emphasis to the point raised as to the value of Syme amputations, and the Stokes-Gritti and other operations through the knee or ankle joints. It was probably impossible for the surgeons to give definite statistics as to the number of these cases which required reamputation during the succeeding ten years, but in civilian cases the problem is very different.

In war cases the Syme amputations were largely due to gangrene from frost-bite, and in the knee-joint amputations there were complications from sepsis. Added to this, the original amputations were often hurried, involving subsequent operations. In civilian cases, on the other hand, practically the only complication to be dreaded is in cases of tuberculosis, and at the present day the trouble is generally eradicated in the amputation. Thus we find in our records as artificial limb makers of very wide and long experience that, taking a hundred cases of Syme amputation, not a single case had to undergo reamputation, and the wearers of the limbs can undertake arduous duties—on railways, at the docks, in building operations, etc.—and continue to wear the limbs for ten, twenty, or more years without any difficulty.

With reference to the amputations at the knee-joint providing an end-bearing stump, the same experience has been obtained, and the power to take pressure on the extremity encourages the wearer to engage in tasks which involve long periods of walking or standing. In all these

cases we consider it essential that the stump shall fit snugly in the socket at the extremity, as in limbs which permit of a loose movement of the stump, either in the socket or on the end-bearing, there would be danger of trouble from resultant friction. We consider that, even in the war cases, some of the trouble has been from imperfectly fitted limbs or from alteration in the stump after the artificial limb is applied, and that the number of these cases is now very small.

In conclusion, we must endorse the opinion that the co-operation and advice of the operating surgeon is of the very highest value to the limb maker, and that it is by consultation together that the most perfect results are attained.—We are, etc.,

London, W.C., April 26th. W. R. GROSSMITH LTD.

TESTS FOR COLOUR VISION.

SIR,—The centenary of Hickman again draws attention to the fact that there is no means in this country by which a man who has made a scientific discovery can establish his facts. Men who consider themselves authorities say of an unknown worker, "Who is he to tell us we are wrong?" and refuse to examine the facts.

When I took up the subjects of vision and colour vision over forty years ago I found a mass of misstatements in the textbooks. Having been appointed on the International Code of Signals Committee of the Board of Trade to advise on a test for colour-blindness I read a paper embodying a large number of new facts before the Royal Society. Criticism was almost confined to my statement that the wool test was very defective; as a matter of fact it allows 50 per cent. of dangerously colour-blind to escape detection, and of those rejected by it about 50 per cent. are practically normal sighted. The Royal Society then wrote to the Board of Trade offering to appoint a committee to decide on the best test for colour-blindness. After three years they recommended the wool test, and I lost my position at the Board of Trade. I could then obtain no proper hearing until Devereux Marshall took up the question in the *British Medical Journal*, and a committee of the Ophthalmological Society agreed with me. The Royal Society still remained unconvinced and refused to examine the facts; but I have to thank the Board of Trade for its honourable behaviour in this matter. I was appointed special examiner in 1920.—I am, etc.,

Board of Trade, S.W., April 21st. F. W. EDRIDGE-GREEN.

The Services.

NAVAL MEDICAL COMPASSIONATE FUND.

A QUARTERLY meeting of the directors of the Naval Medical Compassionate Fund was held on April 24th, when Surgeon Rear-Admiral Arthur Gaskell, C.B., O.B.E., K.H.S., Medical Director-General of the Navy, was in the chair. The sum of £180 was distributed among the several applicants.

THE GILBERT BLANE MEDAL.

IN announcing the award of the Gilbert Blane Medal to Surgeon Commander J. F. H. Gaussen, R.N., on April 12th, it should have been stated that the medal is awarded annually to the medical officer who obtains the highest aggregate marks at the examination for promotion to the rank of surgeon commander.

DEATHS IN THE SERVICES.

Brevet-Colonel John Francis Bateson, late of the R.A.M.C. and of the Coldstream Guards, died at the Manor House, Great Chevercsty, Devizes, on April 12th, aged 71. He was born at Liscard, Chester, on February 17th, 1859, and was educated at Harrow and at Edinburgh University, where he was in the Rugby fifteen, and graduated as M.B. and C.M. in 1881. He also took the M.R.C.S. in 1884. Entering the Army as surgeon in 1885, he was seconded for service with the Egyptian Army from 1893 to 1895, was transferred to the Coldstream Guards as surgeon major in 1900, became surgeon lieutenant-colonel in 1905, and retired in 1913. He served throughout the South African war, 1899–1902, when he took part in operations in Natal, including the actions at Elandslaagte, Reitfontein, Lombard's Kop, and Laing's Nek, and the defence of Ladysmith; in the Transvaal, including actions at Belfast and Lydenberg; and in Cape Colony; was mentioned in dispatches in the *London Gazette* of February 8th, 1901, and July 29th, 1902, and received the Queen's medal with six clasps, and the King's medal with two clasps. He also rejoined for service in the war of 1914-18.

Obituary.

FREDERICK EDWARD WYNNE, M.B., CH.B., D.P.H.,

Medical Officer of Health for Sheffield, and Professor of Public Health in the University of Sheffield.

BY the death of Dr. Frederick Edward Wynne the medical profession loses a man of great ability and outstanding personality. An Irishman by birth, he was the son of the Bishop of Killaloe. He was educated at Trinity College, Dublin, and took the degrees of B.A., M.B., Ch.B., and B.A.O. in 1894. After a short assistancy in the Midlands, he settled in Leigh, Lancashire, in 1896, and remained in general practice in that town until September, 1909, when he was appointed the first full-time medical officer of health for the borough of Leigh.

Photo Lafayette, Manchester.

He took his D.P.H. at the University of Manchester in 1910. In December, 1911, he was appointed medical officer of health for Wigan. From 1914 to 1917 he held a temporary commission as captain in the R.A.M.C., and saw service in Egypt and Palestine. On leaving the Army he returned to Wigan, and remained there until 1921, when he was appointed medical officer of health for the city of Sheffield and professor of public health in the University. Both these appointments he held at the time of his death.

Professor Wynne was a man not only eminent in his professional capacity, but of wide sympathies and varied interests. He was a writer of distinction, both on medical and on general subjects. Apart from his contributions to the purely medical press, he was for many years a correspondent on medical subjects to the *Manchester Guardian*. He was also a contributor of many non-medical articles to that newspaper, these being in the nature of essays on various aspects of Lancashire life which came under his observation, and which were written with great charm and sympathy. He also wrote several novels. In 1908, during Miss Horniman's tenure of the Gaiety Theatre, Manchester, he had a play produced at that theatre entitled *Subsidence*, which dealt with certain aspects of the destruction of surface property through the subsidence of the land beneath it caused by mining. Outwardly somewhat reserved, he showed to his intimates great charm of manner, kindliness of disposition, and a high standard of integrity. He was a widely read man and a good classical scholar. Impatient of anything in the nature of a sham or of vulgar pretence, which offended his somewhat critical and fastidious temperament, he was able to express himself with an asperity to which his literary style gave an edge. His writings were invariably drawn from subjects which came within the field of his own observation and experience. His was not an imagination that could create worlds of its own; but he could write about the world he knew with rare sympathy and discrimination. *Fortune's Fool* is the story of a young man of high ideals and ambitions, dragged by a drunken wife through the slough of club practice and sixpenny work to final tragedy. In it he deals with some of the most unfavourable aspects of medical practice (largely abolished through the coming of the National Insurance Act) with exceptional vividness. His play *Subsidence* drew a fine picture of an outwardly unsympathetic type—an elderly Lancashire farmer who clings to his farm, where his father and grandfather had worked before him, though he is warned of its inevitable ruin through the workings of the colliery beneath his land, and comes to his death in the waters of the local "flash"—a term used for rapidly spreading surface water due to colliery subsidence. In *A Mediterranean Mystery* he drew on his army experiences; and his impatience of shams was shown in his last novel, *Digby's Miracle*, the story of a

young medical man who is tempted by the prospect of money into the production of a sham miracle in connexion with a supposed holy well, and his subsequent repentance. Besides being a writer, he was a lecturer of great distinction and charm, and his lectures were marked by the same quality as his writings.

For many years Professor Wynne took an active part in the affairs of the British Medical Association, and served both Divisions and Branches in various capacities. He was a member of the Executive of the Leigh Division, 1907–8, and representative of the Division in the Representative Body, 1905–6 and 1909–12. He was a member of the Lancashire and Cheshire Branch Council, 1909–14, member of the Executive Committee of the Wigan Division, 1912–14, honorary secretary, Wigan Division, 1913–14, and member of the Executive Committee of the Sheffield Division, 1922–28. He also served on the Public Health Committee of the Association for five years, and on its Superannuation Subcommittee in 1923–24. At the Annual Meeting of the Association in Portsmouth in 1923 he held office as vice-president of the Section of Public Health, and at the Manchester Meeting last summer he opened the discussion on health propaganda, from the administrative point of view, in the Section of Medical Sociology.

He was not 60 years of age at the date of his death, which occurred after a short illness; and the news must have come as both a shock and a surprise to many of his friends. He leaves a widow and three sons. The eldest son is in the Air Force, the second is in the Navy, and the third in the Army. His many friends will feel their lives the poorer for his departure.

J. S. M.

A Sheffield colleague writes: Dr. Wynne had made a deep impression on the City of Sheffield and its health services. He was greatly interested in the prevention of overcrowding, and gave his strong support to the re-housing schemes which the corporation has been carrying through for some time. He was a man of outstanding ability and original thought, and did not hesitate on occasions to express views which he knew might not meet with general acceptance. He was for many years president of the Irish Medical Society, and it was a delight to listen to his able speeches at their annual dinner on St. Patrick's Day. Dr. Wynne was the soul of geniality and kindness, and his loss will be deplored by all who knew him.

SEAGHAN P. MacENRI, M.D.,

Professor of Ophthalmology and Otology, University College, Galway.

DR. SEAGHAN P. MACENRI died recently at his residence at Taylor's Hill, Galway. He was born in co. Sligo sixty-eight years ago, and was educated at Trinity College, Dublin, and St. Vincent's Hospital, Dublin, graduating M.B. in 1886, and proceeding M.D. in 1888. For a period he lived in London, where he was ophthalmic surgeon to the Italian Hospital, to the London School Board, and to the London County Council schools; medical officer for out-patients, Miller General Hospital, Greenwich; physician to St. Mary's Orphanage, Blackheath; surgeon to the London Metropolitan Police; and clinical assistant to the Royal Westminster Ophthalmic Hospital and the Royal Ear Hospital, London.

Dr. MacEnri gave up his large practice in London (where he was better known as John Patrick Henry) to return to Ireland and throw himself into the Irish Ireland movement. For a time he was head professor at the Leinster School of Irish, and afterwards head professor at Connacht College, Spiddal, in the foundation of which he played a prominent part. University College, Galway, had the benefit of his experience and profound knowledge in two spheres, for he filled the posts of professor of ophthalmology and otology and also of lecturer in modern Irish. He was a member of the governing body of the College and of the Senate of the National University of Ireland. A fine linguistic scholar, he was the author of several popular manuals for Irish students, including "An Modh Direach," "An Réalt Eolais," "Udhacht an Stiocaire," "Bás Ghofraidha Uí Dhomhnaill," and "A Handbook of Modern Irish," all of which were most helpful to students acquiring a knowledge of Irish. He also edited the works of the late Michael Breathnach. Because of his impartiality and his dissociation from politics, he was elected president of the Gaelic League some years ago, but was unable to continue in that position owing to the strain of various other duties. In 1917 he married Jane Louisa Little, who survives him with one son and two daughters.

FRANCIS L. A. GREAVES, O.B.E., F.R.C.S.,

Senior Honorary Surgeon and Honorary Surgeon Ear, Throat, and Nose Department, Derbyshire Royal Infirmary.

THE news of the sudden death, on April 16th, of Mr. Frank Greaves at the age of 55, came as a shock to a wide circle of friends and medical colleagues. He had tried recently to curtail some of his professional activities on account of his health, but he was actively engaged in hospital and consulting practice until a few weeks ago, when he went away for a rest and holiday.

Francis Ley Augustus Greaves was born at Derby on July 4th, 1874. The son of a medical man, Dr. C. A. Greaves, who held the post of honorary physician to the Derbyshire Royal Infirmary, Frank Greaves entered St. Thomas's Hospital, where, after a distinguished career as a medical student, he obtained the diploma M.R.C.S., L.R.C.P. in 1897, and was appointed house surgeon. In 1898 he became assistant house-surgeon, and in the following year house-surgeon, to the Derbyshire Royal Infirmary, which institution he was still serving at the time of his death. In 1902 he obtained the diploma F.R.C.S.Eng., and the same year was appointed honorary surgeon to the Royal Infirmary. Three years later he inaugurated the ear, throat, and nose department, acting as honorary surgeon in this specialty and also as honorary surgeon in the general surgical departments. As an officer in the Territorial Force, he went on active service at the outset of the war; and later his surgical abilities were fully employed as acting lieutenant-colonel in charge of surgical divisions of the 26th and 74th General Hospitals in France, for which services he was awarded the O.B.E. (Military Class) on demobilization. Apart from his work at the Derbyshire Royal Infirmary, Greaves held the following honorary posts in the district: consulting aural surgeon to the Derbyshire Hospital for Sick Children; consulting surgeon to the Whitworth Hospital, Darley Dale, and to the Ripley Cottage Hospital.

He had a large consulting practice, both as a throat specialist and in general surgery, for more than twenty years, and was held in the highest esteem by the profession in and around Derby. His hospital work was of a very high standard; his outstanding experience being in the surgery of the thyroid gland and the treatment of fractures. He was always an enthusiastic worker for the Derby Medical Society, and his life and work did much for the scientific side of medicine. He was a warm supporter of the British Medical Association, and was vice-president of the Section of Surgery at the Annual Meeting at Nottingham in 1926. When he died he had just finished a year in office as chairman of the Derbyshire Division. He contributed articles to the *British Medical Journal* on surgical subjects.

In 1906 he married Constance May Rice, who, with their son, survives him.

JOHN GARDNER, M.R.C.S., L.R.C.P.,

Consulting Surgeon, Montagu Hospital, Mexborough.

We regret to record the death of Dr. John Gardner, which took place suddenly from cardiac embolism, on April 16th, at his home near Hartley Wintney, to which he had retired after relinquishing his practice at Sutton Valence. He was born at Bolton-le-Sands, Lancashire, on May 17th, 1867, and was educated at the Friends School, Lancaster. After becoming a member of the Pharmaceutical Society he took up the study of medicine, first at the Sheffield Medical School, where he was a student under Dr. Christopher Addison, and then at University College Hospital, London. After obtaining the diplomas M.R.C.S., L.R.C.P. in 1899 he began practice at Bolton-on-Dearne, Yorks, but shortly joined a partnership in the neighbouring town of Mexborough, where for upwards of twenty years he led a most strenuous life in a busy colliery district, being surgeon to the Montagu Hospital and the Great Northern Railway Company; he took a special interest in the work of the St. John Ambulance Brigade. The strain of the war years, when he was called upon to undertake a large amount of the operative work at the hospital in addition to his large practice, began to tell on his health, and he showed signs of myocardial degeneration. He was advised to give up his work in Mexborough and to seek a sphere less laborious. So much was his work at the hospital appreciated by his colleagues and the Hospital Committee that he was elected consulting surgeon to the hospital, and presented with a scroll recording the honour when he retired from the staff. After a year's rest he resumed practice at Sutton Valence, near Maidstone, and was appointed medical officer to the public school there. Here again his ability made him a very popular country practitioner, with the inevitable result of hard work, and a final breakdown in health; he was compelled to retire from practice two years ago after an attack of coronary embolism.

John Gardner was of the best type of general practitioner—conscientious, painstaking, thoroughly sound in his work, modest, kindly, and sympathetic. He was beloved by all who knew him, and his patients were his friends. In each of the places where he was in practice he identified himself with the local social life. Possessed of a good bass voice he was always willing to help at local concerts and festivals, and sang in the church choirs. He was president of the Mexborough Choral Society, and it gave him great pleasure to take part in the various musical festivals which are a feature of the Yorkshire choral societies. He was for several years churchwarden at Mexborough.

At the funeral service, on Easter Monday, at Sutton Valence, the church was filled with between two and three hundred of his patients and friends, who had come, some from Yorkshire, to pay their last tribute. He leaves a widow and two daughters. Two of his brothers are in the medical profession—Dr. T. H. Gardner, chairman of the Wandsworth Division, and Dr. H. Gardner, honorary radiologist to the Wilson Hospital, Mitcham.

We regret to record the death, in his seventy-fourth year, of Dr. JOHN MACKINNON, which took place at the Broadford Hospital, Isle of Skye, on April 18th, following a motor accident. John MacKinnon received his medical education in Edinburgh, where he graduated M.B., C.M. in 1894, and won the medal in anatomy. After spending two years as an assistant in a Yorkshire practice, he went to South Africa, where he remained till 1915. He had an extensive practice in Somerset East, Cape Colony, and the surrounding district. During the Boer war he placed his professional services at the disposal of the British authorities, and was present at several skirmishes. In the great war he became a captain in the R.A.M.C., and saw service in Malta, Palestine, and Egypt from 1915 to the end of the war. Afterwards he retired to his native Isle of Skye, where he practised in the parish of Strath. He is survived by a widow, a son, and a daughter.

The following well-known foreign medical men have recently died: Dr. VARIOT, an eminent Paris paediatrist and honorary senior physician to the Hôpital des Enfants Assistés; Dr. RAPP, honorary professor of medicine at the faculties of Lyons, Geneva, and Strasbourg, and corresponding member of the Académie de Médecine; Dr. HENRI BRIN, professor of clinical surgery at the Angers School of Medicine; Dr. FRIEDRICH ROLLY, emeritus professor of special pathology and treatment, and director of the medical polyclinic at Leipzig University, aged 56; Dr. THOMA TOMESCO, professor of pathology and therapeutics at Bucarest; Dr. WALTHER FELIX, professor of anatomy and director of the anatomical institute at Zurich, aged 70; Professor LENDRICH, a hygienist of Hamburg; Dr. RICHARD MILLS PEARCE, general director of the division of medical education of the Rockefeller Institute since 1920, aged 55, of heart disease; and Dr. LAURENCE KINSMAN MCCAFFERTY, a prominent New York dermatologist, aged 39.

Universities and Colleges.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examination indicated:

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—C. J. C. Earl (*with special knowledge of Mental Deficiency*), B. Sennock (*with special knowledge of Psychiatry*).

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary quarterly comitia of the Royal College of Physicians of London was held on April 24th, when Sir John Rose Bradford, the President, was in the chair.

Fellowship.

The following Members of the College were elected to the Fellowship:

Ralph Henry Crowley, M.D.Lond., Charles Hunter, M.D.Aberd., Leonard George Joseph Mackey, M.D.Birm., Edward Burton Gunson, M.D.Ed., William Wilson Jameson, M.D.Aberd., Arthur John Scott Pinchin, M.D.Lond., Adolphe Abrahams, O.B.E., M.D.Camb., Alan Worsley Holmes à Court, M.D.Sydney, Thomas Archibald Malloch, M.D.McGill, Arthur Peregrine Thomson, *M.C.*, M.D.Birm., Graham Selby Wilson, M.D.Lond., Henry Wallace Jones, M.D.Liverp., James Calvert Spence, *M.C.*, M.D.Durh., William Brown, M.D.Oxf., Archibald Edmund Clark-Kennedy, M.D.Camb., Hugh Reginald Dutton, I.M.S., James Purdon Martin, M.D.Pe.T., Macdonald Critchley, M.D.Bristol, Arthur Salusbury MacNalty, M.D.Oxf.

The following were nominated Fellows by the Council under By-law xxxviii (*b*):

Walter Ernest Dixon, M.D.Lond., F.R.S.; John James Rickard Macleod, M.B.Aberd., F.R.S.

Membership.

The following candidates were admitted Members of the College:

Anthony Dominic Abdullah, M.B.Sydney, Edward William Anderson, M.D.Ed., Leonox Gordon Bell, M.D.Manitoba, Charles Allan Birch, M.D.Liverp., Edward John Cronin, M.B.New Zeal., John Nathaniel Cumings, M.B.Lond., Amar Nath Dugga, M.B.Punjab, John Lawrence Howland Easton, M.B.Camb., Phyllis Victoria Lillia Epps, M.D.Lond., Florence Margaret Gamble, M.D.Lond., Stanley Jack Hartfall, M.B.Leeds, Albert Joseph Hawe, M.B.Liverp., Catherine Mary Hext, M.B.Lond., Thomas Alexander Alfred Hunter, M.B.Camb., Simon Kin, M.B.Lond., Isabella Louise Hamilton Livingstone, M.D.Lond., Murdo Mackenzie, M.B.Lond., Lucy Margaret Theodora Masterman, M.D.Lond., Swithin Pinder Meadows, M.B.Lond., Thomas Morton, M.B.Lond., George White Pickering, M.B.Camb., Max Michael Posel, M.B.Lond., Charles Frank Shelton, M.D.Lond., William Arklay Steel, M.D.St. And., Arthur Goronwy Watkins, M.D.Lond., Henry Yellowlees, O.B.E., M.D.Glasg.

Appointment of Representatives.

Sir John Rose Bradford was appointed to represent the College at the jubilee celebrations at the University of Manchester on May 23rd, 1930.

Dr. R. A. Young was appointed representative of the College at the sixteenth annual congress of the National Association for the Prevention of Tuberculosis to be held July 3rd–5th, 1930.

Dr William Hunter was appointed to represent the College on a committee of the People's League of Health to consider the cause and eradication of bovine tuberculosis.

The late Poet Laureate.

By a resolution of the College the President was asked to convey a vote of condolence to the family of the late Poet Laureate, Dr. Robert Bridges, O.M., who was a Fellow of the College.

Licences.

Licences to practise were conferred upon the following 142 candidates who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board and have complied with the by-laws of the College:

M. Ata Ullah, H. B. Bagshaw, G. N. Bailey, *A. H. Baker, J. E. G. Baker, A. N. Barker, F. Bartholomew, G. R. Bashford, D. A. Beattie, D. H. Bolton, A. E. Bowling, Mabel Brewster, R. O. Brooks, *C. C. Bryson, A. Burkhardt, C. E. Burridge, G. G. Cameron, S. N. Chopra, D. S. Chowdhary, J. F. Contes, A. F. H. Cole, Charlotte A. G. Conway, J. H. Conyers, Margaret E. Cook, H. Coorland, H. D. Crousn, H. Curtis, A. L. d'Abreu, C. M. Dell, W. J. D'Rosario, P. G. Dowdell, J. C. E. Dusseau, J. J. Eapen, R. E. M. Fawcett, Sheila J. Ferguson, F. H. H. Finlaison, R. H. Fish,

E. D. Forster, E. V. Frederick, J. D. J. Freeman, †W. W. Gerrard, P. R. Graves, S. R. Gunewardene, H. C. Halge, C. J. K. Hamilton, D. Hay, Geraldine J. G. Hayes, Columba M. D. Heathcote, J. Henry, J. R. Hindmarsh, Cicely L. Hingston, S. W. Holmes, Ethel D. Hopper, L. H. Howells, K. N. Irvine, O. Ive, L. A. Jacob, M. M. St. G. Johnstone, E. G. M. Jones, C. Jotikasthira, *C. C. Kapila, N. F. Kendall, J. D. Kersbaw, S. Lal, F. P. L. Lander, *Grace Law, R. H. Leaver, L. Z. Levy, G. S. R. Little, J. B. Lloyd, H. Lwow, H. G. McComas, S. McDonald, W. McKissock, R. W. Malim, [illegible] P. Markby, J [illegible] F. Murray, F [illegible] C. L. Oakley, G. L. Ormerod, M. Owen, P. M. Oxley, C. H. Pauli, D. D. Payne, M. Phillips, F. E. Pilkington, J. R. F. Popplewell, J. O. Poynton, [illegible]

[illegible]

K. M. Seeda†, M. H Shah, Ursula Shelley, Edna F. Sheridan, L. Silman, S Silman, Phyllis F. L Simon, J. G. Sleigh, Edith M. P. Smith, P. Somasunder, B. Southwell, G. H. G. Southwell-Sander, T. M. Spilhaus, J. K. Stanger, R. W. Stenhenson, B. P. Sur, F. H. Taylor, G. Taylor, J. N. Vasudeva, L. H. Wharton, J. C. G. Whitelaw, D. A. Williams, Rose E. Williams, F. S. Winton, Joyce B. Woods, G. R. H. Wrangham, W. Young.

* M.R.C.S. previously granted.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—R. P. Davies, M. Halperine, J. E. R. Heppolette, C. G. Muller, E. G. Nair, L. J. Pearson.

MEDICINE.—J. Britanischski.

FORENSIC MEDICINE.—J. S. Bury, H. Glynn, J. M. L. Love, A. W. B. Wiggins.

MIDWIFERY.—E. C. Dymond, G. R. Germany, E. G. Nair, C. Seeley, G. Wilsker.

The diploma of the Society has been granted to Messrs. J. S. Bury, E. G. Nair, and L. J. Pearson.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

PARLIAMENT reassembled on April 29th. On that day the Royal Assent was signified to the Army and Air Force Annual Act, and the House of Lords commenced a second reading debate on the Coal Mining Bill. The same day the House of Commons went into committee on the Estimates for the Ministry of Health. The debate, which was chiefly on medical topics, was eventually adjourned. On the following days the Commons debated the changes of taxation which are proposed in the Budget.

The Parliamentary Medical Committee will meet again on May 13th. The British Medical Association scheme for a national medical service is likely to be examined at an early meeting of the Labour Party Committee on Health Policy.

Ministry of Health Estimates.

In committee of the House of Commons, on April 29th, the vote for the salaries and expenses of the Ministry of Health was considered. Mr. GREENWOOD made a statement with regard to the increase in claims for sickness benefit. He said that the report of the Government actuary had made it quite clear that further examination had to take place into this problem. On receipt of the report the National Health Insurance Joint Committee decided to extend the scope of the investigation, and the whole problem was now under the close attention of the officers, administrative and medical, of the insurance departments in all parts of the United Kingdom. When the investigation had proceeded sufficiently far the Approved Societies' Consultative Council would be brought into consultation, as would be the Insurance Acts Committee of the British Medical Association. Out of their investigations and deliberations he hoped that they might get some clearer notion of what lay behind this very large increase in the claims for benefit. He was convinced that there was no simple explanation of the increase. Precisely the same problem had arisen in other countries which had a fairly well-developed scheme of sickness insurance. In those countries the claims had, in recent years, shown a most extraordinary increase. In Germany, for example, the increase in 1929 over 1924 was as large as 70 per cent. He did not wish to be too definite as to the cause of the increase, but in this country the prolonged trade depression had been one important contributory factor. Another factor, the value of which it was difficult to assess, was that people to-day were undoubtedly seeking medical advice earlier than they used to; in fact, the public had been urged repeatedly not to delay treatment, but to obtain it at the earliest possible moment. In so far as the increase of sickness was due to this reason, it was an increase which was to be welcomed, for it meant, in the long run, an economy in the funds of the insurance societies. There were and would be cases where, owing to laxity, either of certification or of administration, persons were in receipt of benefit who were not properly entitled to it. A new regulation was to be issued very shortly which would enable effective disciplinary action to be taken where it was proved beyond doubt that a medical practitioner had failed to exercise reasonable care in the use of certification. With a view to getting more precise knowledge of this situation two separate tests were being conducted. In the first place, an analysis was being made of about 80,000 cases referred to the regional medical officers by a large number of societies all over the country during 1929. It was hoped that when this analysis was complete they would obtain from it a good deal of information not at present available. Secondly, with the object of obtaining more precise knowledge as to the standard which was applied by different medical practitioners in interpreting who was "incapable of work," an investigation would be made very shortly covering a large number of persons in receipt of benefit at a particular date. By those means it was hoped that information would be forthcoming which would enable the Government to bring about a more uniform standard of certification throughout the country. He had decided to make permanent provision for the collection of statistics of the kind to be found in the report of the Government actuary.

Dealing with the health services, he said that maternal mortality was still with them. Out of the detailed investigations of the special committee which Mr. Chamberlain had appointed to consider this complex problem new light, he believed, would come. He hoped the committee would issue an interim report in a month or two. The recommendations of the other committee were under consideration by the Government with a view to devising a scheme of maternal service which would have due regard, on the one hand, to maternity benefit under the National Health Insurance Acts, and, on the other, to the service provided by the local authorities under the Maternity and Child Welfare Acts. With regard to tuberculosis, the experience of village settlements and the principles on which their successful working depended had been brought to the notice of certain local authorities where the conditions seemed favourable to the establishment and maintenance of similar settlements. Even if settlements were provided for all tuberculosis patients for whom they would be appropriate, there would still be a number of people for whom after-care would be required. He hoped that local authorities, as the next move in the campaign against tuberculosis, would consider and experiment in methods of after-care. Less than three weeks ago he announced that the Government had agreed to make a contribution up to £250,000 for the building of a medical school in connexion with the proposed post-graduate hospital and school. The Government contribution was for the buildings, but increased grants would in future be given when the school became a recognized school of the University of London. The scheme had received unanimous approval in both the lay and medical press. He had since communicated with the London County Council and the University of London to get their co-operation, and he hoped in a very short time to have completed the next step by the appointment of a committee representing all the interests concerned to consider the complex problems of planning, finance, and administration. This was perhaps the most important single step which had been taken in the interests of public health since the passage of the original Health Insurance Act, because not only would it be a centre for post-graduate teaching for other parts of the Empire, but it would enable the general practitioners of this country, including 16,000 panel doctors, to have a chance, which they did not enjoy to-day, of keeping in touch with the rapid developments and changes taking place day by day in the art and science of medicine.

Dr. VERNON DAVIES asked if the total expense of the post-graduate courses would be borne by medical men themselves.

Mr. GREENWOOD said he hoped that a certain amount of provision would be made to assist them. Turning to the outbreak of psittacosis, he said that up to the present there had been 112 cases, of which 22 had been fatal. Most, although not all, of the cases had been attributable to parrots from South America. Apparently all birds of the parrot type were liable to the disease. A comprehensive report was in preparation, but meanwhile events had made it imperative that action should be taken under the Public Health Acts to prohibit the importation of parrots for the time being. The new Order would come into operation on May 20th, which gave sufficient time to warn people who might be on the point of importing parrots. He hoped that the public would realize that the course taken was a reasonable one. When circumstances permitted the order would be withdrawn.

Sir KINGSLEY WOOD said that Mr. Greenwood had not shown a sufficient grip of the situation as a result of the information supplied by the Government actuary with regard to the national health insurance scheme. During the seventeen years in which the scheme had been in operation £100,000,000 had been spent on medical treatment and attendances, nearly £500,000 had been disbursed each week in cash benefits, nearly £2,250,000 was being spent on drugs, and some 15,000 members of the medical profession gave 60,000,000 attendances each year to insured persons. The report of the Government actuary was surprising when one recalled the great improvement in national health generally. Yet the Insurance Controller stated that the record in relation to sickness and disablement claims constituted a challenge to all responsible for the welfare of the scheme. One was driven to the conclusion, by reading the reports of the approved societies and the statement

of the Government actuary, that there was a good deal of lax certification. He did not disguise the difficulty of the panel doctor, but it was very remarkable that directly cases were referred from the panel doctor to the regional medical officer, some 55 to 65 per cent. declared off the funds. That called for further explanation from the medical men concerned. This laxity of certification was undoubtedly due, in a considerable degree, to the fact that under the altered conditions only a few days' notice was necessary for a panel patient to change his doctor. The medical men themselves had admitted that there was considerable danger in that direction.

Mr. RHYS DAVIES said that charges had been made against the doctors of excessive certification. If an insured person went to a doctor and said he was not well, no medical man could challenge his statement. It was not that sort of thing of which the societies complained. The allegation was that a young man, wishing to build up a practice successfully and quickly, condescended to the issuing of certificates in competition with other doctors. Whether that allegation could be proved or not he could not say. The Minister of Health was right in making further investigation by way of medical examination. He understood that it was proposed to take a group of societies and conduct a medical examination very shortly.

Mr. MELLER said that if the debate brought home to the doctors a realization of their duties it would have performed a useful purpose. Whatever else might emerge from the proposed inquiry it would be found necessary to go back to the old system under which patients changed their doctors. After subsequent debate, which will be reported next week, the debate on the vote was adjourned.

Medical News.

THE biennial dinner of the Royal Society of Tropical Medicine and Hygiene will be held at the May Fair Hotel, Berkeley Street, Piccadilly, on Thursday, May 22nd. The Marquess of Reading has consented to be present.

DR. J. MURDOCH, Chief of the Department of Radium and Radiotherapy, Brugmann Hospital, Brussels, and Director of the Cancer Centre of the University of Brussels, will give an address entitled "What can we expect from radium in the treatment of cancer?" at the Medical School, Leeds, on Wednesday, May 7th. The chair will be taken at 3.30 p.m. by Mr. J. F. Dobson, professor of surgery in the University of Leeds, and tea will be served after the meeting. Medical practitioners are cordially invited, and those who are able to attend are asked to inform the British Empire Cancer Campaign (Yorkshire Council), 47, Park Square, Leeds, before May 6th.

A SPECIAL meeting of the British Institute of Radiology will be held in the Reid-Knox Memorial Hall, 32, Welbeck Street, on May 8th, at 6 p.m., when Dr. J. Murdoch of the Brugmann Hospital, Brussels, will speak on the problem of dosage in radium therapy. The annual meeting of the Institute will be held on May 15th, at 8.30 p.m., and, after completion of the general business, Dr. Peter J. Kerley will read a paper on the pathology of early pulmonary tuberculosis as revealed by *x* rays. On the following morning a visit will be paid to the Westminster Hospital Radium Annexe in Fitzjohn's Avenue, Hampstead, and in the afternoon, at 5 o'clock, there will be a meeting for medical members, when reports will be received and cases discussed. Further information may be obtained from Dr. Stanley Melville, British Institute of Radiology, 32, Welbeck Street, W.1. The eighth general meeting of the Society of Radiographers will be held in the Reid-Knox Memorial Hall on May 14th, at 7 p.m., when Mr. C. H. Holbeach will read a paper on the planning of an *x*-ray department.

THE annual meeting of the Invalid Children's Aid Association will be held at 18, Carlton House Terrace, on Tuesday, May 6th, at 5 p.m., with Viscount Goschen in the chair. The speakers will include Viscount Burnham, Dr. F. E. Fremantle, M.P., the Rev. Pat McCormick, and Mr. R. C. Sherriff.

THE annual provincial meeting of the Society of Medical Officers of Health will be held at Harrogate on Friday, May 16th, at 4 p.m., when there will be a discussion on rheumatism in its public health aspects. In the evening the members will be entertained at dinner by the mayor and corporation. Those who intend to be present are asked to notify the executive secretary, 1, Upper Montague Street, W.C.1, at once, when they will receive official invitations from the town clerk of Harrogate.

AT a meeting of the Zoological Society of London on May 6th, at 5.30 p.m., Colonel A. E. Hamerton will read a paper on trypanosomiasis in relation to man and beast in Africa. A paper by Dr. S. Zuckerman has been received by the society; it deals with the general nature and homology of the menstrual cycle in the primates.

THE Fellowship of Medicine announces that a four weeks course in dermatology will begin at the St. John's Hospital, Leicester Square, on May 5th, comprising clinical instruction every afternoon and evening, and four special lectures a week, with special work in practical pathology if required. A course in preparation for the M.R.C.P. examination will continue from May 13th until July 4th, consisting of lectures on Tuesday and Friday evenings at 8.30 o'clock in the lecture room of the Medical Society of London, Chandos Street, Cavendish Square, with a lecture-demonstration in general medical ophthalmology on one afternoon, and two special ophthalmic demonstrations. The subjects of other special courses during May are as follows: diseases of the chest at the Victoria Park Hospital, May 12th to 24th, the whole of each day being occupied by demonstrations, lectures, and operations; ophthalmology at the Central London Ophthalmic Hospital, each afternoon from May 19th to June 7th; diseases of children at the Hospital for Sick Children, every morning from May 26th to June 7th; and medicine, surgery, and the specialties at the Queen Mary's Hospital, Stratford (with special reference to tuberculosis), from May 26th to June 7th. Copies of all syllabuses and information on post-graduate work are obtainable from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A SERIES of six lecture-discussions on the difficult child as a medical, social, and psychological problem, will be delivered by the officers of the Child Guidance Clinic of the Jewish Health Organization at Toynbee Hall, Commercial Street, E.1, on Mondays and Thursdays at 5.15 p.m., starting on May 19th. Dr. Emanuel Miller will open the course with a lecture on the general nature and scope of the problem and its treatment, and at the following sessions Dr. Noel H. M. Burke will lecture on the management of a clinic, Miss Beatrice H. Robinson on the functions of the social worker, Mr. M. Fortes on the endowment and education of the difficult child, Dr. Burke on physical factors, and Dr. Miller on the role of the psychiatrist. Tickets (price 1s. 6d. each for the course) may be obtained from the secretary, Jewish Health Organization of Great Britain, 19, Dorset Square, N.W.1.

A POST-GRADUATE course will be held at the Royal Chest Hospital, City Road, on Wednesday afternoons during May, at 3.15 o'clock. On May 7th, Dr. James Maxwell will speak on bronchial carcinoma, and on the following Wednesday there will be a demonstration of cases in the wards by Dr. Barty King. Dr. Saxby Willis will lecture on bronchiectasis on May 21st, and Dr. Ernest Fletcher will deal on May 28th with the electro-cardiographic diagnosis of heart disease.

THE French Orthopaedic Society will hold its twelfth annual meeting at the Faculty of Medicine in Paris on October 10th, 1930, under the presidency of Dr. Albert Monchet of Paris. The subjects chosen for discussion are coxa vara of adolescents, to be opened by Dr. Huc of Paris; and obstetric palsies of the upper extremity, to be opened by Dr. André Rendu of Lyons.

NATIONAL Baby Week will be held this year from July 1st to 7th, attention being concentrated particularly on the need for a National Maternity Service scheme, the better provision of nursery schools, and the promotion of the study of parentcraft. A conference will be held in London on the first three days to discuss the relation between housing and child welfare; infant mortality during the last twenty-five years; the variations in young child mortality in different areas; the relation between the orthopaedic and child welfare centres; and the care of the pre-school child in industrial and rural areas. Further information may be obtained from the secretary, National Baby Week Council, 117, Piccadilly, W.1.

THE first International Congress for Experimental Phonetics will be held at Bern from June 10th to 15th.

THE fourth Congress of the French Societies of Oto-neuro-ophthalmology will be held at Brussels from June 6th to 8th, under the presidency of Professor H. Coppez of Brussels, when the following subjects will be discussed: (1) disturbances of associated movements of the eyes, introduced by Professors Di Marzio and Fumarola of Rome; (2) laryngeal paralysis, introduced by Professors Terracol, Euzière, and Pagès of Montpellier. Further information can be obtained from the general secretary, Dr. Velter, 38, Avenue du Président Wilson, Paris XVIe.

THE forty-fifth German balneological congress was held at Bad Elster under the presidency of Geheimrat Strauss from April 8th to 13th, when the three principal subjects for discussion were the action of iron in mineral springs, the effect of mud baths, and the diet of patients in spas. Next year's congress will be held at Bad Ems at the beginning of April.

THE fourth Congress of the World League for Sexual Reform will be held in Vienna from September 14th to 21st. Further information can be obtained from the Institut für Sexualwissenschaft, In den Zelten 10, Berlin, N.W.40.

AN extensive field of research in vocational guidance is outlined in the report for 1929 of the National Institute of Industrial Psychology. Most of this research has developed since 1924, when the institute started to give vocational guidance in London elementary schools. The statistical results of this experiment, in which twelve hundred children took part, are now being completed. Additional grants have enabled the institute to make experiments of this nature in Fife and in Birmingham. From these and related investigations reports have been prepared for publication on a variety of mechanical and intelligence tests. A special inquiry into vocational tests for motor drivers promises to be of much value in view of the wide adoption of such tests by other countries. Attention has been paid to the organization of blind workers, and means have been devised to assist them in overcoming their feeling of isolation. Progress is also reported in the branch of vocational selection which is engaged in studying the problems involved in choosing candidates for higher administrative positions. In 1929 the membership of the institute increased from 1,318 to 1,430. Fees for factory investigations rose from £15,200 to £16,400; there was a deficit, however, of £558 for the year. Contributions amounting to £13,933 were received for the appeal fund. The report records that the executive committee has approved the constitution of the Scottish Division of the institute at Glasgow.

A NEW *ophthalmoscope will be demonstrated* by Mr. E. F. Fincham at a meeting of the Optical Society to be held at the Imperial College of Science and Technology, South Kensington, on Thursday, May 8th, at 7.30 p.m.

THE issue of *La Medicina Ibera* for April 19th contains an illustrated description of the fourth international Congress of Urology recently held at Madrid, with portraits of the principal speakers, including Sir John Thomson-Walker, president-elect of the next congress, which will be held in London in 1932.

Drs. Levaditi and Sazerac of the Institut Pasteur, Paris, have been awarded the John Scott prize for their introduction of bismuth into the treatment of syphilis.

BY transferring its business establishment from No. 50a to No. 50, Albemarle Street, the publishing house of John Murray has returned to its original business premises which were acquired in 1812, forty-four years after the foundation of the firm. "No. 50" is associated with the first meeting of Scott and Byron, and has been a centre of literary social life for generations. It is now given over entirely to business purposes, but the staircase and drawing room will remain unaltered.

THERE has recently been an increase in the incidence of diphtheria in Geneva as compared with the rest of Switzerland. From 1912 to 1921 the average number of cases notified was 150 to 250 cases annually, the two highest figures being reached in 1914 (244) and 1921 (238). After 1921 there was a progressive and very marked fall, the minimum being reached with 50 cases in 1926. In 1927, however, a rise in the numbers occurred, and became more pronounced in 1928 and 1929.

THE parchment of the Royal Humane Society has been awarded to Dr. Arthur D. Symons, medical officer of health for Shrewsbury, for diving into the Severn and saving a four-year-old boy.

AT an inquest recently the coroner, Dr. F. J. Waldo, stated that in fifteen verdicts of death accelerated by anaesthesia, ether had been given in twelve instances, chloroform in two, and ethyl chloride in one. He had been informed that his suggestion that all ether used should be examined by an analytical chemist, certified as pure, and kept in amber-coloured bottles away from the light, had now been adopted. He added that for several years past he had urged that all anaesthetic cases coming before a coroner should be utilized in connexion with research work, and that coroners should co-operate with experts with a view to the prevention of such accidents.

THE Board of Education has published in pamphlet form a revised list of certified special schools for blind, deaf, defective, and epileptic children in England and Wales, and also institutions recognized by the Board as providing higher education for such children, together with a list of nursery schools. The various institutions are grouped according to type and arranged in counties, details being given of the available accommodation in each. Copies of the list may be obtained from H.M. Stationery Office, price 9d.

THE late Sir William Milligan, consulting surgeon to the Manchester Ear Hospital, who died in December last, has left estate of the gross value of £293,470, with net personalty of £273,056. He bequeathed his medical library to the University of Aberdeen. Dr. George White Drabble of Walton-on-Thames, who died in January, has left unsettled property of the gross value of £475,005, with net personalty of £466,923.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9961, 9962, 9963,* and *9964* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocre Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TREATMENT OF TACHYCARDIA.

"W. D." asks for suggestions for treating a medical practitioner, aged 50, who is suffering from very frequent tachycardia; he describes it as a flutter, the heart tumbling over itself. He feels faint at times. The condition is made worse by smoking and heavy meals. All ordinary remedies have been tried except digitalis. If this is advised, what doses should be given? He now smokes only one pipe a day, and is certainly better.

ALASSIO.

DR. E. E. MAPLES (St. Saviours, Jersey) asks if any reader can give him information regarding the sanitation, water supplies, and general health—especially as regards contagious diseases—of Alassio (Italy).

*** In a letter on sanitation on the Riviera (*British Medical Journal*, January 11th, p. 91) Colonel C. R. Kilkelly wrote very favourably about Alassio.

BUCCAL ULCER.

DR. VAL MACDONALD (Melbourne) writes: In reply to the inquiry of "R. D." (February 8th, p. 267), as the result of much experience I can confidently recommend the following treatment: soak a pledget of wool in pure hydrogen peroxide (10 volumes solution) and place it in contact with the ulcer for two or three minutes; repeat twice or thrice daily. This takes all the burning pain away rapidly, and is more effective in cleaning and promoting healing than any of the usually prescribed caustics, etc., which damage healthy tissue. Then, as a regular mouth wash, prescribe collosol argentum 5j to 3xx water; I use either Crooke's or the Anglo-French preparation. In many of these mouth conditions I am inclined to believe there is a vitamin B deficiency; to supply it I usually prescribe bemax, and it has helped me to obtain some very good results.

INCOME TAX.

Motor Car Transaction: Accommodation.

"G. H. S." raises two points: (1) In January, 1929, he bought a second-hand car for £65 cash; in January, 1930, he bought a new car for £162 10s., receiving an allowance of £65 for the old car—cash value, say, £45. What can he claim? (2) He pays £300 a year for bedroom, sitting room, and consulting room, with all board and attendance. How much is allowable as professional expenses?

*** (1) "G. H. S." has altogether invested £162 10s. in his motor car equipment. The renewal cost claim is of doubtful validity, and would be small (£10, but debars him from the depreciation claim for 1930–31. That claim is, say, 15 per cent. on £162 10s., and, in our opinion, he should claim that allowance only. (2) We can only say that the amount is what represents a reasonable allocation of the £300 between personal and professional use; at a guess, perhaps, £100 would be a reasonable sum for the latter.

Sale of Practice.

"QUEX" sold his practice for a definite sum, two-thirds of which was to be paid at the date of transfer and the remaining one-third in half-yearly instalments. Does this affect his income-tax liability?

*** No. The sums in question are payments of capital; they cannot be deducted by the payer from his gross receipts and are not assessable in the hands of the recipient.

Account for Less than a Year.

"A. C." explains that A and B were in partnership, and made up their accounts to April 30th in each year. B died in December, 1928, and C joined as a new partner with A as from January 1st, 1929. The new partnership is to be treated as a "continuing" practice. If no change in proprietorship had taken place the liability for 1929-30 would have been determined by the profits of the year to April 30th, 1928. In fact, two accounts were made up in 1928—the first for the year to April 30th and the second for the eight months to December 31st, 1928. The assessment for 1929-30 is being fixed on the amount of the profit for the eight months to December 31st, 1928, plus one-third of the profit for the twelve months to April 30th, 1928. The bulk of the firm's accounts are rendered in May and November, and the amounts received in June and December. Consequently, the last eight months of the calendar year contains the great bulk of the year's receipts, and the proposed basis is unfair to the individuals concerned. What can be done?

*** The Finance Act, 1926, Section 34 (1) (*b*) provides that if more accounts than one have been made up to dates within the year preceding the year of assessment, the Commissioners of Inland Revenue shall decide what period of twelve months shall be deemed to be the year for which profits are to be computed. The meaning is clear, and no right of appeal is given. Consequently, the decision to adopt the year to December 31st as the basis of computation must hold good—it is, in any case, the nearest approach possible to the year to April 5th, 1929—that is, the financial year preceding the year of assessment, and prima facie the year to December 31st will be adopted in future. It remains, however, to ascertain the true profit of that year, and the root difficulty—and the point at which the unfairness enters into "A. C.'s" case—is the application of the cash basis. If each of the two periods in question were computed on the basis of the bookings, less an allowance for probable bad debts, the trouble would be avoided. Unless C has bought a share in the former firm's debts, it seems probable that it will be necessary to discard the cash basis for the 1929 and future accounts; if so, and provided that the present hardship is a substantial one, perhaps the best way out of the difficulty is for the accounts to April 30th, 1928, and December 31st, 1928, to be restated on the "bookings" basis. Of course, neither B's executors nor A will be liable in addition to account for tax on cash collected for bookings prior to May 1st, 1927.

Car Transactions.

"E. G. S." bought a 10.9 h.p. car in 1926 for £215, and sold it in 1929 for £50, buying a 7.8 h.p. car for £154. He has not claimed depreciation.

*** The only claim he can make is to treat the actual out-of-pocket expense of replacement as a professional charge against the gross income of the year in which the exchange was effected—that is, to deduct £154–£50=£104, as an expense incurred in March, 1929. As the car is used 75 per cent. for professional and 25 per cent. for private purposes, the net deduction to be made will be £78. It would have been better for "E. G. S." if he had claimed depreciation.

"J. G. C." bought a car in February, 1925, for £180 and sold it in 1928 for £33, buying another car for £260. He was allowed a deduction for income tax purposes of £180–£35=£145. He has now bought a car for £293, receiving £125 for the older one. What is he entitled to deduct? No claim for "depreciation" has been made.

*** The amount of the renewal cost is £260–£125=£135, and only that sum can be deducted as an expense for tax purposes. The excess of the cost of the new car over the original cost of the car displaced (£293–£260=£39) represents improvement of the equipment, and is disallowed as capital expenditure. Depreciation and renewal expenditure cannot be claimed for the same year. If this year no renewal takes place we advise "J. G. C." to claim depreciation then; he will receive a part of the total allowance sooner than by waiting to claim renewals, and an obsolescence claim *can* be made simultaneously with depreciation, provided that the amount of depreciation allowed is deducted in calculating the obsolescence.

"D. A. L." inquires "whether depreciation can be included as a professional expense and at what rate," also "what constitutes professional running expenses."

*** The depreciation allowance is not strictly a professional expense, but is an additional deduction from the gross amount of the assessment to arrive at the amount on which tax is payable. Now that profits are no longer computed on a three years' average basis, however, the distinction is not of great importance. The usual rate of depreciation given appears to be 15 per cent., though 20 per cent. is sometimes allowed, perhaps where the "wear and tear"—which alone is the statutory reason for the allowance—is unusually heavy. Replacement expense cannot be claimed as a deduction in computing liability for a year for which a depreciation allowance is claimed. Seeing that "D. A. L." replaced his car last year, we suggest that he should claim that cost as a professional expense in calculating his profits for 1929, and defer his depreciation claims until 1931-32 and future years.

LETTERS, NOTES, ETC.

TRAUMATIC PROPTOSIS IN A PEKINGESE DOG.

SURGEON REAR-ADMIRAL C. M. BEADNELL, R.N.(ret.), writes: On April 10th my two dogs, a Pekingese and an Airedale, had a difference of opinion, and before we could intervene the smaller dog had managed to get most of his head inside the mouth of the larger one. When we had separated them the Pekingese stood with his head to the ground, clawing frantically at his face and squealing loudly. It was then discovered that the right eye had completely proptosed and lay hanging at the top of the cheek. My wife held the dog's head while I, with a clean handkerchief rinsed out in fresh milk, seized the eyeball and applied a sudden, firm, equable, backward pressure over the socket. I felt the eyeball return into the orbit with a distinct jerk, caused probably by the superadded atmospheric pressure. The little patient protested vociferously, but the moment the eyeball was *in situ* he ceased crying out. For the rest of the afternoon he was somewhat depressed, but he ate a good dinner. For three days there was perceptible exophthalmos, due presumably to post-ocular extravasation, with conjunctival injection and an outward squint. During this period vision was also impaired on the injured side, for the dog cocked his head in looking at objects, so as to bring the sound eye into action. The only treatment was daily syringing with weak argyrol. Six days after the accident the eye was perfectly normal.

THE CERVIX DURING COITUS.

DR. C. P. BLACKER, honorary medical secretary, Birth Control Investigation Committee, writes: The observation by Dr. Jay recorded in the *Journal* of August 10th, 1929 (p. 284), is so important that I would ask the following question: Is it quite certain that the portion of the sheath which had been torn away was fixed in the cervical canal and not in the upper portion of the vagina? The muscles of the pelvic floor form a sphincter round the vagina, and it is the spasmodic contraction of these muscles that is responsible for vaginismus. In the event of the orgasm of the man having preceded that of the woman, and of a spasm of these muscles having followed, the attempt to remove the sheath by the ordinary process of traction would result in the semen being caught up in a tight ball at the distal end of the sheath, which would be effectively locked in the upper portion of the vagina. It is not obvious how the muscular conformation of the uterus would allow of spontaneous cervical dilatation. The forced dilatation of the cervix, in response to the pressure of a foreign body in the cavity of the uterus, falls in a quite different category from the spontaneous dilatation of a sphincter muscle that is devoid of muscular attachments to surrounding bones (such as occurs in relation to the orbicularis oris).

BRITISH-MADE INSTRUMENTS.

SIR JOHN CORCORAN, director of the National Union of Manufacturers, writes: May I ask for the hospitality of your columns to emphasize how desirable it is that our large voluntary hospitals should be equipped with British instruments? Although it may be taken for granted that the members of our hospital committees and the subscribers to hospital funds are patriotic men who appreciate the dire need of our home industries in the present conditions of unemployment, it is a lamentable fact that foreign surgical and electro-medical instruments, etc., are still to be found in many of our institutions. It is safe to say that in the majority of these cases the responsible authorities have no knowledge of the facts, as in too many instances in which foreign appliances are factored by British firms some pains are needed to elucidate the position. I trust, however, that once this matter has been ventilated our hospital committees will ask the firms who quote prices for their equipment to give full particulars in their tenders of the factories in which the work will be carried out, so that they can satisfy themselves that the goods they purchase are not only sold by British firms but are indisputably manufactured in this country. The leading British manufacturers can be trusted to produce the very best instruments, so that in the long run this should not involve any extra cost, and even if in some cases additional money has to be provided at the outset, the purchasers will have the satisfaction of knowing that by their patriotic action they are helping the classes on whom they depend for the maintenance of the institutions they administer so faithfully.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 50, 51, 52, 53, 56, 57, and 58 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 207.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

392. Meningococcal Meningitis.

M. P. BOROVSKY (*Amer. Journ. Med. Sci.*, January, 1930, p. 82) records his observations on 190 consecutive cases admitted to the Cook County Hospital, Chicago, from April, 1927, to September, 1928. 132 (69.5 per cent.) occurred in males and 58 in females. The ages ranged from 3 months to 62 years; 94 were under 14 years of age. Headache, vomiting, and fever were found in every case, and nuchal rigidity. Kernig's and Brudzinski's signs were present in all, except infants under 1 year of age, in whom these two signs were inconstant. Convulsions appeared in 12 cases, petechiae in 23, herpes labialis in 19, strabismus in 24, and ptosis in 4. Deafness was the outstanding sequel; although it was recorded in only 10 cases, this number was considerably increased on re-examination some months after discharge from hospital. The type of deafness, which in 8 was bilateral and in 2 unilateral, was complete loss of hearing due to nerve involvement; recovery or even slight improvement never occurred, although none of these patients died. Only 4 had suppurative otitis media, 2 in patients who recovered and 2 in fatal cases. One patient developed iritis, one chorio-retinitis, one parophthalmitis, and one encephalitis in convalescence from the meningitis. The mortality was 48.9 per cent.; it was highest under 1 year (87.5 per cent.) and over 50 years (100 per cent.), and lowest between 10 and 12 years, when no deaths occurred. The average amount of serum given intrathecally was 162 c.cm., the largest amount 495 c.cm. in 18 days with 15 c.cm. intravenously, and the smallest amount 15 c.cm. intrathecally and 15 c.cm. intravenously. Intravenous serum was administered to 68 patients, 39 of whom recovered, a mortality of 57.3 per cent., which is considerably higher than in cases treated intrathecally only. Cistern puncture was performed in 12 patients, 4 of whom recovered after two or three punctures. A serum rash occurred in 26 cases, in 17 of which intravenous treatment had been given. Of 61 patients who were re-examined from 2 to 16 months after discharge, 34 (55.7 per cent.) were entirely free from complaints, while the rest suffered from deafness (16 cases), lumbar pain (8 cases), vertigo, generalized weakness, aching of the legs, or impaired mentality.

393. Agranulocytosis following Antisyphilitic Treatment.

C. AUBERTIN and R. LÉVY (*Ann. de Méd.*, February, 1930, p. 151) state that it is now incontestable that blood disorders, particularly agranulocytosis, follow antisyphilitic medication; 28 cases have been collected from the literature. The sexes were about equally divided, contrasting thus with the predominance of females in Schultz's disease. The ages ranged from 11 to 50; the greater number, however, occurred between 20 and 40, the period in which the most active specific treatment is employed. Most of the patients were robust, and, apart from syphilis, showed no pathological abnormality. The previous duration of the syphilitic infection varied; in some cases it was recent, but in others the haematological symptoms did not appear for many years after the initial chancre. The blood changes rarely occurred during the first series of treatments, but most usually in the second and third; if arsenobenzol was the drug employed the provocative injection seemed to lie between the fourth and eighth, and in doses between 0.3 and 0.9 gram. A few cases showed some previous signs of intolerance, such as vomiting and fever. The interval between the causal injection and the onset of the agranulocytosis varied greatly; usually it ranged between one and eight days, but in some cases it was prolonged to two or three weeks. The apparent onset is frequently abrupt and marked by chills, fever, intense malaise, and dysphagia; it may be preceded by a prodromal phase of one or two weeks, in which there is lassitude with headache. The agranulocytic syndromes may be classified in three groups: uncomplicated, complicated, and abortive. The first group is uncommon and resembles Schultz's disease. It is marked by an infectious condition, sometimes associated with icterus, and accompanied by bucco-pharyngeal lesions of an ulcero-necrotic type. The blood shows a very marked leucopenia with a complete or almost complete disappearance of the granular elements, but no notable anaemia, no signs of a haemorrhagic diathesis, no diminution in the platelets, and no abnormal forms. The second group may be subdivided into cases in which a simple or haemorrhagic purpura is superimposed on the agranulocytosis, and those in which an acute anaemia, thrombopenia, and haemorrhagic signs are present. In the abortive forms the absence of granular elements is not so marked, and a hypo-polynucleosis rather than an agranulocytosis exists. Short notes of cases of each type are given. The prognosis is grave and the disease usually terminates fatally; cure is rare, being more common in the abortive types. The *chief drug* which causes agranulocytosis is arsenobenzol with its derivatives (the benzol group is known to be particularly haemotoxic), but other arsenical salts and the bismuth salts are also causative agents.

394. Influence of other Infections on Whooping-cough.

M. ERLICH (*Arch. de Méd. des Enf.*, November, 1929, p. 656) remarks that in children suffering from whooping-cough who contract another infectious disease, such as influenza or measles, the symptoms of pertussis become modified or even completely disappear. As it has long been known that vaccination can arrest the paroxysms, Erlich has been in the habit for some years of vaccinating children, especially infants, suffering from whooping-cough during the first stage of the disease. While in some instances it had no effect, and in others merely attenuated the disease, in five out of seventeen cases the disturbance produced by vaccination—namely, the fever, oedema, and formation of pustules—cut short the disease when it was fully developed. The results were much less satisfactory in cases of revaccinations—that is to say, in older children; this being probably due to the slighter degree of vaccinal reaction. Erlich also describes the case of a boy, aged 4 years, almost simultaneously attacked by whooping-cough and meningococcal meningitis. He ceased coughing a few days after the onset of meningitis, but had a recurrence of cough, though no longer of a paroxysmal character, when the symptoms of meningitis had disappeared by the eighteenth day; complete recovery followed. The diagnosis of whooping-cough was confirmed by the presence of two other cases in the same ward.

395. Polyneuritis in Mumps.

F. C. A. THIRIET (*Thèses de Nancy*, 1922–29, No. 414) records a personal case in a man aged 27, and has collected ten others from the literature relating to patients aged from 4½ to 55 years in whom an attack of mumps was followed by polyneuritis. The symptoms were principally motor, but were accompanied by some sensory changes. The condition is usually one of moderate severity, and complete recovery ensues in a period ranging from two to six months. The initial lesion appears to be situated at the level of the spinal roots.

Surgery.

396. Traumatic Asphyxia.

W. R. LAIRD and M. C. BORMAN (*Surg., Gynecol. and Obstet.*, March, 1930, p. 572) review the literature of 132 cases of traumatic asphyxia with notes of five additional cases observed by them. The condition follows severe compression of the thorax and abdomen with complete or partial cessation of respiration for varying periods, as in crushing by panic-stricken crowds, compression by elevators or between vehicles, mine accidents, and the use of machinery in industry and transport. Clinically the purple discoloration of the skin of the face, neck, and upper chest due to numerous minute ecchymoses, and the vivid blood-red conjunctivae resulting from subconjunctival haemorrhage, lozenge-shaped in distribution, are characteristic features. Unconsciousness or convulsions may be present, and unsuspected fractures, especially of the vertebrae, may escape detection unless a thorough *x*-ray examination is made. The possibilities of associated abdominal and intrathoracic lesions must be borne in mind. It has been shown that cyanosis may be produced without change in the oxygen content of the blood, and the cyanosis present in this condition is probably due to capillary and venous dilatation and engorgement. In order to avoid confusion the authors suggest that the term "traumatic asphyxia" should be applied to those cases presenting the typical syndrome in which there has been squeezing compression of the chest and upper abdomen with cessation of respiration for an abnormal length of time; "traumatic cyanosis" should be used when local cyanosis in an extremity follows local trauma or pressure; and "epileptic cyanosis" be applied to that rare condition which is sometimes observed in the face, neck, and upper chest during an epileptic attack.

397. Pott's Disease and Intraspinal Tumours.

L. BÉRIEL and J. ROUSSET (*Journ. de Méd. de Lyon*, March 5th, 1930, p. 141) point out that, while the differential diagnosis between Pott's disease and intraspinal tumour is as a rule definite and clear, in certain instances such is not the case, and even with minute and careful clinical and radiological examinations an exact diagnosis is impossible. In practice, variations in the appearance of the lipiodol injected and in the analyses of the cerebro-spinal fluid can only furnish uncertain presumptions, and the whole key of the diagnosis rests on the evidence of spinal lesion, of Pott's osteitis, or its negation. All clinical effort should, therefore, be centred on an examination of the spine at the point where the compression has been localized. These cases, difficult of diagnosis, may be divided into two groups: those in which tumours may be mistaken for Pott's disease, and the converse. Four cases illustrating the first group, and three instances of the second one, are recorded. The authors maintain that in all doubtful cases laminectomy should be performed. Cases in which Pott's disease is mistaken for tumour are only those in which the disease does not occur in its usual form, but as a circumscribed tuberculous osteitis constituting an intraspinal tumour formation in the form of a tuberculoma or an abscess. In such cases the gravity and fatal prognosis arise not from the osteitis but from the medullary compression, and an operation would be indicated even if a correct diagnosis was made. As early an intervention as possible is always indicated in intraspinal tumours; hence, in such cases of tumour as have been mistaken for Pott's disease, operation should be performed at once. To delay would be prejudicial to the patient. The authors believe that it is preferable to err on the side of excessive intervention rather than on that of undue delay.

398. Torsion of the Omentum.

E. DABASY (*Rinascenza Med.*, February 15th, 1930, p. 85), who reports an illustrative case, states that there are about 144 cases on record of this condition, which was first described by Oberst in 1882. It is usually found in connexion with a hernia. There may, however, be free torsion of the omentum within the abdominal cavity in the absence of any visible cause; and, lastly, torsion of the omentum may occur in connexion with other abdominal or pelvic diseases. According to Wolff and Schuhmann, in 90 per cent. of the cases torsion of the omentum is associated with hernia, while in only 8.7 per cent. has free torsion in the abdominal cavity been found. The age at which torsion of the omentum is most likely to occur is between 30 and 35 in subjects in a good state of nutrition. The symptoms may simulate those of cholecystitis or acute appendicitis. The results of the torsion may be peritonitis, intestinal haemorrhage, embolism, and thrombosis. Treatment consists in resection of the necrotic part of the twisted omentum. Dabasy's patient was a lad, aged 19, admitted to hospital with the diagnosis of perforated appendicitis after five or six days' illness. Laparotomy showed diffuse appendicitis, necrosis of the omentum, and chronic appendicitis. Death occurred twenty-four hours after resection of the necrotic portion of the omentum and the appendix.

399. Congenital Obliteration of the Bile Ducts.

L. COLE and C. H. WHITTLE (*Brit. Journ. Child. Dis.*, October–December, 1929, p. 258), who record two illustrative cases in male infants aged 5 months and 8 weeks respectively, state that, though the cause of congenital obliteration of the bile ducts is unknown, two theories have been advanced to explain it. The first view, which was maintained by John Thomson, is that there is a primary lesion of the ducts with secondary involvement of the liver; while the second view, held by H. Rolleston, is that there is a primary cirrhosis of the liver with subsequent changes in the gall-bladder and ducts. Jaundice, which is the most prominent symptom, generally appears a few days after birth, but sometimes the onset is delayed until much later. Usually it deepens steadily until the skin assumes the greenish hue of prolonged obstructive jaundice. Sometimes there is a transient remission in the depth of the jaundice. A tendency to haemorrhage from the skin and mucous membranes is present in a high percentage of cases. Nutrition is unexpectedly good in the early stages as a rule, and there is often a normal gain in weight for several weeks; later, emaciation and dehydration may become extreme. The liver is much enlarged, unusually firm in consistency, and smooth. Palpable enlargement of the spleen is present in some cases. Death often occurs during the first few weeks, but some children may survive for many months. Ladd has recently reported cases in which choledochoduodenostomy and cholecystotomy were performed with success.

Therapeutics.

400. Bone-marrow in Anaemia from Haemorrhage.

W. BORCHARDT (*Deut. med. Woch.*, March 28th, 1930, p. 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood. In the first series some of the animals were fed with rib-marrow, others with marrow from the long bones. Control animals received a corresponding amount either of fat or of liver extract. The basal diet in each case contained a sufficiency of iron (5 mg. per cent.). Only the animals receiving the red rib-marrow showed a definite increase of weight, and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1.4 mg. per cent. The result was similar but more striking, the dogs receiving the rib-marrow regaining their haemoglobin far more quickly than the others. In order to find out if possible the nature of the substance responsible, animals were then fed with (1) dried rib-marrow which had been heated for six hours at 100° C.; (2) residue from dried rib-marrow after extraction by acetone and petroleum ether; (3) the (iron-containing) ash from dried rib-marrow; and (4) the lipoids extracted from the marrow. The heated preparation proved just as active as the original substance, the extracted (lipoid-free) marrow was also active, but the ash and lipoid extract had no influence on haemoglobin formation, as compared with the control animals. The author concludes that the oral administration of red bone-marrow has a favourable influence on the regeneration of blood after haemorrhage, but that further research on patients will have to show what types of human anaemia respond to this treatment.

401. The Diuretic Action of Theobromine.

P. SAVY and P. DELORE (*Journ. de Méd. de Lyon*, March 5th, 1930, p. 155) deprecate the tendency to an indiscriminate use of theobromine as a diuretic, and give a critical analysis of the pharmacodynamic and clinical facts concerning this drug. Theobromine, as well as caffeine, is a xanthine derivative and the therapeutic properties of these bodies are manifested in different degrees according to the number and position of the methyl radicals in the xanthic nucleus: theobromine and its derivatives are dimethylxanthines, caffeine is a trimethylxanthine. The former are principally diuretics and secondarily cardio-tonics, while the converse is the case as regards caffeine. After discussing the various actions attributed to theobromine, the present authors state that its diuretic properties are due to an increase in the renal circulation and in the filterable part of the blood; direct epithelial action is doubtful. The dosage varies with different authorities, but 2 grams is recommended as an average dose; in computing the dosage account must be taken of the patient's weight, which is often considerably increased by the anasarca. The employment of theobromine for different types of nephritis is critically discussed. Widal and Javal, and Bellon have established the elective action of the drug on the elimination of chlorides and the increase of the urinary chlorides following its administration. Savy and Delore consider that it is a dechloridizing agent and that its use should be limited to nephrites with oedema accompanied by chloride retention. The cases should not be too advanced, and the treatment should be combined with a chloride-free diet. In other forms of nephritis its administration is of no benefit and may even be harmful. In cirrhotic anasarca, inflammatory effusions (notably pleurisy), hypertension, obesity, and gout it is also ineffective. In cardiopathies its diuretic action is only apparent when it is combined with digitalis. In acute nephritis and in acute exacerbations of chronic nephritis the drug is absolutely contraindicated. Short notes are given of the following derivatives of theobromine: theocine or theophylline, injectable theobromine or allyltheobromine, and diuretine, the double salicylate of theobromine and sodium.

402. Treatment of Diphtheria Carriers.

M. LISBONNE, P. DEVÉZE, and LABRAQUE-BORDENAVE (*Paris Méd.*, March 8th, 1930, p. 234) record their observations on fourteen diphtheria carriers treated by insufflations of a powder consisting of 1 to 2 grams of the neutral oxyquinoline sulphate in 100 grams of bismuth carbonate, the insufflations being made once or twice daily. The diphtheria bacilli disappeared in four to ten days in all except one case, in which they were still present after sixteen days, but subsequently disappeared spontaneously. Although the number of cases is small, the authors think their results are sufficiently encouraging for the method to be tried on a large scale.

Dermatology.

403. Early Cases of Elephantiasis Nostras.

F. WIRZ (*Derm. Woch.*, March 8th, 1930, p. 336), who records an illustrative case, remarks that most of the extensive literature on elephantiasis nostras deals with the late stages of the disease; early cases, however, are not so rare as this would suggest. During the last three years Wirz has seen eight examples among about 5,500 skin diseases of all kinds in the women's department of the Munich University skin clinic, as well as two cases in consulting practice. The cases of elephantiasis seen in the clinic were more numerous than those of pemphigus, Darier's disease, mycosis fungoides, and other skin conditions regarded as rare. In most of the patients the lesions of elephantiasis were on the face; in three the disease had started round the mouth, in two round the nose, and in another two the external ear was affected. In only two cases, both in women, were the legs affected, in one the right and in the other the left. The most characteristic feature in all the cases was the occurrence of sudden local thickening and redness of the skin, usually accompanied by fever. Treatment consisted in the application of ichthyol ointment and tincture, followed by grey ointment, but most importance was attached to an energetic protein therapy in the form of terpichin, aolan, and the patient's own blood injected every second or third day. Complete recovery followed in each case.

404. Erythema Nodosum.

H. RATTNER (*Arch. Derm. and Syph.*, February, 1930, p. 206), who records an illustrative case, states that "nodal fever," usually known as erythema nodosum, is a mildly infectious disease, commonest in the spring and autumn, and with an incubation period of about fourteen days. Prodromes may be mild or intense, the eruption is definite and uniform, and convalescence, though usually uneventful, may be fraught with danger. The infection is most frequent in young women. Many regard the condition as associated with tuberculosis. Since the experimental evidence for this theory is small, it has been suggested that the condition is an acute infectious disease with the special likelihood of tuberculosis developing in the period of post-febrile debility. In Rattner's patient, a woman aged 26, the lesions were situated on the breasts, chest, and upper part of the arms. Physical and *x*-ray examinations of the chest were negative, and a blood culture was sterile, but no tuberculin test was performed. Recovery was uneventful. V. BOGANOVITCH (*Arch. Dis. Child.*, February, 1930, p. 56) records five cases, in children aged from 3½ to 7½ years, in whom an attack of influenza was followed by erythema nodosum. In view of the fact that several French writers, such as Poncet, Pons, and Landouzy, regard erythema nodosum as tuberculous in nature, it is noteworthy that in each case the Pirquet test was negative. Boganovitch comes to the conclusion that influenza was the predisposing if not the exciting cause of the eruption.

405. Benign Aponeurotic Sclerema.

C. AUDRY and J. GABRAT (*Ann. de Derm. et de Syph.*, February, 1930, p. 161) describe a pseudo-sclerodermic syndrome, first isolated in 1902 by Buschke under the name of "scleroedema of adults"; the designation "benign aponeurotic sclerema" seems to the authors to be more appropriate, since true oedema is absent, the fascia is chiefly involved, and the disease is seen in children as well as adults. It is of marked benignancy, being distinguishable from the sclerodermas by the absence of pigmentary and angioneurotic phenomena, and of trophic disturbances and mutilations, by the fact that the hands and feet escape, and by the marked involvement of the aponeuroses. The case is reported of a man, aged 68, who had for some months presented a pseudo-sclerematous condition of the fascia of both legs and knees, and of the lower external parts of the thighs, extending to the buttocks posteriorly. The epidermis of the legs was red and cracked, but there were no other symptoms, such as pigmentary or atrophic troubles. Latent syphilis was suggested by a weak positive Wassermann reaction of the blood, and the positive reaction of the cerebro-spinal fluid; moreover, rapid cure followed the exhibition of potassium iodide and arsenical treatment. Sellei distinguishes two types of this affection. In one there is progressive induration of the deep subcutaneous tissue, the aponeuroses, and muscles; in the other the aponeuroses and muscles are affected. Most frequently the induration commences on the neck, and extends to the face, back, and arms, the hands always remaining unaffected. Sometimes the lower limbs are first attacked, with extension to the buttocks but with no involvement of the feet. Occasionally the disease is slightly painful, the pain occurring usually at night, and being increased by the warmth of the bed. Occasionally also the movements are rendered stiff and difficult. The etiology of the disease is still unknown; it may be due to pyrexias, infections, or possibly syphilis. The pathogenesis is also uncertain; the histological changes do not show typical degeneration, and the symptoms point to disorders in the functioning of the endocrine glands. The usual tendency to recovery indicates that the glandular lesions are transitory and curable. The authors suggest that this disease may be classed with the different varieties of so-called rheumatic cellulitis.

Obstetrics and Gynaecology.

406. Heart Disease and Pregnancy.

F. S. HONE (*Med. Journ. of Australia*, January 4th, 1930, p. 2) considers that the problem of pregnancy in patients with heart disease is essentially threefold, comprising (1) the advisability of marriage, (2) the advisability of pregnancy, and (3) the question of terminating pregnancy. He refers to the older discussions about the relative dangers of the various valvular lesions, but considers that a decision for or against marriage should be based more upon effort tolerance, the presence or absence of symptoms, evidence of recent progress of the disease, and the economic aspect. The final decision should be made by the patient when the exact position has been explained to her. While heart failure in pregnancy occurs in about one in seven of patients with valvular disease, Gammeltoft has shown that signs of cardiac insufficiency arise in about the same proportion of apparently normal patients. A history of failure, with or without pregnancy, the presence of associated pelvic or renal disease, and a poor response to exercise tests are strong contraindications against pregnancy. With regard to the termination of pregnancy, the author believes that decision is most difficult after the early months and later when the child is viable. This question is dealt with more fully by W. A. VERCO (ibid., p. 6). He insists upon the careful observation of cardiac patients during pregnancy, and believes that much difficulty may be avoided by sufficient rest and suitable dietetic and medicinal treatment. Labour should be induced if orthopnoea supervenes, when pulmonary oedema or a pulse rate of over 100 persists, and when a distinct forcible apex beat is present outside the mid-clavicular line in aortic regurgitation. The use of forceps in parturition saves exertion on the part of the patient, and is to be recommended in most cases. Ether anaesthesia is advisable unless there is pulmonary oedema, in which case chloroform should be employed. The author remarks upon the danger of circulatory failure after delivery, and suggests that adequate digitalization and the application of firm pressure to the upper abdomen are valuable preventive measures.

407. ACCORDING to W. D. REID (*Amer. Journ. Obstet. and Gynecol.*, January, 1930, p. 63) there is a considerable difference in the published statistics of the mortality of cardiac patients who are pregnant. Cardiac disease was alleged as the cause of nearly 20 per cent. of the total maternal mortality during a four-year period at the Boston Lying-in Hospital, and of 28 per cent. of the deaths at the Faulkner Hospital, Boston. Analysis of 830 cardiac patients who were pregnant, reported in the literature, showed a mortality of 5.1 per cent., while the cardiac deaths constituted 8.1 per cent. of the deaths from all causes during pregnancy and parturition. The combined statistics from the Boston Lying-in Hospital, New York Lying-in Hospital, and the Robinson Memorial, Boston, show 45,320 deliveries, 280 deaths from all causes, and 42 deaths from cardiac disease, the cardiac mortality amounting to 10 per cent. of the deaths from all causes. Reid suggests that the difference in various published statistics is due to the majority of recent observers classifying their cardiac patients according to the degree of insufficiency of the heart rather than according to the structural lesions diagnosed. He concludes that pessimism regarding the prognosis of all cardiac patients who are pregnant is not justified by facts.

408. Prevesical Abscess in Pregnancy associated with Asthma.

F. CHATILLON (*La Gynécol.*, November, 1929, p. 651) reports a case of a woman suffering from the asthma of pregnancy who developed a metastatic abscess in the cave of Retzius. The history of her first confinement showed that the patient had an attack of cyanosis, with dyspnœa and expectoration, immediately after delivery. Several hours later her condition became normal. For the four succeeding days similar attacks supervened, with a gradually diminishing dyspnœa. The patient left the hospital on the eighth day and had no further symptoms. The diagnosis made was an acute œdema of the lung superimposed on a previous bronchitis. Eighteen months later the patient became pregnant again, and immediately after conception attacks of asthma began. For five

weeks she was treated in a private clinic and became much better, but immediately she returned home the asthmatic crises started again. During the attacks there was intense dyspnœa without expectoration. The patient was then admitted to hospital. Nothing abnormal was discovered in the heart or nervous system, and *x*-ray examination of the lungs was negative. The Wassermann and Besredka tests were negative. All treatment had but a transitory effect on the asthma. The patient then developed broncho-pneumonia, and as she recovered from this the dyspnœic crises disappeared. Two days after her recovery the patient complained of pain in the lower part of the abdomen anterior to the gravid uterus. After administration of opium she felt better and was allowed to get up; but a week afterwards pain above the symphysis was complained of, and the labia were found to be œdematous. Four days later puncture of a swelling above the symphysis revealed pus, and a transverse incision released 200 c.cm. of pus lodged in the prevesical space of Retzius. The pus was liquid, homogeneous, and odourless; cultures were sterile. For ten days recovery progressed well and the wound almost healed, but on the twelfth day the right labium was swollen and tender; on incision 20 c.cm. of yellowish pus were withdrawn, cultures being sterile. The patient left hospital twelve days later in a good state of health. There were no dyspnœic crises during this period, and the pregnancy had advanced to the eighth month. After her discharge she had an occasional slight asthmatic attack. A month later she returned to hospital and had a normal and rapid confinement. Since that time no attacks of asthma had occurred, and the patient was in good health. Although pneumococci were not found in the pus to confirm the diagnosis, Chatillon considers that the suppuration in the cave of Retzius was due to a metastasis from the broncho-pneumonia. The crises of coughing had, in all probability, caused small lesions of the vessels, with ensuing extravasation and secondary infection.

409. Pregnancy after Malaria Treatment of General Paralysis.

R. GLAS (*Zentralbl. f. Gynäk.*, December 21st, 1929, p. 3458) records the case of a single woman who, at the age of 35, was treated for general paralysis of the insane by artificial malarial infection; seven years later, during an interval between asylum treatments, she became pregnant. Twin children, one of whom survived for twenty-nine hours, were born after a brief labour, which was so far from painless that ethyl chloride inhalation was required during the end of the second stage. The patient died on the ninth day of acute septicæmia, caused probably by self-infection. Several totally painless labours, one with forceps extraction, have been reported in general paralytics. Strassmann has recorded the birth of a healthy child after malaria treatment of a general paretic who had previously had two miscarriages; Weissmann has reported the birth of two healthy children after similar treatment of a patient who had been sterile during sixteen years of married life. Varying opinions are held with regard to the unfavourable influence (seemingly apparent in the present case) of pregnancy on the dementia of paretics, and with regard to the justifiability of artificial termination in them of pregnancy or fecundity.

Pathology.

410. Eosinophilia during Liver Treatment.

E. MEULENGRACHT and S. HOLM (*Ugeskrift for Laeger*, January 2nd, 1930, p. 7) report observations on 54 patients fed on liver, in connexion with 37 of whom differential blood counts were made. The patients were classified according as they were given raw liver, fried liver, liver extract, or intermittent or mixed liver treatment. In the first class, 22 patients were given raw calf's liver, the initial daily dose being usually 200 or 300 grams, and the later dosage being the same or somewhat less. With only a few exceptions eosinophilia set in quite suddenly, after about four weeks, and reached high figures (20 to 40 per cent., and in one case 74 per cent.). This condition persisted as long as the raw liver was eaten, even when this dietary was maintained for over a year and a half. The eosinophilia developed at the expense of the neutrophil cells, which dwindled in numbers both absolutely and in relation to the other cells. Four control patients, not suffering from pernicious anaemia, but given 250 grams of raw calf's liver, developed a high degree of eosinophilia after about four weeks. In the second class, in which fried calf's liver was given, there was one patient with pernicious anaemia with three controls; practically no eosinophilia was observed in any of these four cases. In the third class, among the 12 patients with pernicious anaemia and one control case who received liver extract corresponding to 200 to 600 grams of whole liver, little or no eosinophilia developed. In the fourth class, in which intermittent or mixed liver treatment was given, it was observed that the eosinophilia could be correlated with the periods when raw liver was given; it disappeared when the other forms of liver medication took the place of the raw liver. The authors conclude that eosinophilia is, so to speak, "a casual by-product" of treatment with raw liver, occurring independently of the curative action of raw liver on pernicious anaemia. They think this eosinophilia is a harmless phenomenon.

411. The Identity of Typhus and Mexican Typhus Fever Viruses.

H. MOOSER and C. DUMMER (*Journ. Exper. Med.*, February, 1930, p. 189) record evidence suggesting that the specific organism of Mexican typhus or tabardillo is identical with *Rickettsia prowazeki*, the causative organism of typhus. If the tabardillo virus is injected intraperitoneally into guinea-pigs it gives rise to a scrotal swelling; examination reveals the presence of small [illegible] in the tunica vaginalis. The same microscopical picture is seen in the tunica vaginalis of [illegible] intraperitoneally with an emulsion [illegible] *rickettsia prowazeki*. Careful comparison [illegible] *prowazeki* in the louse's gut and the tabardillo virus in the tunica vaginalis of inoculated guinea-pigs were indistinguishable in form, staining, or mode of intracellular multiplication. Further experiments showed that it was possible to infect lice by feeding them on monkeys inoculated with a strain of tabardillo. Similarly, lice subjected to rectal inoculation with an emulsion of tunica vaginalis from guinea-pigs infected with tabardillo became infected with rickettsiae. It would appear as if the tabardillo virus behaved in the same way as the true typhus fever virus. All attempts to separate the tabardillo virus from *Rickettsia prowazeki* in mammals and in lice have failed, and the authors therefore conclude that the two viruses are identical.

412. Specificity of Soluble Streptococcal Toxins.

G. F. and GLADYS H. DICK (*Journ. Amer. Med. Assoc.*, December 7th, 1929, p. 1784) report an investigation of the specificity of the soluble toxins produced by haemolytic streptococci. Recently confusion has arisen because some workers in applying the neutralization test for identification of streptococcal toxins have found cross-neutralization between scarlet fever toxin and erysipelas antitoxin. It had been assumed that although the soluble toxins produced by various haemolytic streptococci were different, they still had certain common factors which were not specific and which overlapped. The present authors conclude that the soluble toxins produced by scarlet fever and by erysipelas haemolytic streptococci are immunologically specific and distinct. They found that no direct relation was demonstrable between spontaneous immunity to scarlet fever and spontaneous immunity to erysipelas toxin. An attack of scarlet fever does not confer immunity to erysipelas, nor does artificial immunization with scarlet fever toxin produce immunity to erysipelas. Erysipelas streptococci yield considerably weaker toxins than scarlet fever streptococci. Erysipelas antitoxin produced by immunizing against toxin from a single strain of erysipelas streptococci neutralizes the homologous toxin and toxins specifically from other strains of erysipelas. It does not neutralize scarlet fever toxins. Scarlet fever antitoxin obtained by immunizing a horse with toxin from one strain of scarlet fever streptococci neutralizes the homologous and other scarlet fever toxins, but does not show any cross-neutralization with erysipelas toxins.

413. Chemistry of the Lipoids of Tubercle Bacilli.

R. J. ANDERSON and E. G. ROBERTS (*Journ. Biol. Chem.*, January, 1930, p. 529) cultivated a strain of bovine tubercle bacillus on the Long synthetic medium, and after three months conducted a series of extractions to determine the amount of lipoid substance present. The bacilli were first extracted at room temperature for ten weeks with alcohol-ether solution. The extract was treated with acetone, and the bacterial residue was extracted with chloroform. By this means the lipoids, which constituted 13.4 per cent. of the dried bacterial bodies, were separated into three fractions—a phosphatide fraction, an acetone-soluble fat fraction, and a chloroform-soluble wax fraction. The bacterial residue still contained a large amount of fat or wax-like material, which could only be removed after drastic treatment with alkali or acids; the figure of 13.4 per cent. does not therefore represent the total lipoid content of the organisms. Preliminary tests indicated that the phosphatide fraction was antigenic when inoculated into rabbits, and gave a positive precipitin reaction with serum from tuberculous cattle. Besides the lipoid bodies, a polysaccharide was extracted which appeared to consist of both simple and complex sugars; it constituted 1.09 per cent. of the dried bacterial bodies.

RYVITA

CRISPBREAD

RYVITA
1930
TALKS
No. 3

IS RICH IN FLUORINE

"Fluorine, which is indispensable for forming the enamel of the teeth, is found, so far as is known at present, in sufficient quantity probably only in rye, for which reason the peoples who eat rye bread made of the whole grain have the soundest teeth."

Statement by Dr. Bircher-Benner, the famous Dietitian.

Ryvita Crispbread, because of its richness in the natural organic salts of iron, phosphorus and lime, is essentially a bone and tooth-builder. And its dry, crisp form ensures thorough mastication, and so keeps teeth clean. This also ensures a regular massage of the gums during mastication; thus by constant stimulation of their circulation, making and keeping the gums strong, firm and healthy.

We shall be very pleased to send Free Samples and full particulars to any interested Member of the Profession.

No. 5a. BELT (Bailey's Patent) FOR FLOATING KIDNEY.

No. 3. BELT (Bailey's Patent) for PROLAPSUS UTERI.

ELASTIC STOCKINGS FOR VARICOSE VEINS.
Uniform support maintained throughout.
Superior to any bandage; harm often being caused through unequal pressure in winding round the limb.
97 YEARS' REPUTATION FOR BEST QUALITY AND COMFORT.

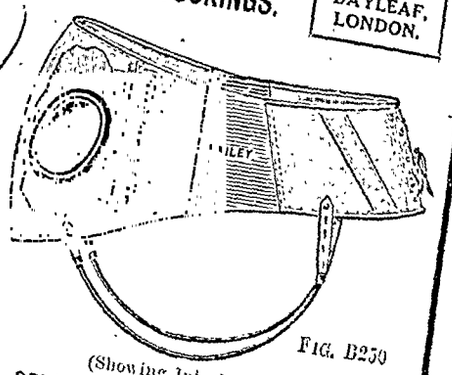

FIG. B250
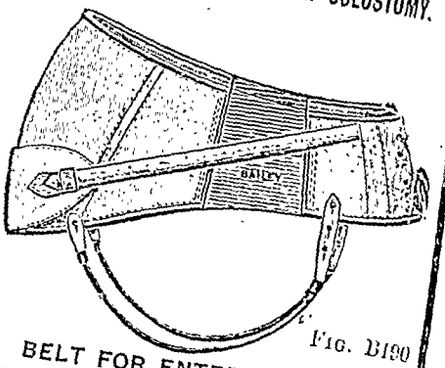
(Showing Interior of Cup.)
SPECIAL BELT FOR AFTER COLOSTOMY.



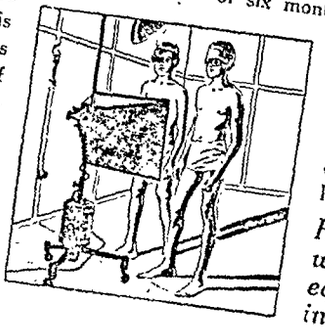


FIG. B190
BELT FOR ENTEROPTOSIS.

"A Valuable addition to our Methods"

A Public Health Authority writes:

"With the exception of 5 cases, all who completed the full course showed considerable improvement. This was particularly noticeable in cases of rickets, which reacted best of all and showed marked improvement in general muscular tone. In cases of children suffering from anæmia and debility, parents almost invariably reported greatly improved appetite and muscular activity, and more refreshing sleep.

Gratifying results were also obtained in cases of corneal ulcers and of rheumatism. The experience of six months' use of the lamps indicates that ultra-violet radiation is a very valuable addition to our methods of treatment. Both types of lamps gave good results, but cases appeared to show signs of improvement more quickly with the mercury vapour lamp than with the carbon arc."

Here again Hanovia Lamps were used. Standard equipment in 163,000 installations.

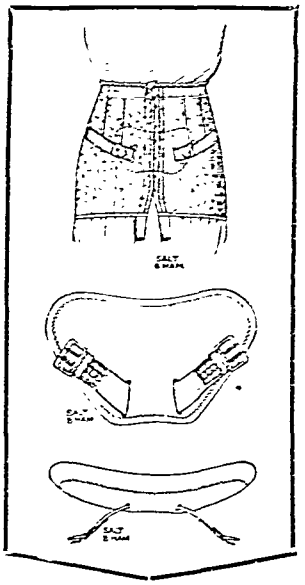
Salt and Son Ltd.



SALT'S PATENT GASTROPTOSIS CORSET

All the well-known features of Salt's Gastroptosis Belt are incorporated in this Corset.

This is an instance where, by supplying a special Corset, the necessity is obviated of the patient wearing a belt in addition to ordinary corsets.

Fig. A shows slightly dilated and much dropped stomach radiographed in the upright position immediately after partaking of a barium (6 oz.) "Umbrose" meal. The greater curvature projects 3½" below a line drawn between the iliac crests.

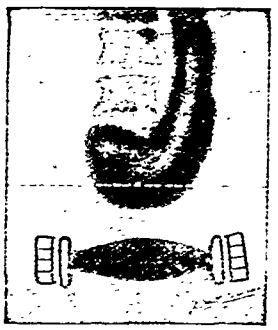


Fig. B shows same stomach radiographed 15 mins. later, the patient having lain upon a couch, the bottom feet of which were raised 9". The Belt was then applied, the patient allowed to walk about 5 or 6 minutes, and the radiograph taken in the upright position.

BRITISH SPAS are best

and membership *of the* British Spas Federation is a guarantee of efficiency.

AT British Spas treatment is only given (except in a few minor cases) upon medical prescription.

At British Spas the Staffs are educated and properly trained, and, in some cases, medically trained and medically certificated.

Equipment and administration are thoroughly up-to-date and scientific. Every new treatment is tested and reported upon before being adopted.

British Spas are also remarkably fortunate as regards situation, scenic beauty, and pure air. These factors, combined with the social amenities of a home town, aid the cure considerably.

A New Medical Handbook is being published, specially prepared for the use of the medical profession. A copy will gladly be sent you if you will write to the Hon. Secretary, Box I. British Spas Federation, Thermal Baths, Buxton, or to the Managers of any of the Spas here mentioned.

BATH Hot Springs (120° F.). Radio-active. Royal Baths extensions now open.

BUXTON Radio-active Mineral Water. New Natural Baths. 3 guineas Course.

CHELTENHAM Five Natural Waters. Modern Baths.

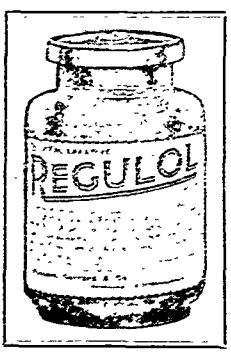
AN ADVANCE IN THE SCIENCE OF DERMATOLOGY

Lessons learnt during the Great War have been having their full effect during the past few years. In no sphere of medical research is this more evident than in Dermatology. For instance, it can now be truthfully said that the peat distillate principle, so intensively tested in the hospitals in war time, has gained the favour of the greater number of medical practitioners in this country.

Having this fact in view, Peat Products Ltd. produced an ointment containing the peat distillate principle, all the therapeutic qualities of Sphagnum moss, in an easily administered form. They call this ointment "Sphagnol," and it can be bought at any chemist's. It is backed by Sphagnol lotion, soaps, and suppositories, which also contain the peat distillate principle.

If you would like to test these products please write for samples to Peat Products (Sphagnol) Ltd (Dept. B24), 21, Bush Lane, London, E.C.4.

The Ideal Laxative



REGULOL REGD.

"REGULOL" IS AVAILABLE IN TWO FORMS: "PLAIN," or "COMPOUND." The latter is a combination with Phenolphthalein 4 grains per oz., and is indicated in more acute forms of Constipation where the simple lubricating effect of Paraffin is insufficient.

CUXSON, GERRARD & Co., Ltd.
Oldbury, *Birmingham.*

IT is a highly palatable Emulsion of Liquid Paraffin with Agar-Agar, possessing all the advantages of the former without its objectionable qualities, and forming probably the best possible remedy for Chronic Constipation in Children and Adults.

SAMPLE ½lb. JAR FREE ON REQUEST.
Please indicate whether Plain or Compound is required.
(This offer is limited to the British Isles.)

The *only* product of its kind

SOLID IODINE

Safe—useful—portable

The manifold uses of H_2O_2 are known to all members of the medical profession. 'Peroxtik' is the only solidified form of Peroxide of Hydrogen in existence. Its utility, portability and safety is obvious, and every tube is guaranteed to maintain its original 10-volume strength for a reasonable period. Medical men interested in H_2O_2, who are desirous of testing 'Peroxtik,' should not fail to write for a free sample tube to ARTHUR H. COX & Co., LTD., 93, Lewes Road, Brighton.

'Peroxtik'
SOLIDIFIED PEROXIDE OF HYDROGEN
in neat, handy glass tubes.

Suppresses putrefaction and bacterial infection of the colon

Lactose and Dextrin owe their value in changing the intestinal flora to the fact that they are more slowly absorbed than other carbohydrates. Because of this slow absorption they are able to reach the colon in sufficient quantity to cause a luxuriant growth of productive flora, thus keeping down putrefactive and poison-forming germs. Lacto-Dextrin effectively disposes of the disadvantages of both Lactose and Dextrin in their crude form. It is a palatable and agreeable combination of the two, and is highly efficient in producing the growth and development of both B. acidophilus and B. bifidus in the colon.

Samples and literature will be sent on request to the Medical Profession on application to Sole Distributing Agents for U.K. and Irish Free State, COATES & COOPER, 41, Great Tower Street, London, E.C.3

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions

The Secretary of the Bank will be pleased to send a copy on application

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for *hydrotherapy* by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week For further particulars apply to—

Dr E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position [illegible] comfortable arrangements affords every facility for the relief and cure of and mentally afflicted. Warwickshire and Coventry JOINT COMMITTEE FOR TUBERCULOSIS.

MEDICAL SUPERINTENDENT OF THE WARWICKSHIRE KING EDWARD VII MEMORIAL SANATORIUM, HERTFORD HILL, near WARWICK. (195 Beds.)

Applications are invited from male qualified and registered Medical Practitioners for the post of Medical Superintendent of the Warwickshire King Edward VII Memorial Sanatorium, Hertford Hill, near Warwick. The person appointed must devote the whole of his time to the duties of the office, and must have had special practical experience in the treatment of tuberculosis in sanatoria, dispensaries, and otherwise, and must be thoroughly acquainted with modern methods of diagnosis and treatment.

In addition applicants must have held the appointment of Tuberculosis Officer or Medical Superintendent with the approval of the Minister of Health, or who, subsequent to qualification:

(1) have had at least three years' experience in the practice of his profession;
(2) have spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical or surgical cases; and
(3) have received special training, for a period of not less than six months, in the diagnosis and treatment of tuberculosis.

The salary is at the rate of £800 per annum, plus unfurnished house, including fuel, light, and laundry, valued at £100 per annum, but not board. The salary will be subject to a deduction of 5 per cent. in respect of contributions under the Local Government and Other Officers Superannuation Act, 1922; in addition, motor car allowances in accordance with the Committee's scale and reasonable travelling expenses are paid.

The appointment is also subject to a satisfactory medical examination by one of the Committee's independent Medical Referees.

Forms of application and statement of the duties and terms of the appointment can be obtained from the undersigned. Applications, marked "Medical Superintendent," with copies of not more than three recent testimonials, must be received by me not later than Monday, May 26th.

Applicants must not be over 40 years of age.

Canvassing, directly or indirectly, will be considered a disqualification.

L. EDGAR STEPHENS, Clerk of the Joint Committee.

42, Warwick Street, Leamington.
April 28th, 1930.

Lancashire County Council.

PUBLIC ASSISTANCE COMMITTEE.

PARK HOSPITAL, DAVYHULME, near MANCHESTER.

APPOINTMENT OF JUNIOR RESIDENT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners (men) for the appointment of a Junior Resident Medical Officer at the above Hospital. Candidates should be unmarried. The appointment will, in the first instance, be for a period of six months, the successful applicant being eligible for re-appointment for a further period of six months at the end of that period. The salary is at the rate of £200 per annum, together with the usual residential allowances.

The Hospital comprises 500 beds.

Applications, accompanied by copies of not more than three testimonials, should be addressed to the County Medical Officer, Public Assistance (Hospital and Medical) Department, County Offices, Preston, not later than May 17th.

County Offices, Preston.
April, 1930.

GEORGE ETHERTON, Clerk of the County Council.

County Council of the West RIDING OF YORKSHIRE.

MIDDLETON-IN-WHARFEDALE SANATORIUM.

The County Council of the West Riding of Yorkshire invite applications for the appointment of RESIDENT ASSISTANT MEDICAL OFFICER (male, unmarried) at the Middleton-in-Wharfedale Sanatorium, near Ilkley (300 beds). Salary £350, with board.

Further particulars and form of application may be had from the undersigned, by whom all applications, together with copies of not more than three recent testimonials, must be received not later than May 12th.

County Hall, Wakefield.
April, 1930.

J. CHARLES McGRATH, Clerk of the County Council.

Metropolitan Borough of HAMMERSMITH.

TUBERCULOSIS OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited for the appointment of Tuberculosis Officer and Assistant Medical Officer of Health for the Borough of Hammersmith.

The salary attaching to the appointment is £750 per annum, rising by annual increments of £50 to a maximum of £1,000, but in fixing the commencing salary regard will be had to the qualifications and experience of the gentleman appointed.

Candidates must be qualified to hold an appointment as Tuberculosis Officer in accordance with the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations, 1930, and must also possess the Diploma of Public Health.

The gentleman appointed will be required to devote his whole time to the duties of the office. The chief duties will be in connection with tuberculosis, but the successful applicant will also be required to assist in the general work of the Public Health Department under the supervision of the Medical Officer of Health.

The appointment will be subject to the provisions of the Council's Superannuation Scheme, and the successful applicant will be required to pass a medical examination.

Applications on forms to be obtained from the undersigned, accompanied by copies of not more than three recent testimonials, must be delivered at the Town Hall, Hammersmith, W.6, in envelopes, endorsed "Tuberculosis Officer," not later than May 12th.

Canvassing will be a disqualification.

HUGH ROYLE, Town Clerk.

City and Port of Plymouth.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered Medical Men for the post of whole-time Assistant Medical Officer of Health to the City and Port of Plymouth. The chief duty of the officer will be to act as Port Medical Officer.

Applicants should not be more than 35 years of age.

The salary will be at the rate of £750 per annum, rising by annual increments of £50 to £900 per annum, and the appointment will be terminable by three months' notice on either side.

The possession of a Diploma in Public Health, or in Tropical Medicine, or a qualification in State Medicine, will be considered an advantage.

The person appointed will be required from time to time to assist in the general Public Health work of the City, and in the various Sub-Departments of the Public Health Department. He will act under the general supervision of the Medical Officer of Heath, and carry out any duties delegated to him from time to time.

Forms of application are not provided, and applicants should send a statement of their professional qualifications and experience, together with copies of not more than three recent testimonials, to the undersigned on or before Saturday, May 10th. Envelopes must be endorsed "Assistant Medical Officer of Health."

Canvassing will disqualify the applicant.

A. T. NANKIVELL, M.D., D.P.H., Medical Officer of Health, City and Port of Plymouth.

Town Hall, Stonehouse.
April 17th, 1930.

County Borough of Preston.

THE PRESTON INSTITUTION, FULWOOD.

Applications are invited for the post of JUNIOR RESIDENT MEDICAL OFFICER. Salary at the rate of £104 per annum, with board, lodging, etc. Candidates must be duly qualified and registered under the Medical Acts.

The appointment is for six months commencing on June 1st.

Duties include work in any wards of the Hospital in the Institution as required, and also in the Sharoe Green Maternity Home adjoining.

Applications, endorsed "Junior Medical Officer," should be made by letter, accompanied by copies of three testimonials of recent date, and should reach me on or before noon on Thursday, May 15th.

Town Hall, Preston.
Thursday, May 15th.

ALFRED HOWARTH, Town Clerk.

Newcastle-upon-Tyne Eye HOSPITAL.

Wanted immediately, JUNIOR HOUSE SURGEON, non-resident. Salary £150 per annum, lunch provided. Apply, stating age, qualifications, and Ophthalmic experience, with copies of testimonials, to the Secretary.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place,

Tele. Address: Triform, Wesdo—London. Oxford Street, W.1. Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Suitable house, with 3 reception, 4—5 bedrooms, bathroom, etc. One acre of garden. Price £900. Good sport and schools within reach. Premium 1½ years' purchase. Cottage Hospital.
9. SUSSEX.—Unopposed Village PRACTICE, old-established, in delightful surroundings, producing about £1,100 p.a., including panel of 545 and capable of considerable increase. Exceptionally charming residence, standing in 3½ acres of well-laid-out garden, tennis court, etc., and containing lounge hall, 2 reception, 7 bedrooms (3 fitted h. and c. water basins), dressing and 2 bathrooms, etc. Central heating. Electric light. Garage. Price for Practice and house £5,000.
10. MANCHESTER.—PRACTICE is situated in a growing district offering very large scope. Income about £1,700 p.a., including panel producing £450. Fees 3/6 upwards. Excellent detached house, well situated, with 3 reception, 5 bedrooms, etc., all in good order. Price £1,800. Premium 1½ years' purchase.
11. HANTS.—COUNTRY PRACTICE.—Very old-established, situated in most attractive district near Sussex Border. Receipts average over £800 p.a. Panel of 480. Detached house in half an acre of garden, 2 reception, 5 bedrooms, etc. Rent £55 p.a. Hunting, golf, etc., and first-class schools within reach. Premium £1,300.
12. LONDON, EAST.—PARTNERSHIP.—A one-half share is for disposal in an old-established chiefly working-class and panel Practice, averaging about £2,800 p.a. Panel of 3,600. Visits 2/6 to 5/6. Very suitable small house, with 3 bedrooms, bathroom, etc. Garden. Rent on lease £50 p.a. Premium £2,500.
13. KENT.—Within 40 miles of London.—In a town of 100,000, a well-established middle and working-class PRACTICE, worth last year £850, including panel of 200. Visits 3/6 upwards. Mids. from 3 gns. (20 cases yearly). House, with good accommodation. Rent on lease (15 years to run) £65 p.a. Premium £1,200. Practice equally suitable for Medical Man.
14. LONDON, SOUTH-WEST.—Very old-established non-residential PRACTICE, averaging about £4,000 p.a. Panel of 1,500, but large scope for more. Fees 2/6 upwards. Suitable house or flat can easily be obtained to meet purchaser's requirements. Rent of surgery on long lease £100 p.a. Premium 1½ years' purchase.
15. YORKS.—In a clean and thriving manufacturing town, an old-established Homœopathic and partly Allopathic PRACTICE, held about 50 years by Vendor who is retiring. Cash receipts for the past three years average £2,400 p.a. Patients middle and better class. Midwifery refused. Good house available, rent £100 p.a. Premium only one year's purchase, part down and balance by arrangement.
16. SURREY.—Attractive residential district within 20 miles.—Mixed-class PRACTICE producing about £700 p.a., but capable of much increase, as neighbourhood is developing. Panel of 500. Fees 2/6 upwards. Very nice house, with 3 reception, 3 bedrooms, and three acres of garden. Rent on lease £165 p.a. Smaller house available if desired. *Premium £1,200.*
17. LANCS.—LARGE TOWN.—Very old-established good industrial class PRACTICE, producing £2,500 p.a., including panel of 1,804, and assets worth about £120 p.a. Fees 2/6 upwards. Very suitable for two friends in partnership, as two houses available. Good sport and schools. Premium 1½ years' purchase. A one-half share will be offered with view to succession in six or twelve months if desired.
18. SOUTH OF ENGLAND.—LARGE SEAPORT TOWN.—Old-established mixed general PRACTICE. Average income nearly £1,900. Panel of 2,500. Fees 2/6 to 7/-. No mids. No Assistant kept. Well-situated house, with good accommodation. Rent on lease £120. Prem. £3,300.
19. *WITHIN* 40 MILES OF LONDON.—In a thriving Riverside and Hospital town (pop. over 40,000).—Old-established mixed-class and increasing PRACTICE worth over £2,500 last year, including panel of 1,600 to 1,700. House contains professional accommodation, 2 reception, 4 bedrooms, bathroom, etc. Small garden and garage. Rent on lease £60 p.a. Premium £3,650, to include good book debts of £500, drugs, etc., and consulting room and surgery furniture.
20. BORDERS OF BERKS AND HANTS.—In a delightful district, an old-established mixed-class PRACTICE averaging for the past three years £904 p.a. (last year £973), including panel of 400. Visits 5/- to 12/6, medicine extra (3/6). Very little midwifery. One opponent. House contains ample accommodation (2 sitting rooms, 7 bedrooms, bathroom, etc.). Large garden and garage. Water laid on and gas plant installed. Rent £50 p.a. Premium £1,400. Excellent sport.
21. PARTNERSHIP.—WEST MIDLANDS.—The Third share (with increase to half in 4 years and eventual succession if desired) is offered in very old-established mixed-class Practice in small town, largely residential, in midst of agricultural district of exceptional beauty. Cash receipts average £2,367 p.a., including panel of 1,084. Opposition not strong. Expenses light. Choice of two houses (small) which can be bought for £600 or £700. Premium 2 years' purchase.
22. *SURREY.*—In a beautiful residential district within 40 miles of London (good train service) a small mixed-class PRACTICE worth about £600 p.a. and offering scope. Select panel of 200. Charming house with ample accommodation in very pretty grounds (tennis court, etc.) of 1¼ acres. Price, freehold, £3,500. Premium 1½ years' purchase.
23. SOUTH-WEST OF ENGLAND.—Old-established and increasing PRACTICE in pretty district 5 miles from Hospital town and within 10 miles of the sea. Income last year £1,489, including Union, etc. (£105) and panel of 780. Railway station near. Detached house (professional rooms, 2 reception, 5 bedrooms, bathroom, etc.). Garden. Garage. Rent on lease £45 p.a. Premium £2,100.
24. WITHIN *FIFTY MILES OF LONDON.*—In a pretty residential district, a well-established PRACTICE averaging over £700 p.a., including panel of 538, and appts. worth about £60. Visits 5/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (3 reception, 5 bedrooms, etc.), with large garden, tennis court. Garage. Elec. light. Price for freehold £3,000. Premium £1,050. Exceptionally good educational facilities for boys.
25. LARGE UNIVERSITY CITY (WEST).—Good-class old-established non-dispensing PRACTICE worth last year £1,274, including select panel of about 350. Visits up to 21/-. Very little midwifery. Good house in best part of City, overlooking park, with ample accommodation. Vendor's freehold, but will be let on lease. Premium only £1,200.
26. PARTNERSHIP.—In a most desirable outlying residential suburb a suitable Partner (University Graduate, Oxon. or Cambs., experienced, 30 to 35 years of age and married preferred) can acquire a share (producing at first about £1,200 p.a., but larger might be considered, with further shares up to a third at arranged intervals) in an old-established good mixed-class Practice, averaging over £10,000 p.a. Very good house, with ample accommodation, garden, etc., on rental. Premium 2 years' purchase. Short preliminary assistantship essential.
27. YORKS.—LARGE TOWN.—Very old-established middle and working-class PRACTICE, offering exceptional scope for increase. Income for last year £1,500, including panel of over 1,700. Visits 4/6 to 5/-. Conveniently situated house, with 2 reception, 4 bedrooms, etc. Rent on lease £56 p.a. Premium £2,250.
28. PARTNERSHIP.—OXON.—Delightful residential district, near good town.—A one-third share (to commence with) in an old-established good mixed-class Practice, averaging for the past three years £1,540, and offering good scope. Panel of nearly 1,000. Fees 3/6 to 21/-. Choice of two houses at rentals of £100 and £50 p.a. Sport of all kinds. Premium 1 year's purchase.
29. LONDON, S.W.—Old-established middle-class PRACTICE, producing over £1,000 p.a., including small panel of 580. Fees 2/6 to 7/6. Mid. lately refused. Good corner house, with ample accommodation. Rent on lease £115 p.a. Premium 1 year's purchase.
30. MANCHESTER DISTRICT.—Old-established middle and working-class PRACTICE, worth last year about £700, including panel of 590, and capable of increase. Expenses small. Well-situated house, with 6 rooms in addition to professional rooms. Large garden. Price, freehold, £850. Moderate premium accepted.
31. NOTTINGHAM.—Old-established good middle and working-class PRACTICE. Income from panel nearly £700 and large scope for general practice. Good well-situated house. Rent on lease £80. Premium £1,200, payable £600 cash and balance by instalments.
32. SOUTH-WEST OF ENGLAND.—POPULAR COAST TOWN.—A one-third share in an old-established PRACTICE, having good surgical scope. Gross cash receipts average £4,200. Panel of 1,800. Suitable house available, on rental. Premium £2,250.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

NATURALLY RICH

IN VITAMIN "D"

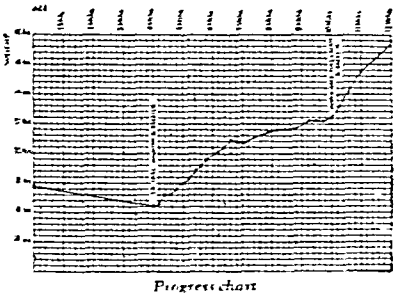
A "RESURRECTION"

THE mother of Baby "H" wrote to our Motherhood Bureau when he was 4 months' old (weight only 6 lbs. 9 ozs.) suffering from Marasmus following Whooping Cough complicated by Double Pneumonia. The infant was put on to LACIDAC (Separated) with a small quantity of BRESTOL and immediately made steady progress.

"At 6 months he had gained 3 lbs. 7 ozs. and by the end of another 4 months his weight was 12 lbs. 6 ozs., and progress was so good that it was possib e to change him gradually on to Cow & Gate Full Cream and Brestol.

"He has now cut teeth quite successfully and at the age of 10 months is taking normally to mixed feeding and is a happy, lively baby.

"His Doctor considers him a '*Resurrection.*'"



The original of the above letter may be inspected at our head office in Guildford.

AFTER—6 months' old, 10 lb. in weight

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight

COW & GATE LTD. GUILDFORD, SURREY

HORMOTONE
BRAND
for
PREMATURE SENILITY
and
OLD AGE

Stimulates metabolism
Increases muscle tonicity
Raises respiratory exchange
Effects marked subjective improvement

"Old age being caused by degeneration of the endocrine glands, especially the thyroid and sexual glands, all that is necessary to secure rejuvenation is to improve the condition of these glands. The best and easiest way to do this is to administer by the mouth extracts of these glands after their extirpation from healthy animals. . . .

"The persons treated looked considerably younger after it, to the extent of ten or fifteen years, and sometimes even more. The wrinkles in the face already began to disappear four or five weeks after the treatment, and, at the same time, previously corpulent persons, losing their excess of fat, were made to look slender, thus imparting a youthful impression."

(Lorand, "Life Shortening Habits and Rejuvenation," 1922.)

Dose: 1 or 2 tablets three times daily.

Viosterol "A. & H."

Irradiated Ergosterol *(Vitamin D)* in Oil

Biologically Standardised

Viosterol "A. & H." is standardised to contain 10,000 units of Vitamin D in each c.c., i.e., it possesses 100 times the Vitamin D activity of good Cod-Liver Oil.

Viosterol "A. & H." is the specific treatment for rickets, tetany and other disturbances of the calcium-phosphorus metabolism.

Special advantages of Viosterol are the small dosage required, its prompt effect, palatability and absence of digestive disturbances.

Viosterol "A. & H." is issued in special rod-stoppered bottles containing 5 c.c. and 50 c.c.

Special literature on request.

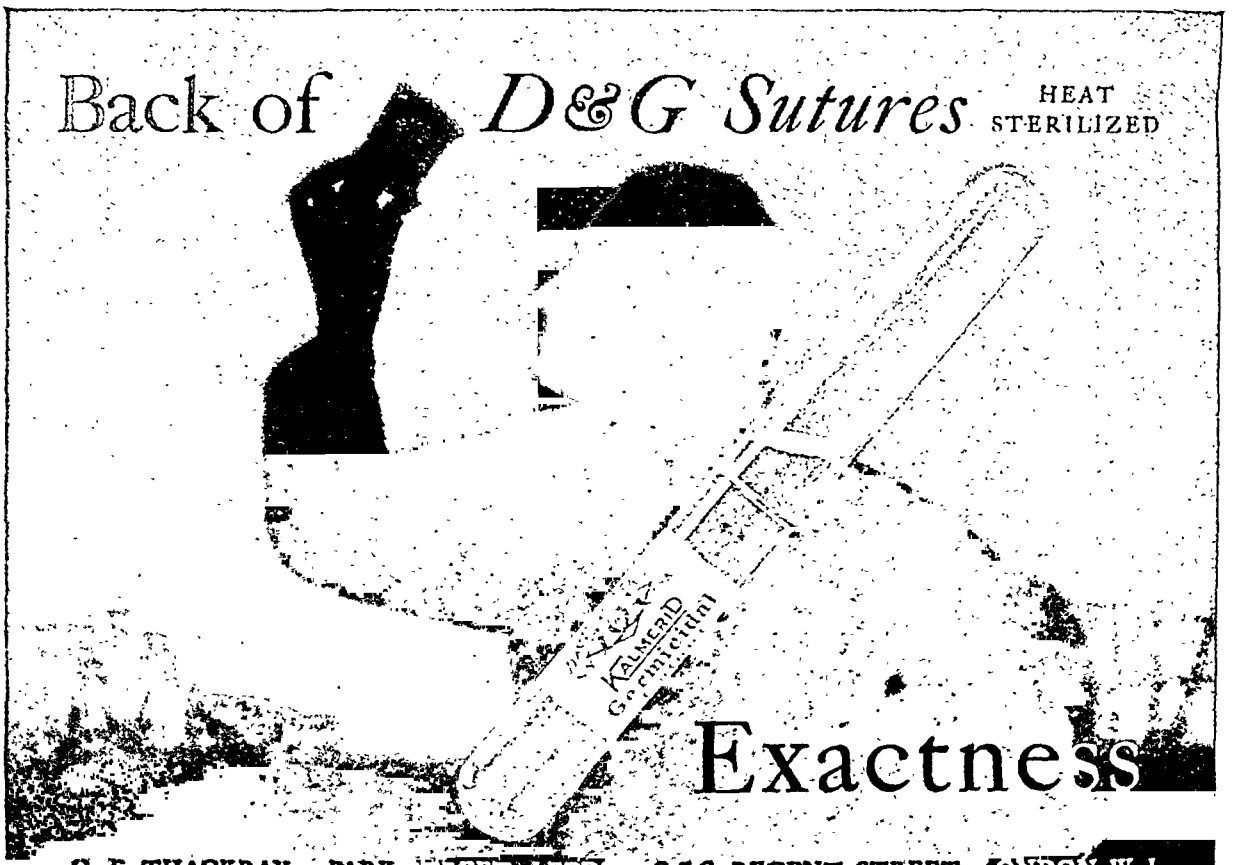
The Therapeutic value of BRANDY–

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers. These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience.

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.

Cognac Brandy alone provides them.



Take no risks;
ensure the results you expect

Prescribe Brandy distilled in Pot Stills from Wines grown in the best Cognac districts; Matured in warehouses which have been filled with Cognac Brandy for centuries; Made by Men with the inherited Experience of Seven Generations.

In short—Prescribe
MARTELL'S BRANDY

and know *that you are doing the best possible for your patients.*

THE CLINICAL PATHOLOGY OF THORACIC PUNCTURE FLUIDS.
By S. ROODHOUSE GLOYNE, M.D., D.P.H., Pathologist, City of London Hospital for Diseases of the Heart and Lungs, Victoria Park.
10s. 6d. net, post free 11s.
This book is an attempt to bring together information on a subject which is apt to be neglected because it lies between the domain of the clinician and the pathologist. The growing importance of operative treatment in chronic lung disease increases the importance of the subject year by year. The book gives technical details for laboratory examination, and gives a description of the various types of pleural fluids. **It is the only book devoted entirely to this subject.**

A MANUAL OF TROPICAL DISEASE AND HYGIENE FOR MISSIONARIES. 2nd Ed. Revised. Edited by EDWIN A. NEATBY, M.D., and T. MILLER NEATBY, M.A., M.D. With Forewords by Sir Aldo Castellani, K.C.M.G., M.D., F.R.C.P., and Sir James Cantlie, K.B.E. Illustrated by 20 Plates (14 coloured) and 118 Figures and Charts.
INDISPENSABLE TO EVERY MISSIONARY.
A book giving invaluable information to a Missionary when away from medical aid. Over 600 pages of helpful matter for preserving the health and dealing with sickness in the Tropics, for the small cost of 12s. 6d. net, post free inland 13s. 3d., abroad 14s.

SEX AND ITS MYSTERIES. By GEORGE RYLEY SCOTT.
10s. 6d. net, post free 11s.
"A book of considerable merit. . . . Covers the ground of a somewhat difficult subject very completely, and its publication will do much to clear away many misunderstandings which have crept into our social life on sexual matters owing to lack of a proper knowledge concerning them."—*Medical World.*

THE IMMUNOLOGY OF PARASITIC INFECTIONS. By WILLIAM H. TALIAFERRO, Ph.D., Professor of Parasitology, University of Chicago. Illustrated. **25s. net, postfree inland 25s. 9d. net, abroad 26s. 6d.**
"An important contribution to medical literature and one which should focus the attention of tropical workers in particular on the deficiencies and gaps in present knowledge of this important subject."—*Lancet.*

WORK CENTRES FOR THE TUBERCULOUS. **The Experience of the Spero Firewood Factory, London.** By NOEL DEAN BARDSWELL, M.V.O., Legion d'Honneur, M.D., F.R.C.P., F.R.S.Edin. **3s. 6d. net, post free 3s. 9d.**

BRITISH MEDICAL ASSOCIATION HOUSE, TAVISTOCK SQUARE, W.C.1.

Doctors have proved its worth

SIR HENRY THOMPSON, the eminent surgeon, in his treatise on "Food and Feeding" said:—

"For those who can afford to buy bottled waters, no purer exists in any natural source than that of our own MALVERN SPRINGS. Certainly, it is wholly unnecessary to import waters for the use of the table from foreign sources.

No foreign waters of any kind whatsoever are so pure or so cheap."

Obtainable at all leading hotels, wine merchants, chemists and stores.

Head Office:
1, Connaught Place, W.2.

MALVERN WATER

THE PUREST SPRING WATER

PERMANENT ALL SICKNESS AND ACCIDENT INSURANCE FOR MEDICAL MEN AT THE LOWEST RATES

The following specimen rates show the cost of each guinea per week payable during total incapacity arising from any form of Sickness or Accident, except those due to the wilful misconduct of the insured.

The full sum insured is payable for the first 26 weeks, and thereafter half that amount so long as the total incapacity lasts, up to the age of 65.

AGE 25, £1 : 12 : 8	AGE 35, £2 : 1 : 0
,, 30, £1 : 16 : 5	,, 40, £2 : 6 : 7

A Reversionary Bonus of 15/- per guinea per annum was declared on these Policies at the last valuation.

SICKNESS FUND exceeds £370,000

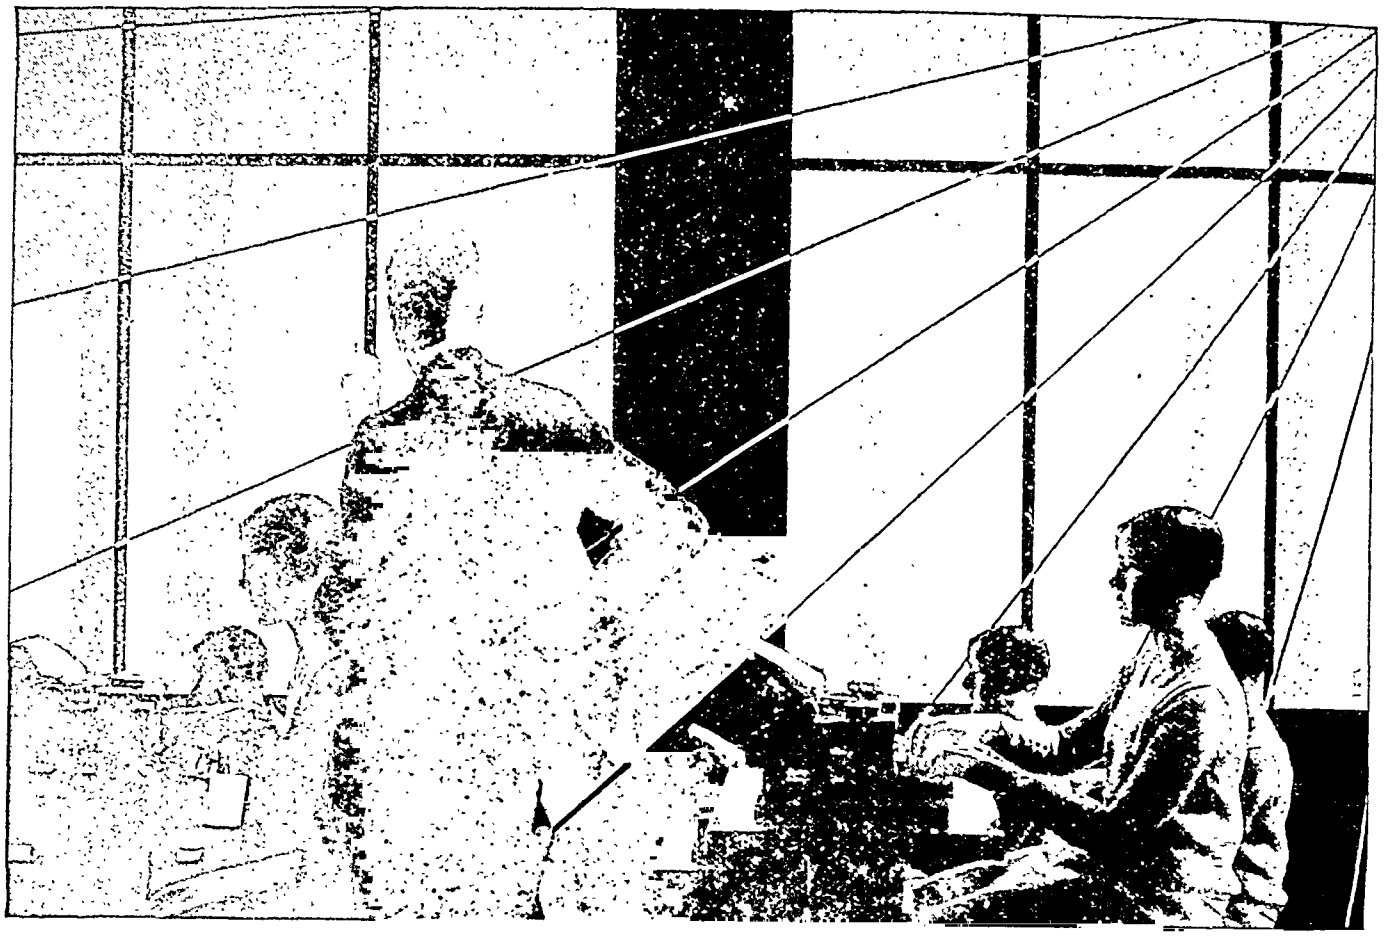
CHOOSE YOUR CAR

WE BUY IT BACK

We have a plan that enables you to write off car ownership as professional expenses. It is called the Guaranteed Repurchase Plan and this is how it works.

You choose the kind of car you want, any make, any type. Before you buy, we guarantee in writing to repurchase the car you choose at an agreed price after an agreed period. As soon as the purchase is completed, the car is absolutely your property until you wish to resell. There are no inspections, no irksome conditions and no restrictions as to mileage.



This plan is far cheaper than hiring and much more convenient. You enjoy the full pleasure of ownership with no risk of disproportionate loss at resale, and you may have a new car at such intervals as are most convenient to you.

Let us send you a booklet describing this plan in detail. This book shows how simple and how practical this plan is and the number of people who have taken advantage of it.

"COME IN, COME IN!"

Slowly the facts emerge after years of doubt. Now we can say, with proof ready at hand, that the health rays are present in outdoor light on fine days, dull days, wet days, and sometimes even on foggy days.

The National Physical Laboratory is making an investigation to show the wave-lengths of the ultra-violet rays detected daily throughout the year July 1929/1930. An interim report covering July to the end of November has been published. Certain weather conditions such as snowstorms and thick yellow fog have yet been recorded, but every day up to the full of November wave-lengths well down as long as the th band have been detected. The des all wet days, days with overcast skies and even one day on which there was "a fairly thick white fog."

These rays must not be wasted. They can be brought indoors through "Vita" Glass windows at a very small extra cost now that the prices of "Vita" Glass have been reduced. It is an actual fact that there is more of the valuable ultra-violet light in a room fitted with "Vita" Glass on a dull November day than in a room fitted with ordinary window glass on the brightest day in summer.

Write for a copy of the National Physical Laboratory's report and full particulars of "Vita" Glass to the "Vita" Glass Marketing Board, 9, Crown Glass Works, St. Helens, Lancashire.

Alimentary Toxæmia and Neurasthenia

NEURASTHENIA is no doubt a comprehensive term which includes several affections of different ætiology

In many of the cases alimentary toxæmia plays a considerable part; the digestion is upset and flatulence is frequent, the bowels are fickle in their action, and the indican and ethereal sulphates in the urine are markedly increased—sure signs of putrefactive changes in the bowel.

Intestinal Disinfection

In this class of cases intestinal disinfection is one of the principal lines of treatment to be adopted, and for this purpose nothing surpasses the use of Kerol Capsules

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol One to three capsules may be given three or four times a day after meals.

Kerol Capsules

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

0·20 gm. 0·60 gm.
Supplied in Sterile Solution, in Ampoules READY FOR USE.

IODINE THERAPY

IODOLAIT

(DUNCAN)

A palatable, pleasantly flavoured preparation containing an Iodo-protein compound equivalent to 2 grains of Iodine in each ounce.

Duncan

It is well tolerated, and, as it contains no Alkali Iodides, it is less liable to give rise to symptoms of Iodism.

Indicated in Arthritis, Chronic Gout, etc.

Sample and price on application.

DUNCAN, FLOCKHART & CO.

EDINBURGH and LONDON

104, Holyrood Road. 155, Farringdon Road, E.C.1.

KAYLENE-OL

An evacuant and adsorbent emulsoid of Kaylene and Colonol Liquid Paraffin forming, with the residues, a soft homogeneous mass which slips easily past the bends and kinks of the colon with a minimum of friction and delay.

It restores the normal responsiveness of the mucosa, establishes a habit of regular defæcation, and is indicated for conditions in which toxæmia is suspected as a contributory cause.

KAYLENE-OL ADSORBS AND ELIMINATES
INTESTINAL TOXINS.

Patients unable to take liquid paraffin or paraffin emulsions find Kaylene-ol easy of assimilation.

Samples and "Adsorption" literature obtainable on request to the manufacturers:

Kaylene Ltd

7, MANDEVILLE PLACE,
LONDON, W.1.

Telephone: WELBECK 3555. *Telegrams*: "KAYLOIDOL, WESDO, LONDON."

THE FRENCH NATURAL MINERAL WATER

VICHY-CELESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

INDICATIONS.

GASTRIC.

PRIMARY DYSPEPSIAS:
- Hyperpepsia—Intermittent hyperchlorhydria.
- Hypopepsia and apepsia—Dyspepsia arising from disturbance of neuro-motility.
- Intermittent pyloric stenosis, not of organic origin.

SECONDARY DYSPEPSIAS:
- Arthritic dyspepsia.
- Toxic dyspepsia (gastro-hepatic).
- Dyspepsia due to enteroptosis.

HEPATIC.

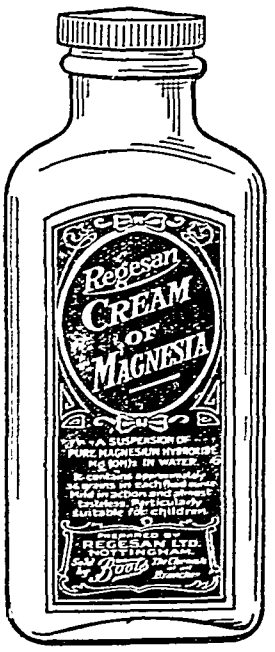
- Congestion due to excessive or improper feeding.
- Congestion due to cirrhosis (before the cachectic stage).
- The diathetic congestions of diabetic, gouty, and obese persons.
- Congestion due to poisoning (mercury, morphine, etc.).
- Toxic congestion (influenza, typhoid fever, etc.).
- Biliary lithiasis.

MALARIA AND TROPICAL DISEASES.

DIATHESIS.

The diabetes of fat people. Arthritic obesity. Uricæmia and gout. Rheumatic gout.

URINARY GRAVEL.



CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

INGRAM & ROYLE, LIMITED,

Bangor Wharf, 45, Belvedere Road - - - - - - - London, S.E.1

and at LIVERPOOL and BRISTOL.

Samples free to Members of the Medical Profession.

Regesan

CREAM OF MAGNESIA

A pure, finely divided Magnesium Hydroxide ($Mg(OH)_2$) suspended in water. A simple antacid and valuable laxative. Digestive troubles and gastric conditions indicating the necessity of a corrective of this type quickly respond to treatment with Regesan Cream of Magnesia.
It does not gripe nor cause discomfort, and is mild in action.

Price 1/3 per bottle.

Full size trial sample free to Medical Practitioners in the British Isles on application to Boots The Chemists, Station Street, Nottingham.

WHEN SOLID FOODS CANNOT BE TAKEN THESE ESSENCES

STIMULATE AND RESTORE VITALITY RAPIDLY

BY APPOINTMENT

THE value of Brand's Essences in illness and convalescence is recognized by an overwhelming majority of modern doctors. Out of *every* 100 *recently interviewed* 99 prescribed this famous product for their patients.

Brand's Essences are the unadulterated juices of the finest freshly killed meats conserved by a unique process in their natural form—a clear, appetizing jelly. They contain no added substance such as colouring matter, gelatine or preservatives which could hinder assimilation. Their effect on the gastric juices is immediate—they stimulate these secretions to instant activity.

During acute illness—particularly pneumonia or gastric disorders—they form an invaluable restorative through those periods when the system is incapable of digesting solid food.

And in convalescence, Brand's Essences excite appetite—overcome that reluctance to eat so apparent after nearly every dangerous illness.

Brand's Essences can be obtained at chemists and stores throughout the world in tins and glasses. On receipt of a professional card, trial samples will be sent to you. Write Dept. F4. Brand & Co. Ltd., Mayfair Works, Vauxhall, S.W.8.

OUT OF EVERY 100 DOCTORS RECENTLY INTERVIEWED 99 RECOMMEND

BRAND'S ESSENCES

(Made only from the finest English Beef, Chicken or Mutton)

ANTISEPTICS and DRAINAGE in INTESTINAL TOXAEMIAS

"I always insist upon the bowels being open before the administration of Dimol. The best results cannot be expected in a LOADED GUT, even from four Dimol pulverettes or tablets (the bactericidal equivalent of 140 grains pure carbolic). Flush the bowel, to remove mechanically as much as possible, then administer Dimol, when its powerful bactericidal action will be brought to bear with the greatest effect on the putrefactive organisms still lining the mucosa in their teeming millions, ready to set up the same disturbance with the next meal." ———M.D.

FOR over nine years Dimol has given universal satisfaction as the most potent non-toxic bactericide available for disease associated with an intestinal focus, and it is only because we have recently had our attention drawn to a few uneven results obtained in some cases of bowel stasis that we suggest the advice given above should be followed before the administration of the **full doses** recommended, i.e., not less than three or four pulverettes or tablets thrice daily.

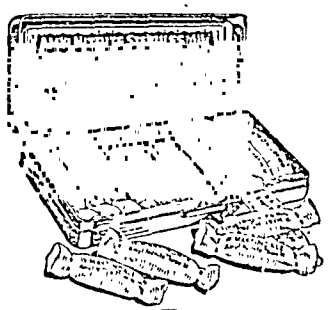
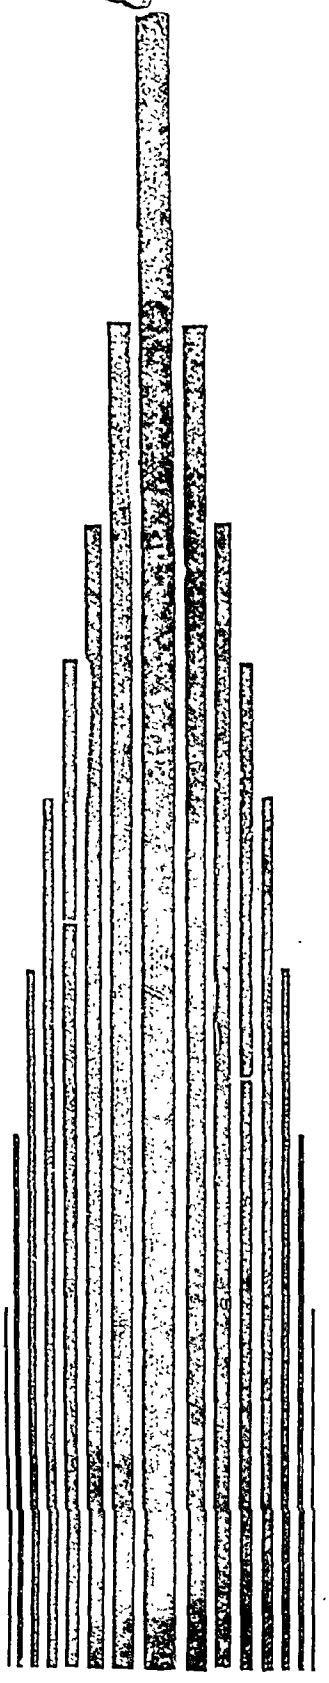
RADIOSTOLEUM

Radiostoleum is a potent solution in oil of Vitamins A and D; it is biologically standardised to a Vitamin A activity 20 times that of a high grade cod liver oil and to a Vitamin D activity 100 times that of a high grade cod liver oil.

Radiostoleum acts as a definite anti-infective, prophylactically, in building up resistance against infection, and therapeutically, in the treatment of actual cases of acute infections.



Further, Radiostoleum promotes healthy growth and checks dental caries. It possesses outstanding advantages over cod liver oil resulting from its high concentration—and consequent small dosage—and from its uniform activity.



Radiostoleum administration, on account of the fact that it produces no gastric disturbances and on account of its certainty in therapeutic effect, has become the routine treatment for all conditions arising from Vitamin A and Vitamin D deficiency; in fact, in all such conditions in which cod liver oil was used hitherto, Radiostoleum can now be used with distinct advantage.

AMYL NITRITE "STERULES"

(MARTINDALE—Regtd. T.M. & Design)

IN BOXES OF 12 "STERULES"

Containing 1, 2, 3, 4, 5, 6, or 10 minims (0.05, 0.1, 0.2, 0.25, 0.3, 0.33, or 0.6 c.c. approx.), the usual dose being 3 minims (0.2 c.c.).

For relieving ANGINA PECTORIS, SPASMODIC ASTHMA, MIGRAINE, POST-PARTUM HAEMORRHAGE, HAEMOPTYSIS, SEA-SICKNESS, to ward off EPILEPTIC ATTACKS, etc., and as an ANTIDOTE to CHLOROFORM; it is largely employed in threatened FAINTING and COLLAPSE, and as a RESTORATIVE after GAS in DENTAL OPERATIONS.

Abstracts from the medical literature:

ANGINA PECTORIS: "The best remedy. To lower blood pressure has a more rapid action than any other drug, and is useful in cutting short the paroxysms of pain." —L., ii/05, 325; ii/06, 1335.
"Gave prompt relief in the more pronounced attacks." —B.M.J., ii/06, 304.
"In all spasmodic affections, such as angina pectoris, one of the best remedies."—B.M.J., i/09, 994.
"The nitrites are indispensable."—B.M.J., ii/09, 1122.
"The quickest means of relieving the acute pains." —L., ii/08, 1132.
"Fear of death entirely disappeared."—L., ii/09, 572.
"No drug can compare with Amyl Nitrite."—L., i/09, 240; L., ii/05, 812.

INTRATHORACIC ANEURISM: "For the acute anginal attacks Amyl Nitrite inhalation, followed by internal use of Nitroglycerin or Erythrol Nitrate, is generally efficacious."—L., i/13, 948.

ASTHMA: "In most cases the reduction in blood pressure relieves."—B.M.J., ii/11, 1327.

POST-PARTUM HAEMORRHAGE: "Immediately stopped; no further trouble followed."—B.M.J., ii/06, 1125.

HAEMOPTYSIS: "With few exceptions, promptly effective. Secures peace of mind to sufferers." —L., i/08, 130.
"Some convincing cases in which it saved life." —L., i/07, 939.
"Amyl Nitrite the drug par excellence; acts better the quicker it is used."—Edin. Med. Jl., 1904; L., ii/04, 522, 942, 1446; B.M.J.E., i/06, 79.
"In severe haemoptysis—rupture of an atheromatous pulmonary vessel—free use satisfactory."—B.M.J., i/06, 917.

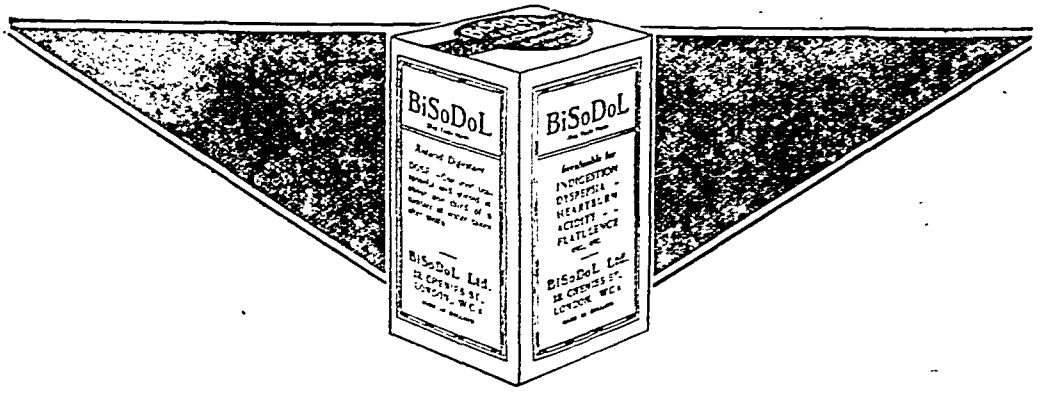
SEA-SICKNESS: Very useful; inhalation repeated every 2 or 3 hours if necessary.

CHLOROFORM SYNCOPE: The quickest means of restoring the heart's action.

INFANTILE CONVULSIONS: Well treated by 1 mm. "Sterule."

PLEASE SPECIFY MARTINDALE'S AMYL NITRITE "STERULES"

We also supply other vasodilators, e.g.:



MANNITOL NITRATE TABLETS: 1 gr.

ERYTHROL NITRATE TABLETS: ¼, ½, and 1 gr.

An Effective Antacid and Digestant

The Physician is constantly called upon to prescribe for digestive disturbances. In the treatment of such cases, BiSoDoL will be found a reliable preparation.

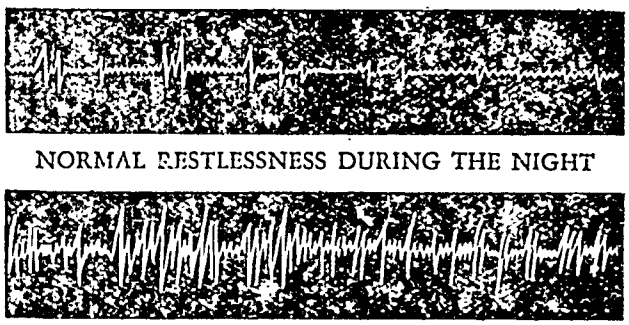
BiSoDoL is a balanced formula presenting in suitable proportions the bases Sodium and Magnesium, with Bismuth Subnitrate, Carica Papaya, Malt Diastase and Mentha Piperita.

BiSoDoL is agreeable to the Patient and no unpleasant symptoms follow its administration.

BiSoDoL is quickly effective. Beneficial results have been especially marked in cases of impaired digestion, and in the control of cyclic vomiting, and the morning sickness of pregnancy.

BiSoDoL

Samples will be gladly sent to Physicians on request.



BiSoDoL Limited,
12, Chenies Street, London, W.C. 1.

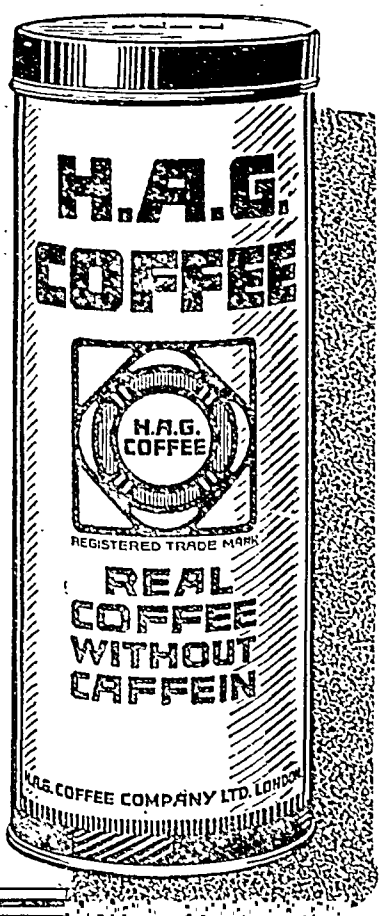
For neural patients

DELICIOUS

H.A.G. COFFEE

— 97% DECAFFEINIZED

NORMAL RESTLESSNESS DURING THE NIGHT



INCREASED RESTLESSNESS RESULTING FROM INDIGESTION OF CAFFEIN

CAFFEIN is never prescribed for neurasthenia, hysterical, insomnious or psychopathic patients. It is too well known how this drug shortens reaction time, excites the reflex arch of the spinal cord, and stimulates the nervous system generally, as shown on the chart at the right.

This is why coffee is forbidden is such cases. But it is not necessary to make this usually vain attempt to change the habits of coffee drinkers. Instead of saying "Stop coffee" simply say "Drink H.A G. Coffee." H.A.G. Coffee causes practically no increase in nervous stimulation, as the illustration above indicates.

Price per 6 oz. tin 1/4, either berry or ground.

Special 5 lb. tin for Medical Profession 13/6.

NOT A SUBSTITUTE

H.A.G. COFFEE, although 97% decaffeinized, is not a substitute It is blend of the choicest Central American and South American coffee berries, combined in just the right proportion to give that tasty fragrance and flavour found only in coffees of the highest grade Its taste is not impaired in. the slightest because the caffein is extracted from the raw beans—before they are roasted.

H.A G. Coffee is the same coffee as the coffee known on the Continent as "Kaffee HAG" and in America as "SANKA COFFEE." It is very highly recommended by the Medical Profession abroad and practically no other coffee is consumed in such health resorts as Bad Nauheim, Carlsbad, etc., etc.

A TRIAL TIN WILL ALSO CONVINCE YOU

Obtain a liberal sample by sending in the attached coupon to-day.

H.A.G. COFFEE COMPANY, Ltd.,
40, Theobald's Road, London, W.C.1.

Please send me free of charge a liberal sample of H.A.G. Coffee—also the booklet "Some Observations of the Action of Caffeine."

COW & GATE LTD. GUILDFORD, SURREY

The most efficient Peptonising Powders!

Half a tube of Benger's is enough!

While half a tube of Benger's Peptonising Powders is enough to peptonise a pint of milk, gruel or soup, in most cases in 10 minutes, the extent of the peptonising action can be regulated by either increasing or diminishing the quantity of the powders, and by lengthening or shortening the time during which they are allowed to act on the milk, gruel, etc.

Generally speaking, Benger's Peptonising Powders produce the required result with half the quantity necessary of other preparations, whose initial cost also is higher.

Prices:
No. 1—Box of 6, 1/-; No. 2—Box of 12, 1/8

Benger's Liquor Pancreaticus.

An important aid in the preparation of Peptonised Milk, etc.

Benger's Liquor Pancreaticus is an active solution of the digestive principles of the Pancreas; a really efficient agent for the digestion of milk, gruel, and farinaceous or partly farinaceous foods. Benger's Liquor Pancreaticus is odourless and tasteless.

In 4, 8 and 16-oz. bottles.

Prices: 3/-, 5/6 and 10/6

Medical men may obtain full particulars of Benger's preparations post free on request.

REPRESENTATION OF THE EMPRESS THEODORA AND HER COURT.—Constantinople had already created and disseminated Christian traditions, and conditions of unexampled luxury developed, thus producing the paradox of a people steeped in material well-being, yet professing a religion which was purely spiritual. The Byzantines pioneered their way to the forefront of civilisation by the end of the sixth century and maintained this position for a thousand years; but, from the point of view of ethics, their superiority was one chiefly of externals, especially in Constantinople. Society, as a whole, was corrupt and decadent. The accompanying illustration may be taken to typify the degree of civilisation in externals to which the Byzantines attained. The scene is dignified, stately, hieratic. An extreme decency in dress is combined with great richness and beauty of fabric. The Empress, offering gifts to the church, is approaching the sacred fountain, while a servitor raises for her the curtain hung before the door of the temple.

COPYRIGHT

VITAMINS A, B & D
HAVE ALWAYS BEEN IN CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

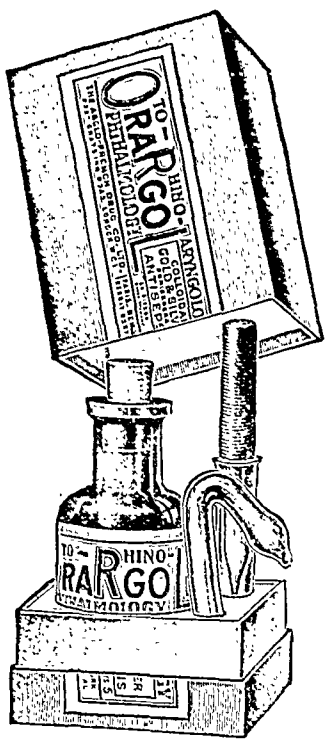
By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession — a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

FOR THE TREATMENT OF **HAY FEVER** CORYZA, CATARRH, etc.



KINECTINE

(Benzo-sulpho-para-amino-phenyl-arsenate of QUININE.)

Dose: One tablet three times a day. Half doses for children.
In Tubes of 10 Tablets.

ORARGOL COLLOIDAL GOLD & SILVER

In SPECIAL OUTFIT for RHINO-LARYNGOLOGY.

Dosage: 4-5 drops applied to each nostril (in the douche supplied) 3 or 4 times daily.

Dr. C. writes:—

"Congratulations on your Orargol. I have just rid myself in one day of severe coryza. This is not the first time I have had the same success, and you may rest assured that I will continue to prescribe this interesting speciality."

Remarks
ON
EARLY SIGNS OF CARDIAC FAILURE OF THE CONGESTIVE TYPE.*

BY
SIR THOMAS LEWIS, M.D., F.R.C.P., F.R.S.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

To the student of cardio-vascular disease the ability to form a broad estimate of the way in which the general circulation is carried on under various circumstances is of paramount importance. When a patient seeks advice, and disease of the heart is suspected or is present, one question should stand prominently in the foreground, namely, What is the capacity of the heart for work? The answer to this question dominates both prognosis and treatment to an extent that forces other considerations well into the background in most cases of chronic heart disease. Innumerable tests have been, and continue to be, devised to answer this question; they are based mainly upon pulse and blood pressure readings taken in various circumstances of posture, exercise, etc. One danger of these tests is that, as they are frequently presented by means of formulae, they are apt to create an impression of scientific accuracy that they are far from possessing. Experience of such tests has convinced me that they have little practical value, and, tending as they often do to becomes rules of thumb, they likewise become most undesirable. Recently, numerous attempts have been made to estimate cardiac output in terms of fluid volume; while these methods have a significance in physiology, they have as yet found no application in clinical work, and are unlikely to find such application for many years to come.

Cardiac capacity in patients is to be gauged rather by a close study of the symptoms arising out of exercise and by the early signs of congestion; by simple methods that can be grasped and applied by practitioners; methods which for these reasons, as well as for their proved worth, stand unrivalled in practical everyday work.

If, in speaking of heart failure, we are to include not only the terminal phenomena but also all the earlier manifestations that may be linked transitionally with them, then we shall review, if only briefly, the main results of cardiac muscle weakness in its different grades. It has been held, and not without justification, that cardiac failure can be of two distinct forms, namely, that manifesting itself chiefly by the well-known symptoms belonging to the anginal group, and that manifesting itself first in breathlessness, and continuing in its natural development to profound engorgement of the venous system. It is not proposed to cover all this ground, but to deal only with failure of the second type, a type that ends in what is often spoken of as "loss of compensation" or "decompensation," two terms which, in my view, should be abandoned, since, in so far as they retain their original meaning, they infer (and infer unnecessarily) far more than can be proved, and since they conceal the essence of the situation; I prefer and advocate the term "congestive failure."

When congestive failure develops gradually, the symptoms and signs of this condition come insidiously, and the order of their appearance is definite. The main symptom is breathlessness. All men and women, however athletic, become breathless on exercise: the first indication of cardiac failure of this type manifests itself in a limitation of the field of response; an active subject notices breathlessness or unusual breathlessness on undertaking some customary act of vigorous work. As this failure progresses, the same breathlessness continues to be experienced, but it is experienced in response to an amount of work that decreases as time passes. This progression may be more or less continuous, spread over months or years, or it may occur in definite steps: this latter is by far the commoner. In grading cardiac breathlessness I do so in the first instance, not by the degree of distress it occasions, but by the amount of physical effort that brings obvious breathlessness into being. Breathlessness occurs on walking quickly or uphill, on walking on the flat, on walking slowly short distances: later it begins to be present when at rest: these are the grades. *It is in the last two stages that the early signs of actual venous congestion appear, and as congestion increases, breathlessness at rest becomes more obvious and more distressing.* Thus the complete course from health to gross heart failure is displayed by the cardinal symptom, breathlessness, graded in its degree from normal breathlessness on active exertion to constant distress when the body rests completely. These grades of breathlessness are ascribed to various deficiencies in the flow of aerated blood through the brain: at first the deficiency is confined to those exercises in which normally the cardiac output is much above resting value; at last there is a deficiency in the physiological quantity of blood expelled by the heart while the body is at rest. It is then that blood begins to collect on the venous side and the patient begins to manifest signs of congested veins, and, associated with these, such signs as enlargement of the liver, cyanosis, a high-coloured scanty urine, ascites, dropsy of the lower members, and the signs of congested and oedematous lungs. Of paramount importance, however, are the signs in the veins: that is so because they are usually amongst the earliest that can be detected: for that reason every medical student should make a full study of them.

Direct measurement of venous pressure has been much used in my wards in past years, and gives in my experience a good idea, within its limits, of the patient's state; it presents, in repeated readings, clear indications of the patient's course. But it is obvious that this method cannot come into wide use, so for many years I have striven to displace it by simple bedside tests that may be applied by any thoughtful and good observer. In arriving at the clinical methods now used in my department, actual manometric determinations of venous pressure have formed important and frequent guides. After describing quite briefly the manometric method, and having illustrated the simple hydrostatic principles involved, the bedside signs that have been found of value will be discussed.

Measures of Venous Pressure.

To measure pressure in the veins more than one device has been employed. A simple piece of apparatus (after the original plan of Moritz) consists of a manometer connected to a wide needle by rubber tubing, the whole filled with a solution of sodium citrate to prevent clotting. The needle is driven into a vein, and the height at which the fluid comes to rest in the manometer measures the venous pressure in centimetres of citrate solution. This, broadly described, is a method of accuracy. A vertical measure, taken from the meniscus to the point at which the vein is punctured, tells the pressure *in the vein at that point.* The measure serves also as a gauge of pressure in the right auricle, provided that no local impediment to the stream exists in the venous stem between the point chosen and the right auricle, the veins being widely patent, and provided that the level of the venous point chosen relative to the heart is known. For if the vein chosen is in the arm, and the arm is raised, the pressure in that vein will fall, or if the arm is lowered it will rise, correspondingly. Since the position of the punctured point, relative to the general system of veins, will vary in different circumstances, it is customary to choose some standard point of reference, and the point we have chosen in patients lying supine is the lower border of the manubrium sterni. If the needle is passed into the median basilic vein of a normal subject so postured, the fluid column in the manometer will usually come to rest level with the sternum, or a few centimetres below, or, less commonly, a centimetre or two above it. Thus, if the punctured vein lies level with the sternum, the meniscus will come to rest at or about the level of the puncture, and, as the arm is depressed, it will not move appreciably relative to the sternum, but the column will

* The gist of a lecture delivered before the Portsmouth Division of the British Medical Association on December 23rd, 1929.

reach above the vein by the amount the arm is lowered (Fig. 1). The venous reservoir thus behaves much like a simple reservoir. In this the surface of fluid lies at a given level, and there the pressure is atmospheric or zero. In the depths of the reservoir pressure is greater, and it is greater by the amount of the vertical column of fluid that extends from any given point to the surface of the fluid.

We may speak of the zero (or atmospheric) pressure level of the fluid in the venous system in much the same sense, and that level is near the lower border of the manubrium sterni in normal subjects. This point of reference is chosen because it represents approximately the level of zero pressure whether the body is horizontal or vertical, or in any intermediate position. It is likewise true of the flaccid body that the pressure in veins lying at different levels below the sternum is greater, and at levels above the sternum is less, than atmospheric pressure. Thus, normally, all veins which lie higher than the manubrial point are collapsed, all which lie below it are distended. If, therefore, we can gauge the precise level at which the veins collapse we have a gauge of the filling of the venous reservoir and of general, or to be more exact of right auricular venous, pressure. A simple and old test of venous zero level is to watch the veins on the back of the hand or at the elbow. These, when the arm hangs limply by the side, are swollen; let the arm be lifted in its flaccid state, while the veins are watched, and, in normal resting people, these will flatten as the hand comes to the height of the manubrium. The arm must be lifted passively; it must not lift itself, for active movement brings the muscles of the limb into play, and these press upon the veins and disturb the test. Another and better gauge is to place the subject upon his back, the head resting upon pillows (Fig. 2). The sternal jugular veins are then usually to be seen as swollen vessels in the neck, but, as they are traced upwards, the swelling ends; it ends at a point that represents atmospheric pressure in the veins, and in normal people this is at a point of the neck that is level with the sternum, or a little higher or a little lower.

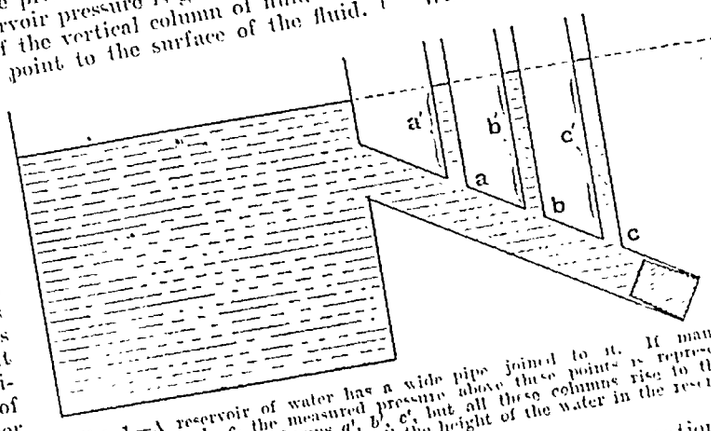

FIG. 1.—A reservoir of water has a wide pipe joined to it. If manometers are attached at *a*, *b*, *c*, the measured pressure above these points is represented by the increasing size of the columns *a'*, *b'*, *c'*, but all these columns rise to the same zero level (Z.L.). All indicate equally well the height of the water in the reservoir.

It is necessary to be sure that the swelling ends where it seems to in the external jugular, and that the vein is not merely running deeper in the higher part of its course. To find out, press a finger lightly on the vein below and it will at once fill in its length and show its whole superficial course. The natural swelling of the neck veins will extend perhaps a third of the way to the jaw, more or less, according to the inclination of the neck to the body. Lift the foot of the couch and in the neck the blood tide advances; lift the head of the couch and it recedes. In these acts think of the surface of the venous pool as you would think of the level of fluid in a long pan of water, lifted at one end or at the other; watch the rise and fall so that you may recognize the surface and know its general level (Fig. 3).

The venous zero level rises to various heights in congestion. Where pressure is raised a little the column is seen to [illegible] in the neck of the supine subject as high as the [illegible] of the sterno-mastoid muscle or beyond this [illegible] unmistakably above the sternal level on both sides of the neck. Where pressure is greater, the veins are swollen to the jaw. Note especially that it is not the anatomical point reached in the neck that matters, but the vertical distance above the sternum. The former is affected by the inclination of the neck to the body, etc.

Where pressure is higher still, the veins remain swollen throughout the neck when th head and shoulde are lifted off t bed. The gauge remains unaltered; it is the vertical height to which the swollen veins extend, or may be raised above the sternum without collapsing. The veins are never full in the neck in a normal unclothed person standing easily in ordinary circumstances in the erect posture; in conspicuous congestion they run the length of the neck like cords.

Thorough familiarity with these phenomena and with the very simple hydrostatic principle involved is an essential matter. It is to be observed that the venous system with its many tributaries is treated as a system of simple and open tubes. The tests should be carried out deliberately, with due precautions; more especially is it to be ensured that no article of clothing or tense muscle can press upon the veins between the point of observation and the heart. The subject must be stripped, and the parts concerned must be rendered flaccid, and must be so placed that their position i favourable to venous emptying Sometimes the veins of the ne are at first tense, presumab because their passage through t deep fascia of the neck la freedom; a little passive movem of the head will then open up the way and truer estimates will be obtained. Veins swollen on one side only point to local obstruction of their immediate outlet and have no value from our present standpoint; often such swelling can be released by a little rotation of the neck; the vein that has the lowest pressure is alone to be used as an index of general venous pressure.

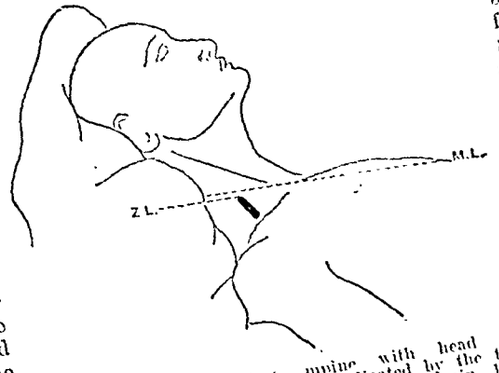

FIG. 2.—Normal subject supine with head on pillows. The zero level (Z.L.), indicated by the top point of swelling of the external jugular vein, lies a little below the manubrial line (M.L.).

A rise of venous zero level in the neck so gauged may be confirmed by gentle palpation of the visible veins, to estimate the tension within them.

The gauges of venous zero level, somewhat less accurate perhaps than manometric readings, are quite exact enough for clinical work, and should be used in part or in whole as a routine in cases of real or suspected disease of the cardio-vascular system. The tests in the neck are preferred to those in the hand or arm, for several reasons. Thus there is less likelihood both of obstruction to, and of muscular emptying of, a cervical vein than there is of a limb vein, since the course is shorter and muscular flaccidity is more readily ensured along this course. Another and important reason is that sclerosis of the veins of the arm is not infrequent; and sclerosis must not be overlooked, as it interferes seriously with collapse; it is readily identified by feeling the emptied vessel. In the legs, the veins, by middle life, and especially the more visible ones over the ankles, are usually sclerosed. In most cases venous pressure in the leg is most difficult to ascertain clinically. In general it may be said that the tests are the more reliable the nearer the vein is to the heart.

I have dealt so far with estimates of the venous zero level by the method of visible collapse. This is the usual method, but there are instances in which no suitable vein in the neck is visible, and here another method is adopted.

The Venous Pulse as an Index.

Not infrequently the position of the venous pulse forms the most reliable sign of normal or raised pressure. A venous pulse at the root of the neck is a normal phenomenon in the supine subject; it is not pathological even if free. In young people this venous pulse commonly shows a great excursion, and is often, though erroneously, regarded as abnormal or is confused with arterial pulsation. To be able to distinguish between the two with certainty is important; it is not difficult, yet there are few who have learnt the ways. In many subjects venous pulsation is obvious at a glance, because it involves superficial veins such as the external jugular, and is evidently within them; in others, and especially those in whom no superficial veins are visible, discrimination is required. Venous pulsation, in the supine and where there is no congestion, involves usually the lower part of the neck along the line of the carotid sheath and subclavian vessels; it is occurring in the internal jugular and subclavian veins, and therefore has a main distribution not dissimilar to that of the chief arteries, but, owing to large tributaries in the subclavian triangle, it is here more diffuse and superficial than is pulsation of the arteries.

The commonest large pulsation in the neck comes from the internal jugular. It frequently extends to and moves the lobe of the ear, and is then usually mistaken for carotid pulsation, a serious mistake to make. Venous pulsation is rarely or barely palpable, while a visible arterial pulse is always felt; the testing finger should be laid as lightly as possible on the pulsating skin, lest by deep pressure the beating of an underlying artery is made perceptible. Venous pulsation is a complex and fluctuating, or a slow and welling movement; it does not jerk sharply to a sustained thrust as does an artery. Such in general are the signs of venous pulsation in the uncongested. In the congested they are modified; more especially the field of venous pulsation is displaced. That is so because *the maximal venous pulsation occurs in veins on the point of collapse*; it is imperceptible in collapsed veins or in veins tightly distended. Thus, in the normal supine subject, the venous pulse occurs in the lowest veins of the neck, for these are just full; it is unseen or lacks prominence in the higher veins of the neck, and that is true of all the cervical veins when the subject is erect. The same change of posture renders carotid pulsation more distinct and brings it particularly into prominence in the carotid triangle, where the artery is most superficial. When much congestion is present and the subject is supine, the veins of the neck are often too tense to pulsate; tip the patient into a more erect, or bring him to a completely erect, posture, and the level of zero venous pressure falls in the neck veins, the tide recedes, and near its margin there appears abundant pulsation. In these patients venous pulsation is often extensive, spreading to the veins of the upper arm and even forearm, and in these parts the association between pulsation and a condition of filling bordering on collapse is often displayed very clearly. Here sometimes, but more frequently in the neck, the level of pulsation is seen to alter with respiration, usually changing to a point nearer the heart in inspiration, because then the venous pressure falls. If this respiratory movement interferes with estimates it can be suspended.

It will be seen from what has been said that the level of maximal venous pulsation approaches closely to the level of zero venous pressure; thus it can be used to confirm the estimate of the point of collapse; it forms the solo gauge when large superficial veins are absent or invisible; in fact, this is the chief bedside value of visible venous pulsation. When veins pulsate freely above the level of the manubrial line they are overfull. Again from this standpoint a thoughtful examination is desirable, for the cervical veins may be overfull, not only because the venous system as a whole is replete with blood, but temporarily because pressure in a part of it is raised by muscular action. Thus, in many normal subjects, if they lean forward as they sit, prominent pulsation appears in the jugular veins; that is so because pressure is exerted in this posture on the abdominal reservoir and blood is displaced to the neck. It can be so displaced artificially in subjects in the supine posture by pressing with the hand on the abdomen; the act tends to flood the neck and to increase pulsation in it. The degree of flooding so occurring is sometimes helpful in estimating the amount of blood held in the abdomen, and in helping to determine the sizes and positions of the cervical veins. Lastly, it is to be said that in congestion the venous pulse tends to lose its fluctuating character, becomes more sustained, and sometimes becomes plainly palpable. In such patients, where the distinction between arterial and venous pulses is sometimes less easy, and depends mainly upon the distribution of the pulse and upon actual visibility or otherwise in superficial veins, the remaining signs of a congested venous system are always manifest.

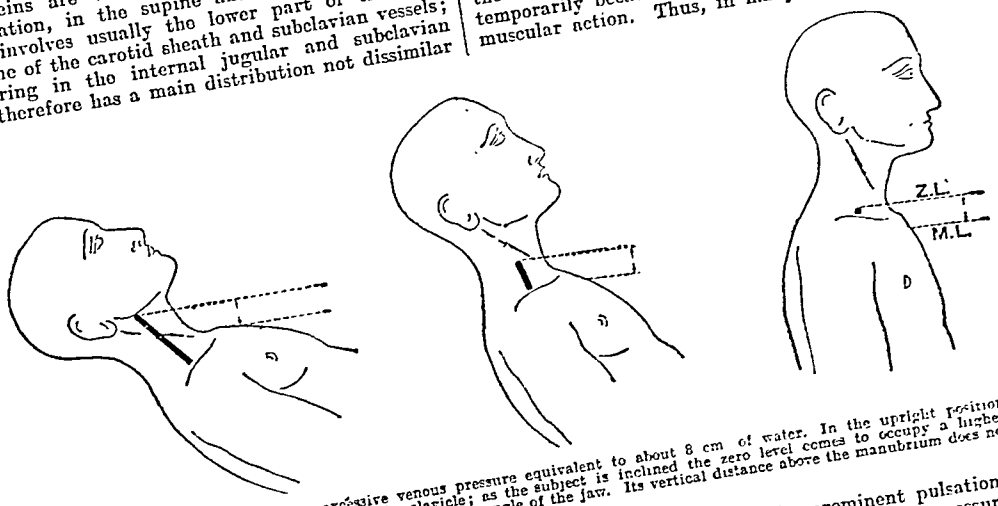

FIG. 3.—A diagram illustrating excessive venous pressure equivalent to about 8 cm. of water. In the upright position the zero level may be just a little above the clavicle; as the subject is inclined the zero level comes to occupy a higher and higher position in the neck until it reaches to the angle of the jaw. Its vertical distance above the manubrium does not change much.

Other Signs of Congestion.

Of the remaining signs associated with venous congestion I propose to say nothing except of those found in the liver, for here also important early signs are found. The firm smooth margin of a congested liver is generally palpable; it is felt at varying levels between the rib margin and the navel, and eventually may be even lower than the last. Failure to palpate the edge of a congested liver is usually the result of beginning to feel the abdomen at too high a level; the whole hand should first be placed, flat and transversely, across the abdomen, well below the navel with gentle yet firm pressure, and gradually worked

upwards until resistance is first felt. If the patient then breathes in and out freely the moving edge of the organ is rarely missed. Percussion is also most helpful; I prefer to use it in the mid-line and of moderate intensity; normally, in these circumstances, the abdomen is resonant to the midriff, for the thin margin of the liver, where it crosses the intercostal angle, fails materially to modify the note, unless the liver edge lies low. Using these methods, early congestion of the liver is generally detectable without difficulty, unless the abdominal wall is unduly thick or tense.

The signs in the veins and in the liver I have emphasized for a chief reason—namely, because they are displayed in early stages of congestion. When the full and classical signs of failure are present, it requires neither close observation nor much discrimination to know it. The diagnosis of early congestion is more difficult, and in the long run it is much more important. It can be accomplished by careful study of the veins and of the liver, and by these means only. Experience teaches that to rely on a single sign is precarious. Compare this sign and that, and confident recognition of the patient's state grows as these signs fall together to form a harmonious picture. Thus, on finding unquestionable evidence of engorged veins in neck, or neck and arms, we look at once at the liver; if we find equally unquestionable evidence that this organ is normal, we know that we are dealing with a local obstruction of the veins. Incidentally, in this connexion observe that veins so obstructed cannot be induced to pulsate. Suppose, however, that in cardiac failure the evidence derived from the veins is indistinct, that there is some doubt whether their pressure exceeds the normal or does not—and this doubt will come to the most or the least experienced observer according to the type of patient under examination—then distinct though slight enlargement of the liver becomes a most important evidence. Generally speaking, enlargement of the liver in its several degrees goes hand-in-hand with engorgement of the veins. In general, the liver does not enlarge before the rise in pressure in the veins can be detected, neither does a distinct venous engorgement manifest itself without the liver edge descending appreciably. There may be cases of difficulty where, owing to fascial obstruction of the upper veins, or enlargement of the liver from causes other than congestion, or failure of the liver to enlarge in congestion owing to cirrhosis, a discord appears. There is also the case in which engorgement of the liver has been present for a very long time; in such, even if the signs of increased pressure in the veins greatly decline, the size of the liver may not decrease much or at least proportionately. But in most instances harmony is found and brings an element of certainty in estimating the degree of failure, and this is so even in regard to early diagnosis. To correlate, and to see accord, in estimating signs is of the utmost consequence, and in this connexion I would emphasize another and most important correlation. *Patients who suffer from general congestion of the venous system are without exception breathless, either at complete rest or upon very slight exertion.* If, therefore, a subject is thought on examination to manifest the early signs of venous stasis, and yet it is clear that breathlessness is not experienced even with quiet or moderate exercise, the opinion first formed must be revised; for it is incorrect. Moreover, there is a perfectly clear relation, constant within narrow limits, between the degree of breathlessness and the pressure in the veins; the relation is so clear that *if it is established that a patient has no congestion of the venous system and is yet breathless in bed, then that breathlessness is not primarily cardiac in origin.* The proper use of this knowledge will save a very large number of serious diagnostic blunders; all that is required is that the point of venous collapse should be proved to occur in any cervical vein at or below the level of the manubrium.

In conclusion, I would repeat that an understanding of cardiac failure of the congestive type is obtainable only by those who truly appreciate the manner in which the symptoms on the one hand and the signs on the other become linked together; the subjective and the objective manifestations are part and parcel of one process, and are dependent on the same fundamental causes, namely, loss of cardiac reserve.

Those who desire efficiently to manage chronic cardiac cases should observe and consider very carefully how little is really gained, and how seldom there is any gain, by repeated auscultation of the heart sounds. Signs so obtained rarely change, they are not signs that indicate improvement or deterioration; but the symptoms and signs upon which emphasis has here been laid do change frequently in one or two directions. They form the chief indications of the course the patient is pursuing and will pursue, for they tell how the blood is circulating in the body generally under various conditions and speak of the capacity of the heart to do work. Those in charge of cardiac patients will do well to acquaint themselves fully with the very definite and sensitive symptoms and the clear signs of early failure here discussed, and to familiarize themselves with the venous manifestations as these occur both in disease and in health.

To understand the phenomena one by one as they are written down and explained is not difficult; to think that such understanding can be brought at once into full play in practical work is to underestimate the situation and to fail in the application; a full grasp and working knowledge can be attained only by diligent observation and thought in which the abnormal is accurately weighed against and considered with the normal.

MYELOMATOSIS, OR BENCE-JONES PROTEINURIA.

BY

A. MACBETH ELLIOT, M.D.

IN November, 1845, Dr. Watson sent a specimen of urine to Bence-Jones, with the question "What is it?" written on a tag of paper. Within a few hours Bence-Jones received a second specimen of urine, this time from Dr. MacIntyre. Both specimens were from the same patient, a man who had been under Watson's care since the previous May. MacIntyre had been called in as consultant.

The man, a well-to-do grocer aged 47, had been ailing for over a year. When first seen by MacIntyre he was thin, emaciated, sallow, pale; his expression was that of suffering, though when not in pain he was cheerful. Pressure along the spine produced little discomfort, but if the pelvis was pressed he complained of severe pain. The arms and legs could be moved freely without any discomfort. Bence-Jones saw the man alive once only, but he received many samples of his urine. The man died on January 2nd, 1846.

In 1847 Bence-Jones read a paper before the Royal Society. After repeated tests and much deep thought, he had arrived at the following conclusions concerning the peculiar deposit in the patient's urine: (1) that the precipitate was an oxide of albumin, and he was satisfied that it was the hydrated deutoxide; (2) that the peculiar characteristic of this hydrated deutoxide was its solubility in boiling water, the precipitate thrown down with nitric acid disappearing on boiling to reappear on cooling. In 1850 MacIntyre published his clinical notes on the case. In the *Dublin Journal* of 1846 Dalrymple had given a full pathological report of the case under the title of "mollities ossium."

I have been unable to trace any further report of a similar nature till the year 1889, when Kahler pointed out the difference between this condition and osteomalacia. Bradshaw, in 1897, described a case, and reported further on it in 1906. Moffat wrote fully on this disease in 1905, and since then there have been various cases reported.

Martin Solon, in his *Traitement d'albuminurie* (Paris, 1838), notes that in one of his cases he came across the peculiar fact that when the patient's urine was treated by nitric acid or heat there was a precipitate which disappeared on boiling; he should therefore be credited with having been the first to draw attention to this peculiar urinary deposit, since apparently it was the same as that found by Watson and MacIntyre.

In October of 1925 a woman was brought up from the country to see me; I was told that it was a case of acute

rheumatoid arthritis of some two years' standing. The following is the history previous to October and subsequently.

The patient was aged 42; both her father and mother were alive and healthy. She had three sisters living, all healthy. She had been married for eighteen years, and had three boys, aged 7, 10, and 15, in perfect health. She had a miscarriage three months after marriage, and another in 1922. As a child she fell and hurt her head, and in 1922 was thrown off her bicycle and injured her knees. She has had no other illness whatever, and was always active in habits. Her periods, which began at 16, were profuse, lasting up to ten days. She was never constipated, and had always been pale.

In 1925, on getting out of bed, her back suddenly "locked," the slightest movement causing agony; she was treated for lumbago for six weeks. As there was no improvement she entered a nursing home, where massage, ionization, radiant heat, and x rays were all tried, with slight benefit for a time. She then returned home, and carried on as well as she could. In 1924 she strained her back when lifting heavy boxes, and the pains became worse.

General Appearance.—Well covered, flabby; intense pallor. While under examination patches of erythema appeared at the root of the neck, spreading up over the left side of the face; also on legs and abdomen. Double dentures. Heart sounds normal, area of dullness increased to right. Blood pressure 160/90. Lungs, a few scattered rales. Liver and spleen not palpable and not enlarged to percussion. No enlarged lymphatic glands found. Abdominal walls flaccid, no glands felt, no tenderness. Knee-jerks slightly increased, especially the left; no tremors, no extensor reflexes; no tenderness of tibiae, and no oedema. All joint movements were free and painless, and there was no evidence of creaking. She complained of pain in the small of her back, radiating to the left shoulder; during the few previous weeks the pain had shot down both thighs. She never had pain in her arms or head. Turning of the body was obviously painful. She first pushed her body up by fixing her elbows, and turned the body slowly, keeping her spine rigid. The tenth, eleventh, and twelfth dorsal vertebrae seemed fixed. There was no tenderness along the spinal column even after strong pressure; no tenderness along the ribs, but a considerable degree along the iliac crests. There was marked hyperaesthesia to gentle stroking with cotton-wool over the right dorsal and lumbar regions, but not to firm pressure.

On first seeing her, three things struck one: her intense pallor, her fixed expression, and her peculiar gait. With joints fixed she advanced by swinging her body first to the right and then to the left, using the hip-joints alternately as pivots. She asked that she should not be assisted in any way, as she had learned how to move with the least pain and discomfort. There was marked pulsation in the left side of the neck. Her expression was one of constant watchfulness, full of such anxiety as is seen in the early stages of tetanus. Her mind was perfectly clear.

A provisional diagnosis of spondylitis deformans was made, and she was advised to enter a nursing home for further examination.

A specimen of urine showed a faint trace of albumin, not clearing up on the addition of acetic acid; there were no casts, blood, or sugar. A few days later Dr. Herbert Lucey sent me the following report on her blood and urine.

Blood.—Haemoglobin 54 per cent.; red cells, 2,500,000 per c.mm.; colour index, 1.08; white cells, 9,375 per c.mm. Differential count: polymorphonuclears 65 per cent., large mononuclears 2 per cent., lymphocytes 31 per cent., eosinophils 2 per cent. No abnormal red cells seen. Wassermann reaction negative. Tubercle complement fixation test negative. Clotted blood showed hydraemia, marked excess of plasma.

Urine.—Clear; albumin present, estimated at 0.6 per 1,000; no sugar. Centrifuged deposit contained no pus, blood, or casts.

Sir Thomas Horder saw her with me, and suggested that it was a case of Bence-Jones albumosis. Dr. Stanley Melville took x-ray films, and wrote: "I wonder if it may not be a condition of myelomatosis, in which case one ought to find Bence-Jones protein in the urine. The only thing against this is that there are not the multiple fractures that are usually associated."

I still inclined to spondylitis, with considerable endocrine disorganization. During the past few months the patient had noted that she was some two inches shorter in stature.

A further letter from Dr. Stanley Melville put spondylitis out of court. He wrote: "The x-ray picture is unlike one of spondylitis deformans, the latter is in the nature of a sclerosis, whereas the present is an osteoporosis with loss of bone tissue. I am still of opinion that the condition is one of disease of the bone marrow."

It was obvious that no improvement was taking place; the pains became worse, and she was less inclined to try any movement. Further examinations on November 5th resulted as follows.

Blood.—Haemoglobin, 0.45 per cent.; red cells, 2,120,000 per c.mm.; colour index, 1.07; white cells, 6,600. No abnormal red cells were present.

Urine.—Protein: heat shows fair cloud; the proteins present are albumin, globulin, and proteose. Bence-Jones reaction is negative. An occasional hyalo-granular cast in the deposit. Range of function as gauged by urea concentration and specific gravity (Calvert's modification of MacLean's urea concentration test): Maximum concentration of urea 2.4 per cent., minimum 1.066. The maximum concentration is fair and the range of function good. The maximum specific gravity 1012, minimum 1006. The maximum cent.; maximum concentration is fair and the range of function good. The kidneys are working efficiently, though there may be some kidney damage, as shown by protein present and occasional casts.

Towards the end of the month her condition grew gradually worse. The bowels became irregular, she had a prolonged and very profuse period, and bronchial catarrh supervened.

On December 4th the blood picture was as follows; haemoglobin 34 per cent.; red blood corpuscles 1,670,000 per c.mm.; colour index 1; white blood corpuscles 6,875 per c.mm. Slight irregularity in size of the red cells was noticed.

On December 22nd a blood count showed: haemoglobin 34 per cent.; red cells 1,330,000 per c.mm.; colour index 1.1; white blood corpuscles 10,000 per c.mm. Marked anisocytosis was present.

Examination of the urine on the same day resulted as follows: Total protein greatly increased, including albumin, globulin, and proteose. No evidence of Bence-Jones reaction. Numerous granular casts and leucocytes present.

In January she developed a broncho-pneumonia, which ran for over three weeks, leaving her with a harassing cough, but even this disappeared towards the end of the month. Early in February the kidneys ceased to function, the urine became scanty, and she died.

Many examinations of the urine had been made during the previous months; occasionally there was a Bence-Jones reaction. During her November, December, and January periods she had very severe menorrhagia.

Dr. Lucey's further report on the urine is as follows:

"A coagulum certainly appeared at a low temperature (55° C.), but did not apparently dissolve on further heating. When the urine was diluted twenty times it did not form a ring with strong hydrochloric acid, which Bence-Jones proteose is said to do—a reaction known as Bradshaw's. The following procedure was then carried out: The urine was heated in the water-bath at 58° C. for half an hour, and a dense coagulum ('A') formed at this temperature, and was allowed to settle. The supernatant fluid was then pipetted off and filtered. The clear filtrate was again heated at 72° C. A second dense coagulum ('B') due to albumin appeared. The temperature was raised to boiling point, and this coagulum was removed by filtration. Some of the first coagulum ('A'), was then added to the final filtrate and heated. It dissolved, but did not reappear on cooling. You will see that the urine did not give a complete Bence-Jones reaction. I have little doubt, though, that this peculiar proteose was present as the coagulum that appeared at 58° C., and that the tests for it were affected by the salt content and albumin present."

Permission was given to hold a partial necropsy. This was done by Drs. H. J. B. Fry and Herbert Lucey.

Dr. Lucey's Report.

"With the exception of a thin eggshell covering of bone, through which the finger could be easily pushed, the bony structure of the bodies of the lower dorsal and all the lumbar vertebrae was replaced by a soft dark red growth, which reached down to but did not infiltrate the dura mater. The intervertebral discs were intact. The growth also involved both ilia, which were much thinned and very fragile, and secondary deposits were found in the sternum and some of the viscera. Microscopical examination of the growth showed that it consisted almost entirely of plasma cells, with practically no stroma. Here and there a larger type of cell, probably the megalokaryocyte, could be seen, but there were no multinucleated giant cells such as are found in a myeloma of a limb bone. The condition was one of myelomatosis. The kidneys showed marked degenerative changes of their tubular epithelium."

Dr. Fry's Report.

"The necropsy showed a marked myelomatosis affecting the sternum, the spinal column, and the pelvis. As far as one could tell the long bones were not affected. The spine from the lower thoracic region to the sacrum showed a sort of fenestrated condition of the bodies of the vertebrae, so extensive was the infiltration. The iliac bones also showed widespread deposits. There was a tiny hypernephroma in the cortex of the left kidney. Apart from wasting, the abdominal viscera were quite healthy, and no growths were present. The lungs and heart were also free from disease. Histologically the growth was a myeloma of the plasma cell type. The hypernephroma of the left kidney was an isolated condition, and not related to the general disease. The Bence-Jones albumosuria which was found by Dr. Lucey was a part of the general myelomatosis."

Here is the case of a woman apparently in perfect health. On rising one morning she is gripped by a sudden intense

pain across the back. Lumbago was the obvious diagnosis; but after six weeks, though easier, the pain was still there, and no line of treatment gave any permanent relief. The weeks became months, and the first year passed into the second. The final months may have been interesting—clinically; they were painful to watch, and emphasized our hopelessness to help. A noteworthy feature was that never once did she realize that she would not recover; she was continually making preparations for going home.

An *x*-ray film taken within four months of the onset gave no evidence of any bone alteration; true, it was not a very good film. There was no fracture of any of her bones; but in this disease the long bones are not usually invaded. She had marked uterine fibroids, which accounted for the severe menorrhagia throughout life. But this cannot be taken as a predisposing cause. What was the cause of the initial lumbar pain? Was it a coincidence—a true attack of lumbago?

In comparing the notes of this case with those taken by MacIntyre in 1845-46 the similarity of the symptoms between the two is very marked. Sex is the chief difference. Myelomatosis is said to occur more frequently in men than in women.

Bence-Jones protein is found in other conditions, but only in a few; its appearance in any urine will naturally call attention to one of them. The fact that it precipitates at between 40° and 58° C., and disappears on boiling, may escape general observation unless a careful watch is kept for it. Many urines with this unusual peculiarity may have been examined and nothing particular noted. The source of this peculiar protein is still a matter of conjecture. Ottenberg, Gies, and Rosenbloom maintain that it is an osseo-albumoid.

THE TUBERCULIN TREATMENT OF ASTHMA.

BY

JAMES MAXWELL, M.D., M.R.C.P.,

ASSISTANT PHYSICIAN, ROYAL CHEST HOSPITAL, LONDON; CHIEF ASSISTANT TO A MEDICAL UNIT, ST. BARTHOLOMEW'S HOSPITAL.

THE multiplicity of methods advocated by various authorities for the treatment of asthma is an eloquent testimony to the complexity of the problem. A method which may give complete success in some cases may be quite valueless in many others not obviously different in any essential particular, and hence it is impossible to write of a "cure" which shall be applicable with certainty even to a majority of sufferers from this complaint.

We are therefore reduced to the employment of many different methods, empirically selected, and of which in most instances the mode of action is imperfectly, if at all, understood. Of these methods, one in particular, the subcutaneous injection of increasing doses of old tuberculin, has been under critical trial in the out-patient department of the Royal Chest Hospital for a period of two years, with results which appear to be worthy of record.

The method was introduced by Professor Storm van Leeuwen as a result of his observation that a considerable number of asthmatic patients were sensitive to tuberculin as shown by the cutaneous test. There was no suggestion that the asthmatic state was the result of sensitization to the protein of the tubercle bacillus, and the beneficial results of tuberculin therapy were ascribed to a non-specific desensitization. In a paper published over a year ago, T. M. Ling[1] reported good results following upon the use of this method in a series of twenty-four children. The initial dose was 0.1 c.cm. of a 1 in 1,000,000 dilution, but the maximum dose was not stated. The results showed two "cures" and fifteen cases improved, and Ling was of opinion that the method was of definite value in the treatment of asthma.

A series of nine cases was also reported by Simpson and Stone[2] a year ago. They found that in four of these cases the patients derived considerable benefit from this method of treatment, and they outlined a simple scheme of dosage. It is noteworthy also that in none of their cases did they obtain a positive skin reaction, a finding which makes the rationale of the treatment a little difficult to understand.

The cases about to be described in the present series presented themselves for treatment at the Royal Chest Hospital during 1928. Thus all have been under observation for more than one year, and several for nearly double this period.

Difficulty was at first experienced in the selection of cases, for it is notorious that some forms of asthma will derive benefit from almost any form of treatment, whereas others appear to need one particular method to bring about a similar result. The obvious explanation of this discrepancy is that many widely different factors can produce asthmatic attacks in a suitably disposed individual, and that not all cases prove responsive to the same exciting stimulus.

In many cases there would appear to be some exciting factor in the home or place of occupation. It is necessary, therefore, in order to gauge the effect of one particular line of treatment, that the patient's routine life should not be disturbed. In other cases a predominant part is played by a septic focus, situated usually in the throat or nasopharynx. It is obviously an elementary principle that such foci should be eradicated in all cases if a permanently successful result is to be obtained, and this procedure was adopted as a routine. Only such cases as did not derive appreciable benefit from this treatment were considered suitable for tuberculin. In addition, routine protein sensitivity tests were performed, with, on the whole, disappointing results; a few positive reactions were obtained, chiefly to the epidermal group, and attempts were made when possible to relieve the condition by avoiding contact with the offending substance, with, as a rule, but scant success. In these cases, also, the failures were passed on and regarded as suitable for tuberculin. No attempt was made at specific desensitization.

The patients were therefore carefully selected, and consisted only of the more severe cases in which routine methods had failed, or were unlikely to afford relief. The total number accepted for tuberculin treatment during the year was thirty-six, and it is the object of this communication to describe the results of treatment in these cases. Of these thirty-six patients, twenty were males and sixteen females; the ages varied from 5 to 49 years, and twenty-one were under 14 years of age when treatment commenced.

A preliminary intradermal test was performed in every instance, after making every effort to exclude the presence of a tuberculous lesion anywhere in the body. The routine test consists in the intradermal injection of 0.1 c.cm. of a 1 in 1,000 dilution of old tuberculin, freshly prepared, in normal saline. The reaction is at its maximum in forty-eight hours, but readings had to be taken on the subsequent out-patient afternoon, so that the interval which actually elapsed in this particular series of cases before the results were read was three days. It was considered that the delay in reading the results made only a negligible difference to the recorded size of the reactions, and they were accordingly noted in the usual manner. The essential feature of a positive intradermal tuberculin test is an area of swelling, erythema being of little significance. The results were as follows:

Negative reactions	24
Positive reactions	8
Strongly positive reactions	4
Total	36

There was a considerable preponderance of negative reactions, a result not in accord with the original observations of van Leeuwen, but nevertheless corresponding closely with the result obtained by me in a separate series of 103 apparently non-tuberculous subjects, of whom 74 were found to yield negative and 29 positive reactions. The objects of this routine preliminary test were, first, to investigate the basis on which the test was originally founded, and, secondly, to furnish an indication as to the appropriate strength of the initial subcutaneous dose. As was to be expected, modifications in technique had to be

introduced from time to time, and the method about to be described is that which appeared to be suitable for the majority of patients, although it cannot be said that a routine standard method was employed in every case.

The material for injection consists of decimal dilutions of old tuberculin contained in rubber-capped bottles, the dilutions ranging from 1 in 1,000,000 to 1 in 100. The size of the initial dose depends upon the result of the intradermal test. With very marked reactions it is advisable to commence with 0.1 c.cm. of the 1 in 1,000,000 dilution; with weaker reactions, a similar quantity of either 1 in 100,000 or 1 in 10,000 dilution, according to the degree of swelling in response to the intradermal test; while with negative reactions it is quite safe to commence with 0.1 c.cm. of the 1 in 1,000 dilution. In all cases the injections are given weekly at first, and the doses are cautiously increased, care being taken to avoid even local reactions, as it is stated that an overdose may precipitate an attack of asthma. The usual method of increase when the weaker dilution—from 1 in 10,000 to 1 in 1,000,000—are being employed, is to follow the initial 0.1 c.cm. with 0.2, 0.4, and 0.6 c.cm., proceeding thence to 0.1 c.cm. of the dilution immediately stronger. This course is followed until the 1 in 1,000 dilution is reached, and at this stage there are usually obvious signs of improvement in favourable cases. The interval between the injections is now increased to two weeks, and the dose is increased by 0.1 c.cm. at each attendance until a maximum of 0.5 c.cm. is attained. This dose may be repeated at monthly intervals as often as necessary. It will be seen that the exact length of the course must vary with the strength of the original injection, but it must also be understood that the exact details are susceptible of considerable modification to meet individual requirements.

When the selected initial dose is 0.1 c.cm. of 1 in 1,000 dilution—that is, in those patients who are not sensitive to tuberculin—the same dose is injected weekly for six weeks, and is then increased by increments of 0.1 c.cm. to 0.5 c.cm., this dose being repeated fortnightly as long as may be necessary.

It sometimes happens that patients lose their symptoms readily under this treatment long before the highest stated dose is reached. In such cases it is not necessary to increase the dose to this extent, but the maximum dose should not be less than 0.1 c.cm. of the 1 in 1,000 dilution. On the other hand, some patients, while showing definite improvement, do not completely lose their symptoms when receiving 0.5 c.cm. of the 1 in 1,000 dilution. In these cases the dose may be cautiously increased with benefit. The maximum dose which has been given in this series is 0.4 c.cm. of the 1 in 100 dilution. This course should only be followed in cases where it is clearly indicated, as no benefit is gained, and the patients are actually not so well, when the optimum dose is exceeded. It is essential that the course of treatment should be prolonged, the minimum satisfactory period being six months.

The results of this form of treatment in the series of thirty-six cases can be classified as follows:—

(*a*) *Satisfactory Result.*—A period of between one and two years is much too short to enable the term "cure" to be applied. The cases included in this group have been strictly observed, and, after the first few injections, have been completely free from attacks and without any symptoms of respiratory embarrassment. The group, therefore, consists of those cases which have obtained the maximum possible benefit. Of the original thirty-six cases, no fewer than seventeen are classed in this group, all being still under observation, and this result agrees closely with van Leeuwen's observation that 50 per cent. of his cases were cured by this method.

(*b*) *Improvement.*—This group includes all cases in which there was a definite diminution in the number of asthmatic attacks, yet without complete relief of symptoms. In many of the cases the record was spoilt by only one or two attacks in the course of the year, and it must be remembered that all of the cases selected for treatment had previously suffered severely from the disease. Twelve cases are included in this group, making a total of twenty-nine patients who derived benefit from this course of treatment.

(*c*) *Failure.*—The criteria which determine inclusion here are obvious, and the remaining seven cases come under this heading. No patient was made worse by the treatment, their last state being as their first.

A glance at the accompanying table will make clear the relationship between tuberculin sensitiveness and the result obtained.

	Result.		
	Satisfactory.	Improved.	Failed.
Intradermal test:			
Positive	4	4	4
Negative...	13	8	3
Totals	17	12	7

It can be seen that, although the figures in each group are small, the proportion of successes is actually greater in the non-sensitive group, whereas in the cases which were sensitive to tuberculin the results are evenly spread throughout the three groups. From this it may be safely argued that sensitiveness to tuberculin plays no part in the production of the result, and that, in fact, the success of the treatment depends upon a non-specific desensitization.

In passing, it may be mentioned that the age of the patient made no difference to the result, although it was noted that in adults the relief of symptoms was sometimes delayed.

Conclusions.

Tuberculin treatment is of value in a considerable number of cases of asthma which prove resistant to other therapeutic methods. It can be used in spasmodic asthma in patients of any age, and in careful hands is without harmful effect upon the patient. To ensure success it is essential that the course should be prolonged, and, if necessary, it may be repeated. The results recorded compare very favourably with those of other and more complicated methods of treatment, and appear to justify its more general adoption, particularly in cases which do not yield readily to simple routine measures.

MUSCLE EXTRACT IN THE TREATMENT OF ANGINA PECTORIS AND INTERMITTENT CLAUDICATION.

BY

M. S. SCHWARTZMAN, M.B.

SUCCESSFUL results in the treatment by muscle extract of angina pectoris, particularly of the variety known as "angine d'effort" (Vaquez) or angina ambulatoria (Wenckebach) were reported some time ago by Professor J. S. Schwartzman of Odessa.[1] These results have since been confirmed in Russia and Germany. Among other observers, Fahrenkamp and Schneider of Stuttgart published gratifying results relating to the treatment of some hundred hospital heart cases with anginal syndrome. I have been trying this treatment for a few months now with very promising results, which I hope to be able to publish in full in due course. The underlying considerations on which the method of treatment of angina pectoris by means of muscle extract is based are as follows.

A peculiar phenomenon was described by Professor Schwartzman in 1927,[2] occurring invariably with a hypotonic heart muscle, as in infectious diseases, anaemia, cachexia, chronic pulmonary tuberculosis, starvation, heart failure, etc. If the patient is made to contract any muscle group, one notices muffling of heart sounds, shortening of the systole, diminution of intensity or even disappearance of systolic murmurs, if any; all this being the result of diminution of the amplitude of the cardiac contraction. The inhalation of amyl nitrite, injection of adrenaline, and the immersion of hands in hot water tended to abolish this phenomenon. This heart reflex was thought to bear a certain resemblance to what happens in an attack of angina pectoris, in which the coronary angiospasm might be accompanied by a muscular spasm.

It has been further observed that a few preliminary muscular exercises would likewise abolish the phenomenon. The fact is known to every cardiologist that anginal pain sometimes disappears as the patient continues his effort. One such patient, who at necropsy was found to have extensive sclerosis of the coronary arteries, was accustomed to exercise vigorously "to work off the pain" when the attack began.[4] Heberden described the most striking case of this type. Hence arises the assumption that some sort of antispastic substance is at work during the contraction of active skeletal muscle. Such substances obtained from skeletal muscle of a healthy young animal might counterbalance the spasm in angina pectoris. Their deficiency in the muscular system, on the other hand, would be an important factor in production of the anginal syndrome.

Reid (quoted from *Recent Advances in Cardiology*, by Terence East and Curtis Bain, p. 20) seems to approach this idea when he states that angina pectoris occurs when there is a failure of a depressor mechanism, which in moments of strain should lighten the load of the heart. He suggests that there are peripheral changes, which lower pressure by inhibiting the vaso-constrictor tone, so that in moments of stress in healthy individuals there is actual vaso-dilatation. In angina pectoris these mechanisms fail, and the strain on the aorta becomes too great. Such depressor mechanisms might be put into action by means of the above-mentioned antispastic substances. Since I intend to publish soon a detailed account of results obtained by me with muscle extracts in angina pectoris, I shall confine myself at the moment to the following illustrative case.

A man, aged 58, with no children and no history of venereal disease, had been suffering for six years from pain starting from the substernal region and spreading upwards towards both arms. This pain appeared on walking, and compelled the patient to stop for a couple of minutes, after which he could continue for another period. He could walk without pain for about 100 to 200 yards. Under the most favourable circumstances, including good weather, he could only walk half a mile.

On examination it was found that the heart was slightly enlarged to the left. The second aortic sound was accentuated, and the blood pressure was 170/100. The pulse was 84, and the radial artery was tortuous. On screening, the heart was shown to be enlarged, and the aorta considerably so. An electro-cardiogram (June, 1926) recorded obvious inversion of the T wave in leads 2 and 3, but the blood had a negative Wassermann reaction and the lungs were normal.

Treatment by daily injections of a muscle extract* was started on January 27th, 1930, and continued until February 17th. After the third injection improvement of sleep was noticed, and after the sixth injection the sensation of constriction around the chest became diminished. By the time that the twelfth injection had been given the patient was able to walk two and a half miles with no sensation of pain. The general condition is now much improved and he is definitely stronger, there being no discomfort on exertion, except immediately after meals. Treatment was stopped for ten days, but the improvement was maintained; it was restarted on February 27th, and is being continued twice a week. The walking ability is still two and a half miles at the patient's normal pace.

In view of the striking resemblance of angina pectoris to intermittent claudication (which is rightly termed by some angina cruris) I have felt justified in treating cases of intermittent claudication by the administration of muscle extract—a method not hitherto attempted, so far as I know. Whatever the pathological variety of this condition may be—(1) angiospastic or vasomotor (Oppenheim); (2) arterio-sclerotic (Charcot, Erb); or (3) thrombo-angiitis obliterans (Buerger)—it is the vaso-spastic factor in all three varieties which I thought might be influenced by the extract. This research is still in progress, but the encouraging results obtained so far seem to me to justify this publication.

The following are some of the cases under treatment.

CASE I.

An unmarried solicitor's clerk, aged 40, with no history of venereal disease or alcoholism, but smoking twenty cigarettes a day, complained of severe crampy pains in both legs on walking, chiefly in the thighs; these were first noticed in April, 1929. After walking a distance of forty yards the onset of the pain compelled him to stop, but when he had rested for a minute or two the pain disappeared and he could continue walking. Restriction of smoking, rest, and medicinal treatment failed to alleviate the pain. As the result of reducing treatment he lost 2 st. in weight, but the condition was unchanged. He was admitted to Westminster Hospital under Sir James Purves-Stewart on January 28th, 1930.

On examination no abnormality was discovered in the digestive or cardio-respiratory systems. The blood pressure was 165/90. The knee-jerks were brisk, and the plantar reflexes flexor in type. The posterior tibial arteries were faintly felt on both sides, but neither dorsalis pedis artery was palpable. Movement of the right leg against resistance caused blanching of the big toe. The urine was normal and the Wassermann reaction negative. Radiographic examination of both legs revealed no arterial calcification.

Injection of muscle extract was started on January 30th, and while at the Westminster Hospital the patient had eleven injections. After the fifth he was able to walk a distance of 120 yards; with subsequent injections this was increased up to half a mile. He is now able to walk without pain; at the end of half a mile there is slight leg weariness, but no pain. His legs feel firmer, his general condition is improved, and he has resumed work. The pulse is now easily palpable in the dorsalis pedis arteries, and the blood pressure has fallen to 130/90. There is no blanching of the big toe on exercise against resistance. Treatment is still being continued three times a week.

CASE II.

A widower, aged 63, with no history of alcoholism or venereal disease, and a moderate pipe-smoker, complained of pain for about nine months and leg weariness on walking. The pain was localized to the calf muscles, and he was compelled to slow down or even to stop entirely. The distance which he could walk without pain ranged from 200 to 500 yards.

On examination the eyes and cranial nerves were found to be normal, the reflexes brisk, there was no clonus, and the plantar reflexes were flexor in type. Superficial and deep sensations were normal. The skin on the legs was bluish in colour, and the feet were rather cold. The pulse in the posterior tibial and dorsalis pedis arteries was palpable. *X*-ray examination revealed extensive calcification of the arteries down to the ankles. The heart was enlarged, half an inch outside the mid-clavicular line, and the second aortic sound was ringing. On screening the aortic arch was seen to present a bulging dense shadow, and the descending aorta was distinctly visible in the second oblique position. The radial artery was tortuous, and the blood pressure was 170/90. The liver was not palpable, the urine was normal, and the Wassermann reaction negative. The appetite was normal, and the bowels acted regularly.

After eight injections of muscle extract the patient noticed that the leg weariness and pain had decreased, and the legs felt stronger. After the twelfth injection the pain and tiredness had ceased. The treatment is still being continued at longer intervals.

CASE III.

A married manual worker, aged 52, with five children; there was no history of alcoholism or venereal disease; he was a moderate smoker—ten to twelve cigarettes a day; he complained of pain in the muscles of the calf, which "got hardened on walking." He had to stop for a time after proceeding for about 100 yards, and then could continue again for about the same distance. He had a sensation of cold in both legs. This condition had lasted for two years.

On examination the pupils and jerks were normal, and there was no evidence of any lesion in the nervous system; the toes, particularly on the right foot, had a bluish tint, and the pulse in the posterior tibial and dorsalis pedis arteries was not felt. Radiograms showed no calcification of the vessels, but the heart was slightly enlarged to the left; screening revealed enlargement of the aorta, both ascending and descending portions being seen to pulsate. The blood pressure was 150/80, and the Wassermann reaction was negative. The administration of iodides and bromides for more than a year had no effect.

Injection of muscle extract was started in February, but no change was registered until the eleventh injection, after which the patient began to walk better, feeling less pain and tiredness. After the sixteenth injection with an increased dose he could walk 300 yards. He was admitted to the London Jewish Hospital, and after ten more injections could walk 900 yards without inconvenience; at the end of this distance he feels pain in one leg only; he is still under treatment.

In conclusion, I wish to express my gratitude to Sir James Purves-Stewart for his interest and encouragement in this work, and for permission to carry out the treatment on his patient at the Westminster Hospital. I wish also to acknowledge my indebtedness to Dr. G. Konstam, assistant physician to the London Jewish Hospital, for permission to treat one of his patients.

*The work is still in its experimental stage in so far as the dose, concentration, and method of preparation of the muscle extract are concerned, and the preparation has not appeared on the market yet; it is hoped that it will be obtainable in a short time.

TREATMENT OF TUBERCULOUS KNEES BY THE CAUTERY.

BY

A. Z. C. CRESSY, M.R.C.S., L.S.A.,

HONORARY SURGEON, CARSHALTON AND DISTRICT MEMORIAL HOSPITAL.

TUBERCULOUS knee-joints are not seen so frequently as they were thirty years ago; this is no doubt due to the advance of science and to better housing, sanitation, open spaces in crowded cities, better choice of food, and plenty of fresh air and sunlight. But still the disease does exist, and will do so for many years to come.

In the early days tuberculous joints were blistered, strapped with mercurial ointment, and partly rested, with very indifferent results. In these later days such joints are mostly kept at rest, extension being applied for long periods; many excellent results follow, but the treatment has to be continued for a very long period. It is to expedite the cure of these cases that I venture to advocate the cautery, which is occasionally mentioned in textbooks, though I have never seen its application described.

One of the greatest advocates of this mode of treatment was Professor Syme of Edinburgh. In his observations on clinical surgery, which were published in 1851, he mentioned the extraordinary and apparently almost magical effect which is produced in certain forms of articular disease by the actual cautery; this form of treatment had been introduced into Great Britain little more than thirty years previously for the purpose of counter-irritation, and is one of the most valuable curative means employed in the practice of surgery. Syme took every opportunity of emphasizing the advantage derived from its employment, but for many years his efforts produced little effect, and the proposal was often scouted as no less shocking to humanity than degrading to the profession. He describes a case of strumous knee, and adds that in such cases the actual cautery, if properly applied before suppuration has taken place, may be regarded as very nearly, if not absolutely, a certain remedy. We have, however, no description of his method of applying it, and he was operating before the days of aseptic or even antiseptic surgery.

I have been using the actual cautery for the cure of tuberculous knees for a period starting in 1890; my list comprises eight patients, both knee-joints being involved in two cases.

The typical case to choose is one in which the synovial membrane is chiefly involved, there being a pulpy thickened swelling, with perhaps some fluid, lateral luxation, limited movement forwards and backwards, and pain; there must be no grating or evidence of bone implication. In other words, the earlier the case is taken in hand the more certain is the chance of permanent cure with perfect movement.

The operation is simple. Three incisions are made with the cautery on either side of the knee from before backwards; one below the level of the knee-cap, one in a line with the middle of the knee-cap, and one above, on each side of the knee. The incisions must not meet in the middle line of the knee either before or behind. The cautery must completely divide the skin and must expose the fat; at this point the incisions gape laterally, and burning of the fat is evidenced by the smell. The application of sterile gauze wrung out in hot sodium carbonate solution (1 drachm to the pint) takes all the pain away, and, covered with wool, is an excellent dressing until all the scabs have peeled off, which takes about ten days.

The wounds are dressed daily until all the scabs have disappeared, when zinc and red precipitate ointment can be applied on alternate days. After ten days the knee is gently bent once a day. A back splint is useful during the first fortnight, after which the joint is allowed to move, resting on a pillow. The wounds heal in about six weeks. It is surprising how soon the swelling subsides and the joint becomes of normal size. The patient is able to walk without support in about twelve weeks; the slight support of a bandage may be utilized, but it is not really necessary. The result is the production of six silk-like scars and a very thin knee, with perfect movement.

I have a series of ten knees dating from 1887 to the present time; in eight a complete cure resulted, but in the other two I had to amputate. The two cases needing amputation were badly chosen for cautery treatment, as it was found that the ends of the bones were seriously affected, which is a contraindication. After amputation both patients did well.

Case 1.—My first patient was a girl, aged about 12 years, who had both knees affected. In 1887 I began to treat her with rest, back splints, strapping with compound mercury ointment, and blisters, with periods of resting from treatment, except for a back splint. In 1890 Mr. Jacobson of Guy's Hospital advised the use of the cautery before proceeding to excision; it was accordingly applied to both knees under chloroform in April, June, and August of that year, and as the symptoms had not sufficiently abated it was employed for the last time in June, 1891. The reason for the repetition of the applications was that the cautery incisions were not taken through the skin, as was done the last time. Then came a long period of healing and absolute rest, with the result that by the end of that year she was walking again, and her improvement continued steadily. Thirteen years afterwards Mr. Jacobson reported as follows:

"I have to-day, May 12th, 1903, seen the patient. The cure after this long interval is sound and complete. There is not a trace of thickening or abnormality about the synovial membranes, the movements of the joints are smooth and complete, and the cautery scars are quite sound, thin, and supple."

Case 2.—This patient was a boy, aged 11 years, who, after being treated in several hospitals, came under my care in 1902; his knee was swollen and pulpy, giving the false impression of fluid in the joint. I applied the cautery, the operation being attended with a great deal of shock, an injection of strychnine being necessary, and for a few minutes a pause in operating; the case was subsequently uneventful; the wounds healed, and the patient left the hospital in a Bavarian splint. He has since passed into the marines, in which he served for several years, and is in perfect health at the present time.

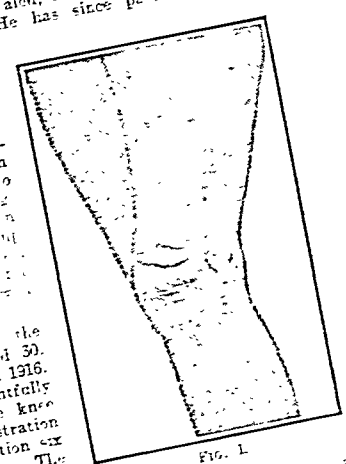

FIG. 1.

Case 3.—A girl, aged 16, who had chronic swelling of one knee with pain and limitation of movement, came under my care in 1906. She was treated for two years with rest and strapping etc. The cautery was then applied, and the patient was up and about exactly six weeks later. She has since played tennis for her county, and is perfectly well to-day.

Case 4.—In this case the patient was a woman aged 30. The cautery was applied in 1916. The wounds healed uneventfully in eight weeks, and the knee became perfect. The illustration (Fig. 1) shows the condition six months after the operation. The rein enlargement is due to pregnancy.

Case 5.—This patient, a woman aged about 22, was seen in 1916. Splints and strapping were tried for some months, then the cautery was applied, and the wounds healed uneventfully with excellent results.

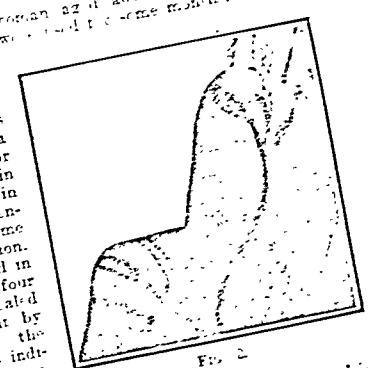

FIG. 2.

Case 6.—The patient was a woman, aged 24, with a history of swollen knees for two years. When seen in July, 1929, she had fluid in both knees, much thickening, lateral luxation, some pain, and limited flexion. One knee was cauterized in July, the other about four weeks later; both healed with perfect movement by November 14th. In the illustration (Fig. 2, is indicated the range of movement, as well as the position of the scars.

These cases, with the two previously quoted which required amputation, make eight patients with ten knees treated. With the later experience of avoiding those cases in which the bone is affected, I think the history of these patients is worth considering, since it indicates a quicker way of curing these very slow and troublesome cases.

THE USE OF STRIPS OF HERNIAL SAC AS FASCIAL (LIVING) SUTURES.

BY

F. R. BROWN, M.B., F.R.C.S.ED.,

SURGEON, ROYAL VICTORIA HOSPITAL, DUNDEE; ASSISTANT SURGEON, ROYAL INFIRMARY, DUNDEE.

SOME years ago (1925), while operating for old-standing oblique inguinal hernia in a man of 57 with weak and lax inguinal musculature, it was my intention to reconstruct the canal by using strips of fascia lata after the method introduced by Gallie and Le Mesurier.[1] Having dissected out and removed the sac, which was unusually long and thick, I was struck by the possibility of using strips cut from the sac itself, in the same manner as strips of fascia lata or of aponeurosis of the external oblique muscle.

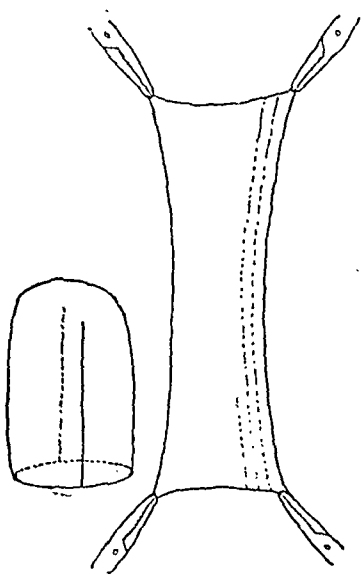

FIG. 1.

In this first case the method adopted was to slit the sac up on either side to within about one inch of the *fundus*, so that the sac when opened out became a rough rectangular sheet measuring about eleven inches by two and a half inches (Fig. 1). From this sheet strips a quarter of an inch wide were cut, and the operation was completed by two rows of sutures, following Gallie's technique.

This case proved completely successful, and I have now used the procedure in a large number, with some modifications in the method of cutting the strips, as illustrated in Figs. 2 and 3. Where a strip the length of the opened-out sac—that is, almost twice the length of the intact sac—would be considered too short, strips may be cut as in

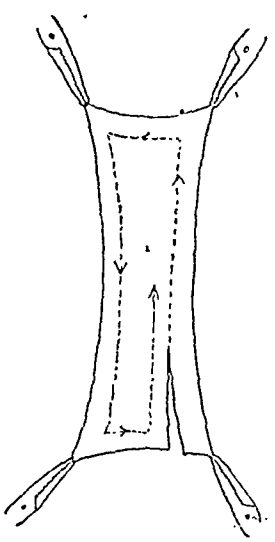

FIG. 2.

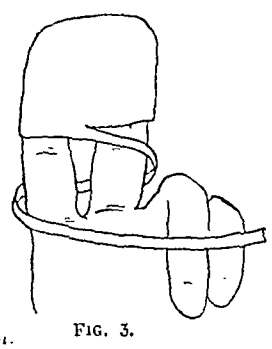

FIG. 3.

Fig. 2, where the whole s[illegible] so far s[illegible] to one or more long ribbons as required. [illegible] sac cut in spiral fashion. In this m[illegible] e of the cases unde[illegible]ied by the assistant's fingers, or may[illegible] retcher or two pairs of long artery [illegible] long strips, suitable for continuous [illegible], but smoking twenty cigarettes a day. moderate size if desired, [illegible]mpy pains in both legs on walking were first noticed in April, 1929. large sac type of hernia th[illegible]ty yards the onset of the pain necessary. The width of the strips ca[illegible] the thickness of the sac; in a la[illegible] may be as much as half an inch sufficiently strong suture.

This procedure may be employed (1) as an alternative to the use of fascia lata or of the aponeurosis of the external oblique, or (2) in conjunction with the latter; in a recent case the sac was so small that, when cut in spiral fashion, only one rather weak strip about twelve inches long resulted, and two supplementary strips of external oblique aponeurosis were used.

So far, I have carried out this method only in cases of oblique inguinal hernia. There are obvious limitations to its use, and rarely would a sac of ample size be present in direct and femoral hernias.

UNDULANT FEVER DUE TO BRUCELLA ABORTUS:

ISOLATION OF THE ORGANISM FROM THE URINE.

BY

COLONEL W. P. MACARTHUR, M.D., F.R.C.P.I., D.P.H., D.T.M. AND H.,

AND

MAJOR J. B. A. WIGMORE, M.B., M.R.C.S., L.R.C.P., D.T.M. AND H., R.A.M.C.

UP to the present seventeen cases of human infection with *Brucella abortus* have been reported in England. In only one of these[1] was the causal organism recovered, in this instance from the blood. The remaining sixteen were diagnosed by agglutination reactions only. It seems appropriate, therefore, to record another case of *Br. abortus* infection, the first in this country in which the organism has been isolated from the urine.

The patient is a lady, aged 53, resident in Manchester. Except for a brief visit to Switzerland ten years ago, she has not left the British Isles during the past twenty years. In April, 1929, she spent ten days holidaying in Ludlow, returning to Manchester on April 22nd. During the second week of May she complained of pain in one ankle, and was feverish and shivery at night, but in the mornings felt better. On the morning of May 13th she was definitely unwell, and her temperature was found to be over 102° F. The febrile attack lasted until May 29th, when the temperature, previously gradually declining, remained normal for twenty-four hours, but on the next day it commenced to rise again. Relapses, of the duration shown, followed the original attack: May 31st to July 16th; July 20th to August 2nd; August 4th to August 7th; September 14th to September 18th; November 2nd to November 27th; December 9th to December 31st. The relapses are counted from the first recorded rise of temperature to the last day that the evening temperature was above normal.

At the beginning of the first relapse the physician in charge, Dr. Florence Robinson, sent specimens of blood, urine, and faeces for examination. Agglutination tests for the typhoid group were negative, and on Professor Shaw Dunn's suggestion the serum was put up against *Br. abortus*, with a positive result. Two blood cultures (June 4th and 10th) were negative. Professor Murray saw the patient in consultation on June 10th, and the case was regarded as probably one of infection by *Br. abortus*, although the causal organism was not isolated.

During the afebrile interval following the fourth relapse the patient came to London, and on November 2nd another relapse commenced. One of us saw her in consultation on November 8th. The general condition was strongly suggestive of undulant fever. She was restless, sleepless, and despondent almost to tearfulness. The temperature fluctuated usually between 101° and 103°, and once reached 104°. Nevertheless there was little prostration, and the efforts of the nurse in charge were necessary to prevent the patient from rising at night and wandering about the house. The pulse rate was from 80 to 90. Tenderness was marked over the splenic area, but there was a difference of opinion as to whether or not the spleen was palpable. The tongue, which had been covered with a silvery fur at the beginning of the relapse, was then clean except for some persisting patches. One ankle was painful and tender. The bowels were loose, and dark offensive motions, free from any trace of mucus or blood, were passed, sometimes as many as six in the day. Obstinate constipation had been a feature of the five previous attacks. On November 10th a red papular rash appeared rather thickly over the body and limbs; rashes of various types are, of course, not uncommon in "Malta" fever. At this stage the tongue had become quite clean, and the appetite was good.

Catheter specimens of urine were taken for culture on November 11th and 12th. The first was sterile. Of the second sample 10 c.cm. were added to each of twelve tubes containing 10 c.cm. of glucose

CASE I.

[illegible]al stage in so far as the [illegible]drips [illegible]ation of the muscle extract [illegible]a appeared on the market yet; it short time.

broth, and incubated for forty-eight hours at 37° C. Two of the tubes showed cloudiness. Subculture of these on agar plates gave a growth of circular, convex, translucent colonies which microscopically showed small Gram-negative organisms distinctly more bacilliform than *Br. melitensis*. They did not ferment any sugar, and gave an alkaline reaction in litmus milk.

This organism was agglutinated by serums prepared from three undoubted strains of *Br. abortus*, with end-points as follows:

1. Swine strain of *Br. abortus* . ... up to 1 in 2,500
2. "*Abortus* No. 5" ... . up to 1 in 1,250
3. "Bang" (Oxford strain) ... .. up to 1 in 500

It is important to note that these serums were prepared by injecting rabbits with living cultures. The standard agglutinating serum of Oxford (prepared from dead cultures) did not cause any agglutination. The organism was not agglutinated by serums prepared from two undoubted strains of *Br. melitensis*, but it is significant that a serum prepared from a strain of *Br. paramelitensis* gave an agglutination up to 1 in 500.

A serum was prepared by injecting a rabbit intravenously with increasing doses of living cultures of the organism under examination. This serum agglutinated thirteen different strains of *Brucella*, the highest end-point (1 in 1,250) being given by the swine strain of *Br. abortus*.

The patient's blood serum agglutinated twenty-two different strains of the *Brucella* group, giving titres up to 1 in 250 with *Br. melitensis* and *Br. paramelitensis* strains, and up to 1 in 2,500 with the swine strain of *Br. abortus*. Using the standard agglutinable cultures of Oxford, and of the Royal Army Medical College, the *Br. abortus* cultures agglutinated up to titre, but the *Br. melitensis* cultures did not agglutinate up to more than half the full titre.

An autogenous vaccine was prepared and its administration commenced after the last relapse. Up to the time of writing (March 28th, 1930) the patient has remained free from any further symptoms of the disease.

The strain of *Br. abortus* isolated from this patient grew readily from the urine in ordinary media, and in the absence of an atmosphere of CO_2. This, together with the result of the agglutination tests given above, suggests that it belongs to the swine variety.

A CASE OF BRUCELLA ABORTUS INFECTION.

BY

E. ROLAND WILLIAMS, M.A., M.R.C.S., L.R.C.P.,

MAENCLOCHOG;

AND

A. F. SLADDEN, M.A., D.M.OXON.,

DIRECTOR, BECK LABORATORY, SWANSEA

UNDULANT fever due to the organism which sets up epizootic abortion in cattle, goats, sheep, and swine has been described as "a disease of the future," and also as a possible addition to the lengthening list of occupational diseases, for it has its highest incidence among those who have direct contact with cattle, live or dead. In 1924 and 1925 ten cases only were recorded in the United States, but in 1928 and the early months of 1929, when physicians had become more widely aware of the disease, over a thousand cases were brought to light during the first year when the disease was systematically sought.

The case about to be described is the second reported to have occurred in Wales and the fifteenth or sixteenth recorded in Great Britain. Possibly, however, the number of cases recorded is not a true measure of the incidence of human infection. It has been suggested also that there is a real extension of the disease in most countries, coincident with more frequent and widespread epizootic of abortion among cattle; in this connexion may be cited cases recently reported from New Zealand by Gilmour and Ludbrook and by L. J. F. Bull.

Wilson and Nutt investigating the mixed milks from herds in Cheshire, Lancashire, Derbyshire, Staffordshire, and Northumberland established the presence of *Br. abortus* in 8.8 per cent. of the samples. Although the mortality is very low (about 2 per cent.) and permanent impairment of health apparently rare, incapacity is often of long duration, many cases being ill for one or even two years. The record of the following case may therefore prove of interest, especially as it exemplifies many salient signs and symptoms of the disease.

On January 6th last one of us was called to see a farmer, aged 53, who had lived all his life in the same locality in Pembrokeshire. He definitely became ill on January 2nd with headache, backache, and nausea, but for a week prior to that he had felt vaguely unwell, getting very fatigued and having to lie down in the afternoons. When first seen he had a temperature of 103°, with a pulse of 95. He had a violent cough, and complained of much headache, restlessness, and insomnia. The heart sounds were rather poorly defined, and the breath sounds were defective at the right base. He was bringing up a type of copious white sputum, which led to the suspicion of some degree of pulmonary oedema. At this time the case was thought to be influenza.

During the days immediately following the temperature remained at 102°, with a relatively slow but feeble and intermittent pulse. The blood pressure (85 125) seemed much below what one would expect in a plethoric man of his age. There was a trace of albumin in the urine. The patient complained of very heavy drenching morning sweats and severe pains in the calves of the legs. There were no definite rigors, and no mention was made of any peculiar odour of the perspiration.

On January 12th the spleen, which was rather soft, could just be palpated below the costal arch. This observation, along with the history of insidious onset, the comparative (though not complete) absence of upper respiratory catarrh, and the fact that no one else in the house had developed influenza, led to a suspicion of paratyphoid, and a blood specimen was sent to the Beck Laboratory. Serum from this, of the tenth definite day of illness, was tested for agglutinative power by the Dreyer technique against *B. typhosus* and paratyphoid A and B, with negative results even in low dilutions.

In view of the companion of the patient and the knowledge that *Br. abortus* infection in man may be acquired from cattle, a further agglutination test with *Br. abortus* (Oxford emulsion) was made, and strong agglutination found up to a dilution of 1 in 2,500. This is well beyond the limit of any non-significant response, and indicated past or present infection by this organism. As cases of "undulant fever" are found to give positive agglutination also with *Br. melitensis*, the organism of Mediterranean fever, the serum was also tested with an emulsion of the latter obtained from Messrs. Burroughs Wellcome and Co.; this test proved positive to a dilution of 1 in 2,500 also.

It is still a moot point whether the two organisms, *Br. abortus* and *Br. melitensis*, are to be regarded as identical or whether they represent two closely allied species. Their clinical effects on the human subject appear to be similar, and both organisms have been shown to produce abortion in the cow. It may be significant that *abortus* cases have been studied chiefly from cow-borne infections, whether direct or through cow's milk, whereas our knowledge of *melitensis* cases comes chiefly from infections arising through goat's milk. It may well be that passage of the organism through the cow and the goat respectively may produce slight serological differences in organisms originally identical.

In the case under consideration there have been no opportunities of isolating the organism, and therefore no agglutinin absorption experiments have been possible. The very definite serological reactions, however, coupled with the very complete clinical picture and the history of the environment and circumstances of the patient, would seem to have established beyond reasonable doubt that this illness was due to infection by *Br. abortus*.

Further inquiries made in the patient's locality brought out evidence that: (*a*) epidemic abortion was especially rife among cattle in the village where the patient lived, (*b*) a cow of the patient's was had "lost their calves" during the preceding six months; (*c*) he last had a cow abort about three weeks before he definitely became ill, into that cow he had inserted pessaries manually in to help to clear her up."

The further clinical course may be summarized thus:

On January 14th the temperature in the evening was down to 100°, with pulse of 84. The cardiac condition had improved and the spleen could only just be felt. Signs were still complicated of there were still had rales at both bases, and pneumonic of the breath sounds were impaired at the right base. On January 15th the chest signs were more pronounced, the temperature was 101°, and the pulse 84. It is was very rare in the [illegible]. On the

night of the 16th he was reported to have been very restless, dyspnoeic, and feverish all night. On January 17th he suddenly coughed up several "gushes of slimy liquid yellow stuff like beaten-up eggs," and it was suspected that a pulmonary abscess or empyema might have formed and ruptured into a bronchus. The patient stated that the dyspnoea eased markedly after this event. When seen at 8 p.m. the temperature was 102°, pulse 84, respirations 30. There was no marked change in the chest signs, and there was still complaint of heavy sweats and pains in the calves.

On January 22nd the temperature was down to 99°. The appetite was good, and the general aspect remarkably good considering the severity of the illness. On the 25th the temperature was 98°, pulse 60, respirations 20; there were still rales at the bases, but no splenic enlargement and no sweats or pains in the legs. Since then there has been no recrudescence of the fever.

This case would appear to have exemplified several outstanding characteristics of the disease as observed in the extensive American outbreaks. The "afternoon fatigability," headaches, and especially backaches, during the stage of onset; the enlarged spleen, the peculiar heavy sweats, the severe pains in the calves of the legs, the relative bradycardia, myocardial involvement, and low blood pressure—all these features figure very prominently in Bierring's detailed description of 150 cases of the disease studied by him in Iowa between 1926 and 1929. In the American descriptions there is no special mention of pulmonary complications, but oedema of the lung is described by Carmichael Low and by Wheeler and Jack as being a frequent event in the closely allied Malta fever.

It is characteristic that only one member of the household was affected. "The disease, though epizootic among cattle, is remarkably discrete among human beings," so that "the typical case is generally the only one in a district, and multiple cases in one house have only once been encountered." (Charles and Warren.)

The mode of transmission is also of interest. Most of the cases previously recorded in Great Britain would appear to have been due to the drinking of infected milk, but here infection would seem to have been due to manual contact with the vagina of the infected cow. The subsequent route of the infection may have been through the unbroken skin of the hand rather than by ingestion of food soiled by the imperfectly cleansed hand; Hardy experimentally infected guinea-pigs more readily through the shaved unabraded skin than through the alimentary tract.

The question of prophylaxis is naturally an important and a thorny one if the disease should really prove to be more common than has been thought hitherto. Most recent writers seem to regard direct contact infection as being much more important than milk-borne infection, and they look to the veterinarian for the first steps towards the eradication of the disease among cattle. In France the disease among cattle is already notifiable. Hardy sums up the prophylactic aspect of the problem thus:

"A conservative attitude is justified since it appears obvious that the disease is not a new one, but one newly recognized. Deaths are very few, serious sequelae are infrequent, and acute suffering is unusual, but there is now occurring an undetermined and probably severe economic loss. In preventing this, the live-stock and dairy industries will apparently be concerned, and a prematurely attempted eradication of contagious abortion would prove both ineffective and disastrous. . . . Much economic waste, and even impairment of human health through decreased consumption of milk, may be avoided by acting wisely and quietly."

We wish to thank Mr. Watson, veterinary surgeon at Haverfordwest, for information regarding the prevalence of epizootic abortion among cattle in the locality concerned.

NOTE ON A FURTHER CASE OF UNDULANT (BR. ABORTUS) FEVER OCCURRING IN SCOTLAND.

BY

W. H. WISHART, B.Sc., AND H. J. GIBSON, M.B., M.B., Ch.B., D.P.H.
(*Bacteriology Department, Edinburgh University.*)

CONSIDERABLE attention has recently been directed towards the possibility of infection of the human subject by *Br. abortus*. The organism is known to be responsible for widespread disease among cattle, while its presence in milk as sold to the public has been repeatedly demonstrated. It may also be noted that the present precautions and requirements in the production of "graded" milks provide no efficient safeguards against the dissemination of this organism, even in milk of the highest class. The question of spread of the disease from animals to man is thus one of considerable importance in relation to public health.

In view of this it may be of interest to record the history and bacteriological findings of a case which recently occurred in the private practice of one of us (W. H. W.). The diagnosis rests on the evidence provided by the serological reactions of the patient's serum, but, as in the case in Glasgow described by Cruickshank and Cruickshank,[1] the presumption is very strong that *Br. abortus* was the causative organism.

History and Clinical Course.

A technical chemist, aged 34, residing in Edinburgh, was seen on January 7th, 1930, when he reported to be medically examined for life assurance. He was found to have a temperature of 102° F., though he felt well. He stated that on January 1st he had had a shivering attack at 1 p.m., but had been able to carry on his work up to the time of examination. After January 7th he was seen daily. Each day about 1 p.m. he had a shivering attack, which passed off after sweating in the evening. The fever was distinctly undulant in character, the diurnal rise increasing and diminishing in a regular way. The temperature chart showed a marked periodicity, waves of five to seven days' duration being noted. The evening temperature, taken in the axilla, varied from 98.4° to 102° F. Sweating was not excessive. For a few days at the commencement of the condition cough was present, occurring only in the afternoon and evening when the temperature rose. The patient thereafter had no particular complaint. He never looked ill, and was always bright and cheerful. At this time Dr. Guy, city tuberculosis officer, seen in consultation, considered that the condition was not tuberculous.

Treatment was symptomatic, the diet being fluid while the fever continued. Cold sponging gave much comfort. Quinine sulphate and quinine hydrochloride were given in doses of 10 grains three times a day. The quinine appeared to have no influence on the height of the temperature, but following its use the onset of the daily rise was delayed from 1 p.m. till 6 p.m. The fever continued till February 16th; since that date it has not recurred, and the patient is again at work after a satisfactory convalescence.

Bacteriological Findings.

The patient's serum, submitted for examination approximately four weeks after the supposed onset of the condition, did not agglutinate *B. typhosus*, *B. paratyphosus* A, or *B. paratyphosus* B. In view of the history, further reactions were carried out with available strains of *Br. abortus* and *Br. melitensis*. The serum agglutinated strains of both organisms in high titre. The emulsions used in these reactions were suspensions in 0.85 per cent. saline of living organisms from forty-eight-hour agar slope cultures.

The results were as follows, final readings being made after eighteen hours in each case.

Strain.	End Titre.
Br. abortus (Bang)	1 in 3,200
Br. abortus (Hog)	1 in 1,600
Br. abortus (Barker)	1 in 3,200
Br. abortus (T)	1 in 6,400
Br. melitensis (stock strain)	1 in 3,200
Br. melitensis (Group II)	1 in 1,600
Br. melitensis (Arkwright)	1 in 800

Agglutinin Absorption.

Absorption of the serum by *Br. abortus* (Bang) removed agglutinins for all strains of *Br. abortus* and *Br. melitensis*. Absorption by the three *Br. melitensis* strains removed only agglutinins for these strains, the same high agglutination titres for *Br. abortus*

being noted after absorption as before. The results of the direct agglutination tests and the agglutinin absorption reactions clearly indicated a *Br. abortus* infection.

Blood Culture.—15 c.cm. of the patient's blood withdrawn on February 5th at the commencement of an evening rise of temperature gave completely negative results.

Urine.—A centrifuged deposit of urine (February 5th) which gave negative results on culture was inoculated subcutaneously into a guinea-pig. The animal was killed after twenty-one days. The post-mortem appearances showed nothing abnormal, and no organisms could be cultivated from the lymph glands at the site of inoculation, the liver, spleen, or heart blood. The guinea-pig's serum agglutinated *Br. abortus* (Hog) in a dilution of 1 in 80, and the *Br. melitensis* strains in dilutions of 1 in 20 to 1 in 40. These findings are inconclusive, normal serum effects being probably sufficient to account for them.

Prior to the onset of the attack the patient had not been in the habit of drinking an unusual quantity of milk. During December, 1929, he visited a farm three times, but did not partake of any milk there. On December 12th he visited Lancashire and had porridge with milk and a glass of milk at Preston, while later in the day he drank milk in Manchester. He returned to Edinburgh the following day. It is of interest that Wilson and Nutt (1926)[2] reported that 8.8 per cent. of mixed milk samples obtained in Manchester contained *Br. abortus*. The source of infection in this case, however, remains obscure.

Points of interest in the case are:

1. The patient had no close association with cattle, and was not in the habit of drinking unusual amounts of raw milk.

2. The apparent physical well-being of the patient even in presence of severe pyrexial attacks.

3. The clean-cut results of agglutinin absorption reactions, pointing definitely to an infection with *Br. abortus*.

4. Spontaneous disappearance of symptoms after the relatively short period of six weeks from the onset of the illness.

A CASE OF ABORTUS FEVER IN NORTHERN IRELAND.

BY

JAMES S. BAXTER, B.Sc., M.B., B.Ch.,

HOUSE-PHYSICIAN, ROYAL VICTORIA HOSPITAL, BELFAST.

THE literature on the subject contains records of seventeen cases of *Br. abortus* infections in man in the British Isles. Sixteen of these have been reported from England and Wales and one from Scotland. The case I wish to record is the second known to have occurred in Northern Ireland, a previous one having been reported to the Ulster Medical Society in February, 1930. An inquiry conducted by the Ministry of Agriculture of Northern Ireland in 1928 revealed the fact that contagious abortion in cattle is widespread in the country and is a very important disease. This being so, it seems remarkable that more cases of *Br. abortus* infection in man have not been recognized in Northern Ireland, which is so largely agricultural.

A farm labourer from County Down, aged 42, was admitted to the Royal Victoria Hospital, Belfast, on January 19th, 1930, as a possible surgical emergency. He gave a history of indefinite malaise about three weeks previously. This had lasted about a week, after which he had fairly severe abdominal pain, with headache, fever, and some diarrhoea. On examination he had considerable flushing of the face with a definite bluish tinge about the lips; the tongue was dry and coated, the breath foul. There was general abdominal tenderness, most marked in the lower half of the abdomen, and an enlarged and tender spleen. The lungs showed some patches of dullness with prolonged expiration about the level of the eighth rib posteriorly. The optic discs were rather hazy in outline. The heart, central nervous system, and urine showed nothing of note. There was a moderate degree of pyrexia (100° F.). The case seemed to be one of enteric infection, but the Widal reaction was negative for *B. typhosus* and *B. paratyphosus* A and B. A radiogram of the chest revealed nothing abnormal.

The patient was transferred to a medical ward for further investigation. The temperature chart showed pyrexia up to about 102° F. in the evening, with a fall of three to four degrees in the morning. A further Widal reaction on January 24th was again negative for *B. typhosus* and *B. paratyphosus* A and B. The lung signs had by this time cleared up, but the spleen remained enlarged and tender. The patient's serum was then put up against *B. typhosus* (O), *B. paratyphosus* C, and *Br. abortus*. Agglutination occurred with *Br. abortus* to a dilution of 1 in 250.

After the initial severe symptoms the patient felt quite well except for moderate sweating in the evening when the temperature rose. Physical examination revealed nothing abnormal except the enlarged spleen, which diminished in size as the illness progressed. A blood count in the fourth week of illness showed: red cells 5,200,000 per c.mm., haemoglobin 99 per cent., white cells 7,300. There was a slight relative lymphocytosis.

In the account of the disease given by Dalrymple-Champneys[1] enlargement of the spleen is stated to be fairly constant, but in the cases reported by Wordley,[2] Bloxsome and Davey,[3] and Norman and Robert Cruickshank[4] no enlargement of the spleen was found. The case reported here showed marked enlargement of the spleen, which gradually diminished as the fever subsided. In Nightingale and Wilson's[5] case no mention is made of the spleen, but probably there was no enlargement noted.

Agglutination of Patient's Serum.

January 26th: 1 in 25 (++); 1 in 50 (++); 1 in 125 (±); 1 in 250 (trace).

February 2nd: 1 in 25 (++); 1 in 50 (−); 1 in 125 (±); 1 in 250 (++); 1 in 500 (++); 1 in 1,250 (−).

February 13th: 1 in 25 (−); 1 in 50 (++); 1 in 125 (++); 1 in 250 (++); 1 in 500 (++); 1 in 1,250 (trace).

It will be noted that the two latter tests show a proagglutinoid zone.

Various attempts were made to isolate the organism. A blood culture incubated at a lowered oxygen tension for eight days was sterile. Samples of bile were obtained by a duodenal tube and plated out on Conradi, blood agar, glycerol agar, and in glycerol shake agar tubes. No growth of *Br. abortus* was obtained from any of these. A catheter specimen of urine inoculated on the same media was sterile.

That this is a case of *abortus* fever seems proved by these facts. There was a febrile illness somewhat resembling an enteric infection, but with no agglutination of the paratyphoid-typhoid organisms by the patient's serum. The patient's serum agglutinated *Br. abortus* in fairly high dilution, and also the patient's occupation brought him into association with cattle.

I am indebted to Dr. S. B. Boyd Campbell, physician, Royal Victoria Hospital, for his kind permission to publish these notes, and to Dr. J. S. Campbell for his advice in carrying out the bacteriological investigations.

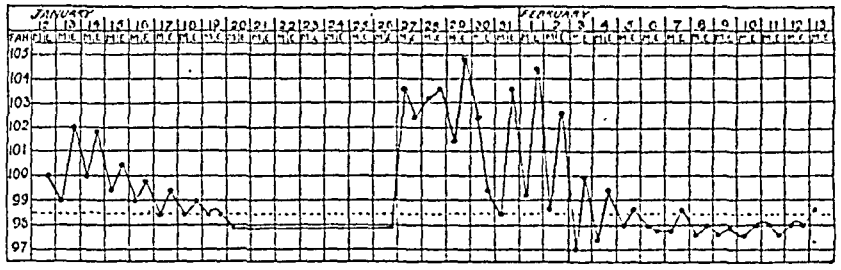
A CASE OF UNDULANT FEVER.

BY

W. S. SCOTT, M.B., Ch.B.,



CHESTER.

THE following account of a case of undulant fever appears worthy of record in view of the diagnostic difficulty and its clinical interest.

A cotton merchant, aged 39, was seen by me on January 12th of this year. He had pyrexia, slight soreness of the throat, constipation, and a white-coated moist tongue, but no other symptoms. During the following seven days his temperature, after reaching a maximum of 102°, fell gradually to normal. As his wife had recently been under treatment for bronchial catarrh succeeding a febrile cold, and as a throat swab yielded a growth of streptococci, the case was diagnosed as a febrile cold associated with a streptococcal throat.

After a few days' apyrexia the patient went to Llandudno for a change, but returned in a hurry with a temperature which

rapidly rose to a maximum of 104.6° on January 29th. The throat had cleared and there was now an entire absence of symptoms except constipation. The striking feature of the case at this time was the general well-being and the alertness of mind despite the temperature—a state of affairs contrasting strongly with the ordinary typhoid picture. The pulse was disproportionately slow in comparison with the temperature. The blood gave a positive Widal reaction for *B. typhosus* up to a dilution of 1 in 150, but was negative for *B. paratyphosus* A and B; in view of the clinical picture I was, however, reluctant to accept a diagnosis of typhoid fever.

At this point I became aware of two facts of which previously I had been ignorant—namely, that the patient kept a herd of Jersey cows, more or less as a hobby, and that he had had cases of *abortus* fever in the herd. One heifer had recently aborted after 7½ months' gestation, and the milk from this animal had been used in the house. On February 4th Dr. Cohen of Liverpool was called in consultation; he agreed that the case was one of undulant fever, and that the possibility of typhoid fever might be ignored, the Widal reaction being modified probably by repeated war-time T.A.B. inoculation.

A further blood test was now performed by Dr. Grace of the Chester Royal Infirmary, with the following results. On three occasions the serum gave an agglutination to *B. typhosus* up to a dilution of 1 in 300; *Br. abortus* was agglutinated twice up to a dilution of 1 in 200; and *M. melitensis* up to a dilution of 1 in 200, using the standardized agglutinable emulsions supplied by the Medical Research Council. A blood count showed: red cells 4,500,000 and white cells 3,750 per c.mm.

The second period of pyrexia lasted for nine days, and up to date (February 13th) there has been an apyrexial period of eight days. The urine and faeces were not examined bacteriologically, nor was a blood culture made. The spleen was not enlarged, and there was no sign of spots or any kind of rash.

The most striking features of the case were the disproportionate slowness of the pulse, the mental alertness, and the state of general well-being despite the high temperature.

Memoranda:
MEDICAL, SURGICAL, OBSTETRICAL.

SURGICAL EMPHYSEMA FOLLOWING DENTAL TREATMENT.

THE occurrence of surgical emphysema of the face and neck as a sequel of dental treatment would seem to be an incident worthy of being placed on record.

On the evening of February 13th I was called to see a young married woman, aged 24, who was complaining of pain and swelling on the left side of her face and neck as far down as the clavicle. On examination I found that the left side of the face from the orbit downwards, and the left side of the neck as far down as the clavicle in front, and the scapula behind were slightly swollen, and on palpation were definitely crepitant, indicating the presence of air under the skin. I learned that a few days before she had had a small apical abscess of the left lateral upper incisor tooth drained through the nerve cavity by her dentist. She had the nerve cavity treated with antiseptics on several occasions, and in the afternoon of the day on which I saw her she had the cavity cleaned and filled. While the dentist was drying out the cavity with hot air she felt a sudden pain just below the left eye, and said her face felt as though it had been blown up by a bicycle pump. Presumably, when the dentist blew the air into the cavity, he must have occluded the opening of the cavity with the end of the instrument, and in this way forced the air up the nerve channel; from this it escaped through the infra-orbital foramen under the skin, and from there spread down the cheek and into the neck. The air took about four days to absorb.

Winchester. C. B. S. FULLER, *M.C.*, M.D., M.R.C.P.

UTERINE FISTULA.
WITH NOTES ON THE TREATMENT OF FISTULAE AND SINUSES.

I DO not know whether the following method for marking out the track of a sinus or fistula has been previously described. It is specially useful for anal fistulae and other similar conditions in which it is extremely difficult to follow all the windings of the track.

The sinus or fistula is first well syringed with sodium bicarbonate solution, 1 drachm to the pint, in order to remove all pus. Aqueous methylene blue solution is then forced in by a syringe, gauze being held tightly round the nozzle in order, as far as possible, to prevent the solution coming back past the nozzle. If the methylene blue solution is forced in properly, all the walls of the sinus or fistula will be coloured dark blue, and it is the easiest thing in the world to follow the track. If, then, everything blue is removed one may be certain that one has cleared out the whole track.

An interesting case I had recently illustrates a further use of this method.

A young woman on whom I had twice performed Caesarean section had some sepsis of the abdominal wall after the second operation. A small abscess formed, which was opened, and the patient left the hospital soundly healed. Seven months later she came back with a small sinus in the middle of the scar, from which she complained that there had been a profuse discharge of blood for three days recently. The bleeding had then stopped. Thinking that it was a stitch abscess I anaesthetized her, and after forcing in methylene blue proceeded to open up the sinus. A piece of silk, firmly attached, was found in the sinus. Knowing that the only silk used at the last Caesarean section was that employed in suturing the uterus, I proceeded to make a vaginal examination to determine the position of the uterus. I then found that methylene blue was coming out of the vagina. The uterus was found to be adherent to the anterior abdominal wall opposite to the opening of the sinus. It had doubtless been anchored there by the sepsis following the last Caesarean section.

The case was then clear—the sinus was a uterine fistula. Subsequent inquiries revealed the fact that she was menstruating at the time of the discharge of blood from the sinus; so this was obviously menstrual blood. I removed the uterus, and the patient left the hospital with a sound abdominal wall.

Reports of Societies.

ETHYLENE ANAESTHESIA.

AT a meeting of the Section of Anaesthetics of the Royal Society of Medicine on May 2nd, with Dr. R. E. APPERLY in the chair, the subject of ethylene anaesthesia was discussed.

Dr. R. J. CLAUSEN said that, although previous investigations had been recorded, the use of ethylene anaesthesia dated from 1923, when Luckhardt of Chicago reported cases. References were more frequent in the literature of the United States and Canada than in that of this country, but the subject was dealt with in a paper by Fairlie of Glasgow at the Annual Meeting of the British Medical Association last year (*Journal*, November 16th, p. 891). The gas, the chemical formula for which was C_2H_4, was colourless, with a characteristic smell, part of which might be due to impurities. It was highly inflammable, and, when mixed in suitable proportions with air, oxygen, or nitrous oxide, was explosive. The speaker's own experience included 371 administrations, 92 of which were for dental extraction, and most of the others in gynaecological cases. With few exceptions McKesson's gas apparatus was used. The longest duration of anaesthesia was two hours twenty-five minutes; in four other cases it was over two hours. The preparation and premedication of the patient followed

the ordinary hospital routine, but the use of preliminary hypnotics was desirable. The technique of administration was the same as that for nitrous oxide, and the same machine might be used. The time of induction was short, probably shorter than with nitrous oxide. The quick and sudden onset of the anaesthesia, with relaxation, had often been commented on by surgeons. The type of anaesthesia resembled that of nitrous oxide, but was deeper and smoother, and the pulse and respiration were as a rule slower. The colour was better, since the oxygen percentage employed was considerably higher, but should an oxygen 'shortage occur, cyanosis might not be so obvious as with nitrous oxide. The maintenance rate for oxygen naturally varied fairly widely in different cases, and to some extent at different stages of the administration. The usual range was from 10 to 15 per cent. as shown on the dial, which on his machine apparently represented from 15 to 30 per cent. of oxygen, the usual amount used being in the neighbourhood of 20 per cent. The consumption of gas averaged about 60 gallons an hour, entailing an oxygen consumption of about 2 ft. per hour, which would bring the cost per hour for hospital use to about 3s. 3d. A 150 gallon cylinder had sufficed for 200 minutes' anaesthesia. Ether had been used, but in small amount, in nearly all abdominal operations in order to give adequate relaxation. Probably with care, and by giving a heavier premedication and longer time for induction, this might be more often dispensed with; but small amounts of ether were as a rule notably more effective with ethylene than with nitrous oxide. In an abdominal operation 3 ounces of ether would be considered a large quantity, and he had exceeded this on only twelve occasions. In 26 abdominal cases, which had lasted for one hour or over, without spinal or local anaesthesia, the amount used had averaged just over 2½ ounces, the duration of anaesthesia averaging 82 minutes. For many minor gynaecological procedures, and for operations for conditions such as hernia, ether should not be required, while for abdominal operations in debilitated persons or those with shock, the amount needed was very small. While he would not claim that some cases under ethylene might not have done better under other anaesthetics, in no case had it been necessary to abandon ethylene for another method. Recovery was quick, almost as quick in the first place as with nitrous oxide, though much longer time was taken for complete elimination of the gas after consciousness had returned. The anaesthesia was followed by quite a prolonged period of analgesia. Convalescence was as good as with nitrous oxide. Although there had been a certain number of deaths in this series, none of them could be attributed to the anaesthetic. One baby which had been delivered by Caesarean section died six hours after delivery, apparently from non-expansion of the lungs, although it had cried quite loudly when born. The drawbacks to the method were the smell, the haemorrhage, and the risk of fire. He dealt with the smell by means of an exhaust pipe leading the expired gases away from the patient, and preferably outside the theatre. Previously to the use of this contrivance the surgeons and theatre staff had protested that they were gassed. The smell of the gas could also be avoided by using a closed circuit with carbon dioxide absorption. Liability to bleeding was somewhat increased with ethylene anaesthesia, even in the absence of any congestion or cyanosis. Many patients, however, bled freely when under ether or even chloroform, so that he did not think ethylene should be condemned on that ground. Finally, there was the danger of fire or explosion, which certainly forbade the use of ethylene in the neighbourhood of naked lights, the cautery, and the diathermy apparatus. Most of the fires and explosions in the United States had been due to such causes, or to static electricity, a phenomenon not met with to anything like the same extent in this country. The only special precaution he had taken was to put a little water into the breathing bag to lessen the remote possibility of static sparks. With reasonable skill and care there should be no chance of ignition from outside.

Mr. C. L. HEWER reported that he had given about 130 administrations. The advantages over nitrous oxide were the better relaxation and the fact that a higher percentage of oxygen could be given. Against this advantage had to be set the drawback of inflammability, the tendency to nausea and vomiting, and the smell. The reason why the textbooks described the smell as faint and ethereal was that when ethylene was freshly prepared in the laboratory it could hardly be smelt at all, but after being kept for 24 hours it gave the characteristic acetylene-like smell which was so unpleasant, and which must be due to an impurity. If the smell could be eliminated ethylene could be used with much more freedom. It was not a drawback, however, from the patient's point of view, for after two breaths he did not notice it, and had no remembrance of it on recovering consciousness.

In the brief discussion which followed Dr. J. BLOMFIELD said he had had a limited experience of the method, and found the smell very unpleasant; Mr. MAGILL remarked that ethylene had no particular advantages, while the smell was certainly objectionable. In reply to a question about his exhaust pipe, Dr. CLAYSEN said that the one he used was long enough to lead from the table to the door or window, but even if it reached only as far as a corner of the theatre the smell was hardly noticeable in a theatre of fair size. He quite agreed that nitrous oxide with a little ether gave much the same effect, but he was of opinion that ethylene with a little ether gave much better results than nitrous oxide with a fair amount of ether.

THE PERINEAL ROUTE IN THE SURGERY OF THE PROSTATE.

IN the Section of Urology of the Royal Society of Medicine, on April 30th, with Mr. F. A. G. JEANS in the chair, an address was delivered by Professor HUGH H. YOUNG, clinical professor of urology, Johns Hopkins University, on the advantages of the perineal route in the treatment of various diseases of the prostate.

Professor YOUNG, after paying a tribute to British urology, said that he had not chosen the subject of his address with any object of persuading British urologists that perineal prostatectomy was superior to suprapubic. The position of suprapubic prostatectomy was too widely accepted and standardized for him to assail it, but it was possible that, owing to the great success which had followed surgery by the suprapubic route, the value of the perineal route in certain conditions had been overlooked. More attention might advantageously be given to operations upon the prostate through the perineum. One of the great reasons why in the early days the perineal route came to be disregarded was the persistence for many years of the practice of median perineal incisions. Operation for stone involved a median incision, which damaged important anatomical and physiological structures, and led not infrequently to serious haemorrhage and continuing incontinence. Perineal prostatectomy thus came to be voted dangerous as an operation, and unsatisfactory in its results. In reaching the prostate from the perineum it was very important to avoid certain structures, and the speaker indicated, with the help of diagrammatic lantern slides, how it was possible to work at the back of the bulb, to avoid entering the sphincter, or unduly damaging the muscular structures, and to penetrate the rectum. One advantage which might be urged for the perineal route was that the anaesthesia was very easily obtained by single injection through the sacral canal. The position of the patient on the operating table was important. One trouble with many operations on the prostate through the perineum was due to the fact that inadequate or imperfect position had been obtained. He had seen operations conducted on a flat table, with no adequate elevation. He exhibited a special table which he had had constructed, and which gave the desired elevation, but added that any usual table could be modified to serve this purpose. The former median incision had given place to a lateral incision, and through an oblique incision on one side the surgeon was now able to perform a much less haemorrhagic and destructive operation. It was important to recognize the landmarks, to avoid injury to the transverse perinaei muscles, and to pick up and divide properly the recto-urethralis muscle. Having divided the muscle close to the urethra, it was easy to push back the rectum. He had used many kinds of incisions, which he illustrated, but the most useful was

the inverted V. In his view, with the perineal operation and with this incision, very much less tissue was dragged through the sphincter, and the sphincter remained in a much more normal condition than after the suprapubic operation. In a fair proportion of cases, operating by way of the perineum, the surgeon encountered calculi which lay external to the hypertrophied portions and beneath the normal prostate. He believed that in many such cases these were not recognized or removed by the suprapubic method; by the perineal method they could be seen and removed completely. Having removed the prostate, or the stone if any was present, the surgeon was prepared for whatever method of treatment might be desirable. His own method was to put in a rubber bag, which had a tube in the centre of it, and could be filled with water or air. This was introduced by a special instrument, pushed into the bladder, and blown up so as to form a tractor which would stop haemorrhage, the bladder being drained by the tube in the centre. This did away with all gauze packing, and afforded good drainage, though it took rather longer to close the wound.

Professor Young exhibited a table of the 58 deaths which he had had out of 1,571 prostatectomies conducted by this method, an operative mortality of 3.6 per cent. The principal causes of death were pneumonia (15), uraemia (7), pulmonary embolism (7), and sepsis (7). Pulmonary embolism was much more common than it used to be, as was evidenced by the figures from, among others, the Mayo Clinic. A study of the necropsies in his own cases showed that the embolism in practically all came from the femoral vein. It had been suggested that the tendency in surgery in recent years to place the patient in a sitting position, especially with the development of new beds in which the back part was elevated, and the knees also were raised, caused a tendency towards stasis in the femoral vein region. Sepsis played an important part in mortality, a larger part than was shown by the figures, for some of the pulmonary embolism cases might be associated with sepsis. About 50 per cent. of the patients had some cardiac lesion, *yet only 8 per cent. of the deaths could be attributed to* the heart. Another table indicated the speaker's fluctuating experience with regard to mortality over a period of twenty years. There were short periods of years when the operative mortality was extremely low or down to *nil* (in one recent period of three years there had been 198 consecutive operations without a death), but the publication of such figures had the result that less favourable cases were sent to him, and therefore the mortality went up again, perhaps even to 5 per cent.

The operation *per se* could not be said to be a serious one, but the complications involved, and the fact that many of the patients were of advanced age, and were veritable "museums of pathology," impaired the results; in both suprapubic and perineal prostatectomies, however, it had been unquestionably demonstrated that the aged could be operated on successfully, and that large masses of material could be removed through operations in regions where haemorrhage was a great danger, with a resultant mortality that was very low. One very important thing to bear in mind in prostatic surgery was the fact that from 20 to 25 per cent. of the individuals who presented themselves with symptoms of "prostatism" had carcinoma. In the Mayo Clinic this figure was 22 per cent. In about one-half of these cases carcinoma was associated with hypertrophy. Fortunately the condition could be recognized early if medical practitioners could be persuaded to include the prostate in routine examinations. There was a remarkable selective affinity between carcinoma and hypertrophy; the posterior lobe of the prostate was seldom involved in hypertrophy, but carcinoma almost always developed in the posterior portion. The operation he had advocated was curative in a large percentage of cases if there was any chance of cure at all. Several patients after such an operation had now been well for from twelve to eighteen years, and, moreover, had urinary control. The speaker said he wished more surgeons would attempt radical operations for carcinoma of the prostate. In cases where the disease had progressed so far that a radical operation for the carcinoma was impossible, and there was retention, he preferred to resect the lateral and median portions of the prostate, knowing that, while the carcinoma was not being eradicated, the obstruction was relieved; he believed that the result was far superior to simple suprapubic drainage. He had applied radium in such cases through the rectum. Urological opinion had been against operative intervention in cases of tuberculosis of the prostate and seminal vesicles; but many years ago, as the result of an extremely careful study of the cases at Johns Hopkins, he became convinced that the abstention policy was wrong, so as far back as 1900 he had been performing an operation which he described in detail, the most important point being the removal of the deeper-lying portions of the vas deferens. The incision was made through Dénonvillier's fascia. Another condition in which the perineal route might justify itself was diverticulum of the posterior urethra. An occurrence which also required urgent perineal prostatic surgery was traumatism of the posterior urethra, and yet another condition only operable, he believed, through the perineum, was recto-urethral fistula; Professor Young described a procedure here which had been successful in 19 cases. In conclusion, he spoke of the value of the phenolsulphonephthalein test, by far the most accurate means of determining the condition of the kidneys and the operability, not only in prostatic cases, but in urinary and surgical cases generally so far as the kidneys were concerned. He added that he was a great believer in intravenous therapy, particularly with mercurochrome, in pyelitis and stasis developing after perineal prostatectomy. He was convinced that intravenous therapy had a great future, since it was possible to bring about by its means the stimulation of antibodies and the serum defence reactions.

The time taken by Professor Young for his lecture was extended by the wish of the meeting. At the close there was no time for discussion, but a very hearty vote of thanks was accorded to him.

CRESOLURIA.

AT a meeting of the Section of Anatomy and Physiology of the Royal Academy of Medicine in Ireland on April 11th, the President, Professor W. R. FEARON, gave a demonstration of the use of external solvents in indicator work, and read a paper on cresoluria. He said that from a specimen of urine which gave an intense crimson colour with concentrated hydrochloric acid, resembling closely the characteristics of urorosein (indole acetic acid), it was found possible to remove small quantities of cresol by distillation. The colour was found to be due to a condensation between cresol and indoxyl, the condensing cresol being either the ortho or the meta form. Pure para-cresol produced colour under the same conditions. The significance of ortho- and meta-cresoluria, as distinct from para-cresoluria, was discussed, and the suggestion was made that these cresols had been formed in the organism from para-precursors by a process similar to the formation of homogentisic acid. Professor W. J. JESSOP asked if the use of strong nitric acid instead of hydrochloric acid would make the production of the pink colour which the President had demonstrated more easy, especially if crude hydrochloric acid was used. He had been working on the production of urea nitrate in urine, and by adding an equal amount of hydrochloric acid to the urine had produced a pink colour, which in many cases was evanescent. He wondered if this was due to the cresols present and if one might expect to obtain the pink colour more easily with nitric than with hydrochloric acid. Dr. A. R. PARSONS said he had frequently used the test for indigo blue in the past, but had never been able to get any very valuable information from it. He thought this test had fallen very much into disuse, mainly for want of an oxidizing agent. He had formerly used a solution of bleached lime, but this did not keep for long, and therefore was not always available when wanted. He had found that when homogentisic acid was added to sulphuric acid a red colour almost like that demonstrated by the President was obtained. The PRESIDENT, in reply, said that nitric acid could be used, but it was extremely easy to overdo the test when using it. He was interested to hear that homogentisic acid produced the red colour, because it showed that this acid took part in the reaction.

Reviews.

RADIUM THERAPY.

WHEN a subject is new or in a state of flux it commonly happens that writers with insufficient experience of its problems rush into print, with the result that the general reader, already perplexed, is faced with the added difficulty of trying to sift the wheat from the chaff. Something of this kind has happened in the production of books on radium therapy, and in the circumstances it is incumbent on the reviewer to choose from among the many works now appearing on this subject those which may be commended to the notice of the medical practitioner. *Radium in General Practice*,[1] by A. J. LARKIN; *Radium and Cancer*,[2] by DUNCAN C. L. FITZWILLIAMS, and *Die Radiumtherapie*,[3] by F. GUDZENT, all attain the necessary standard of merit, and it is pleasing to note that they reflect some uniformity of opinion, though the German author differs considerably from the authors of the American and English books in his method of approaching the subject.

Radium in General Practice forms a complete guide to radium therapy, including its application in general conditions and dermatology. Only nineteen pages are devoted to the important, if theoretical, physics of radium and to the very practical question of mechanics, an allowance which we think might be increased with advantage. In the rest of the book diseases are considered under separate headings, and the author, having given a short description of their pathology, describes the appropriate method of applying radium in their treatment. In America needles, seeds, and metallic surface applicators are used extensively; occasionally the author mentions the use of massive doses at a distance (bomb therapy), but the Columbia paste applicator, so popular in this country and France, apparently does not find favour in the United States. At the end of each section there is an extensive bibliography consisting mainly of American references. The adoption of the term "β-ray screen" in this book for a screen which cuts off beta rays, hard and soft, is a reminder that the nomenclature at present used in this connexion lacks uniformity, a defect which could easily be remedied. Such terms as "unfiltered" and "unscreened" might well be abandoned, because if we ignore the slight radio-activity of certain waters no radium used in medicine is entirely unscreened.

Radium and Cancer is also written entirely from the clinical aspect, the space devoted to the physics, mechanics, and biology of radium treatment being relatively small. As the title implies, the book limits itself to a consideration of new growths, and does not deal with other applications of radium therapy. Mr. Duncan Fitzwilliams describes each screen by its metal and thickness, and this method, though rather clumsy, is definite and informative, and as such to be preferred to the indefinite term "filtered." The procedures considered are chiefly those demanding the use of needles and tubes, but Columbia paste applicators are frequently advocated for surface and distance irradiation. Numerous individual case reports add to the interest of the text, but many of these cases are so recent that the ultimate results must remain in doubt. The work is very clearly illustrated, and though it shows evidence of rapid composition it gives a fair representation of what may be expected from the technique with which it deals. Errors are few, but even if the physical aspect of the subject has to be condensed such a statement as "One per cent. of radium disintegrates in 25 years," which ignores the well-known logarithmic law of degeneration, can scarcely be passed. The subtitle of Mr Fitzwilliams's book is "Curietherapy," a term which also appears in the text. We do not consider this a good choice, for while the Curies deserve all the credit for the first isolation of radium it must be remembered that the previous researches of Becquerel were the real starting-point of the discovery of radio-activity, the renowned Becquerel burn being the first indication of the biological effects of radium, and that ultimately our own physicists, Rutherford and Soddy, supplied the complete interpretation of radio-activity in their disintegration theory. We prefer the descriptive term "radium therapy" for general use.

Die Radiumtherapie, the fifth volume of "Medizinische Praxis" by Grote, Fromme, and Warnekros, is a work of only 106 pages, but in this space Dr. Gudzent covers the subject in a more complete, though less extensive, manner than do the authors of the two books already noticed. More than half the space he devotes to a consideration of the physics, mechanics, and biology of radium application, thereby giving practical expression to his view—which we share—that training in the theoretical aspects of the subject cannot be too thorough if radium is to be used with intelligence. We feel, however, that he gives far too much of his limited space to accounts of the radio-active properties of the waters in certain German spas, and to the description of radio-active compresses and appliances for the irradiation of water supplies. In the chapters on technique, Gudzent describes the applicators in common use in Germany, which, in the main, resemble those used here, and discusses among other subjects the methods of administering massive doses at a distance, and mesothorium and thorium X as sources of radiation.

None of these three books deals adequately with the subject of secondary radiations, perhaps on account of its complexity and the absence of definite data, but the collaboration of a competent physicist in the writing of the preliminary chapters might have served to remedy this defect. Radium therapy is still in the experimental stage, when over-enthusiasm is likely to produce disappointment. The limits of its applicability have not been determined, and the brilliance of immediate results still tends to obscure ultimate failures. These conclusions emerge from a study of the works under review, but the authors do not sufficiently emphasize the fact that radium therapy is valuable not so much because its results are superior to those obtained by other methods of treatment, but because it is easier to apply and not nearly so likely to be followed by mutilation of the patient.

ANKYLOSTOMIASIS.

"At the present time there is no human disease which is more thoroughly understood in every respect—etiology, epidemiology, diagnosis, treatment, and control." These words are used by A. C. CHANDLER in writing of hookworm disease.[4] The author is well equipped both by his training and by experience to write on a subject of which so much has been heard during the last decade, and which has a definite bearing on the sanitary programmes of many parts of the Tropics. After a brief historical introduction there are chapters on geographical distribution, the anatomy and distribution of the adult worms, including the identification of species, the life cycle and mode of infection, epidemiology (environmental and human factors), pathology, diagnosis, treatment, prevention, and control; the relationship of hookworm larvae to ground itch and creeping eruption is described. There follows a useful appendix on technical methods. In the bibliography the author has made no attempt at complete[illegible] but he has included references to all the important contributions made within the past ten years.

One of the dangers of specialization is a tendency to exaggerate the importance of the particular subject studied, the author does not do this. His treatment of his subject is marked by studious moderation, is clear and is well reasoned. It is with some feeling of relief that we see that among natives in endemic areas infection with ankylostoma or necator does not necessarily connote imminent dissolution. Thus in Southern India, he states,

[4] *Hookworm Disease*. By A. C. Chandler, M.Sc., Ph.D. [London:] Macmillan and Co., Ltd. 1929. (6 × 9½, pp. xvi + 241; 22 figures. 21s. net.)

"hookworm *disease* is practically non-existent in most places, and it is in 90 per cent. of the country a negligible *public health problem.*" *Although infection with hookworms* is widespread there, a somewhat similar conclusion was reached in Sierra Leone in 1925 as a result of work *carried out by Gordon and referred to by Chandler.* The clinician who wishes to know how to diagnose and treat his cases will find the methods he requires in this book, *and the sanitary officer whose interest lies in the elimination* of infective larvae, prevention of soil pollution, and protection of the community has abundant facts and measures placed at his disposal. The most important stage of the life-history of the worm from the sanitary point of view is the infective larval one, and it is easier to feel optimistic if the infective larva migrates laterally from the site of dejection a few inches only, if its migration up the soil wall of a latrine is practically *nil*, and if its longevity tests in natural tropical conditions show over 99 per cent. larvae dead in less than six weeks. The author regards the long-distance lateral and vertical migrations and great longevity—hitherto accepted—as based too exclusively on the maximum results obtained in artificial experiments. Migration up *through* soil is easy in sandy loam, three feet being traversed, but the presence of clay interferes greatly with the migration to the surface. The thorny topic of mass treatment is discussed at some length, and the views of Lane and other opponents are given due consideration. Even those of us who dissent on principle from the adoption of mass treatment cannot fail to admit that the author makes a fair case.

The volume can be recommended to all who have to deal with the hookworm problem; it is excellently printed on good paper, and although the illustrations are mostly such as are familiar to us from the older textbooks they are adequate to the purpose of this work.

PATHOGENIC MICRO-ORGANISMS.

BACTERIOLOGY is a subject which is in a state of lively adolescence, and the appearance of a ninth edition of *Pathogenic Microörganisms*,[6] by PARK and WILLIAMS, is to be welcomed as a survey of present development. The whole field of pathological bacteriology is covered with a nice appreciation of what is established as useful in matters of technique and instructive in principles. This aspect is exemplified in the chapter on agglutinins, where serological technique is described tersely yet sufficiently to be a guide to the laboratory worker. Again, intricate detail is handled with skill and judgement when the haemolytic streptococci are discussed. It is noted that these organisms, although derived from various sources, are nevertheless indistinguishable from one another morphologically and culturally, and even when they are grouped serologically and according to their pathogenic derivation, the grouping is still inconstant and overlapping; and attempts to classify the species of the group by the absorption of agglutinins has not been entirely successful, for it has not been found possible to associate a single agglutinative type with a single named disease. The lengthy and disastrous history of "Typhoid Mary" ushers in an account of the unsatisfactory position of the treatment of the typhoid carrier. The authors have found that treatment by vaccine is unsatisfactory, and cholecystectomy is not always successful, although frequently so. In this connexion the advantages of duodenal culture are mentioned. But in New York it is being found that the known carrier, instructed in hygiene and placed on parole, is a relatively small menace to the community. The trend of the volume is the application of theory and practice to public health problems, and the text bears witness to prolonged and critical experience in large bacteriological laboratories. The original work of the authors, and of Krumwiede, whose name appears on the title-page, is mentioned in a number of places, and this is one of the signs that [illegible] is no mere compilation of the work of others, but rather a critical presentation of it. The writing is lucid and [illegible] quickly understood, and the book is well illustrated and

[6] *Pathogenic Microörganisms.* By William [illegible] Wessels Williams, M.D., and Charles Krumwiede. [illegible] Hallock Park, M.D., Anna [illegible] Rede, M.D. Ninth edition, enlarged and thoroughly revised. London: [illegible]illière, Tindall and Cox. 1929. (6 × 9½, pp. IX + 819; 216 figures. 30s. net.)

indexed. References are given in footnotes, and concern largely, but by no means exclusively, American literature. The volume forms a valuable exposition of present-day bacteriology and a most useful book of reference.

Several further volumes have been received of the third edition of KOLLE and v. WASSERMANN'S Handbook of Pathogenic Micro-organisms,[6] which is appearing seriatim, and cannot, therefore, be reviewed at length. A previous note on this publication appeared in our columns on October 12th, 1929 (p. 670). Speaking generally, the standard of these later volumes is well up to that of their predecessors. Part 36 of vol. ii contains articles on agglutination and conglutination, by Professors R. Paltauf and R. Kraus, Dr. St. Kovács, and Professor O. Streng. Dr. R. Kraus also deals with the phenomena of bacterial precipitation, and Professor C. Oppenheimer writes on bacterial enzymes. The Abderhalden test and diagnostic procedures relating to ferments are described by Professor E. Küster. Professor O. Thomsen concludes this volume with an account of blood agglutination and blood grouping. A large proportion of Part 39 of vol. iii is devoted to disinfection and sterilization, the general and physical aspects being discussed by Professor H. Reichel, and the chemical aspect by Professors E. Bürgi and K. Laubenheimer. Professor G. Sobernheim supplies an article on anthrax, while Professor K. Baerthlein writes on typhus fever. Spirochaetosis of different kinds is dealt with in Part 41 of vol. vii, which opens with an account of Weil's disease by Professors P. Uhlenhuth and W. Fromme. Other articles in this volume relate to the spirochaetal diseases of birds and rabbits. Silicosis and dengue are the subjects of an article by Professor R. Doerr, which opens Part 38 of vol. viii, while rabies is discussed by Professor J. Koch, R. Kraus, and Dr. F. Schweinburg. A careful account of acute poliomyelitis is given by Dr. K. Landsteiner. Small-pox and similar conditions are considered in Part 40 of vol. viii, the authors of the articles being Professor E. Paschen and H. A. Gins. Trachoma and other similar infections of the eyes are discussed by Professor B. Heymann and Dr. W. Rohrschneider. Dr. B. Lipschütz writes on molluscum contagiosum, warts, and condylomata. Part 37 of vol. x is largely devoted to technique, and includes articles on methods of examining animals, the bacteriological investigation of water and air, tissue culture procedures, and related topics.

THE ADOLESCENT.

A HOST of books have been written on the subject of adolescence—the period through which we all have to pass and on which we look back with sentimental regret or abhorrence as the case may be, but which still seems to escape our understanding. Drs. SCHWAN and VEEDER have added another to the number and have concentrated on the study of the adolescent's conflicts and escapes.[7] Many books on this subject owe their wide appeal to the fact that they lay down a simple and straightforward system, to which, in the view of the pedagogic ladies who for the most part are the authors of this kind of work, it is necessary to force the adolescent to conform; and if, as generally happens, the result is disaster, that is, naturally, the fault of the adolescent. The chief virtue of the work under review is that it suggests no such system. The adolescent is treated as an individual and his difficulties are discussed from both the physical and the mental aspects. Although they acknowledge the stimulus given to psychological thought by Freud's teaching, the authors are not psycho-analysts, and consider that many things besides sex present difficulties *virginibus puerisque*. Their general view of the psychology of puberty they state as follows: "Adolescence must be looked upon as a dynamic period in which as a result of the rhythm of growth the individual seeks as a biological necessity a position of independence. In this inherently necessary struggle or search he runs against a group of obstacles both within himself, as a result of his earlier experiences,

[7] *The Adolescent: His Conflicts and Escapes.* By Sidney I. Schwab, M.D., and Borden S. Veeder, M.D. New York and London: D. Appleton and Co. 1929. (5½ × 8½, pp. 365. 10s. 6d. net.)

and in the constitution of society as it exists at the given moment. These may be grouped together as environment. This struggle between the urge from within and the environment is the adolescent conflict." Altogether this is a useful book, and if it contains no strikingly original ideas, it is at least free from fads and unsupported theories.

THE ROMANCE OF CHEMISTRY.

IN the preparation of science for the popular palate it seems sometimes to be thought necessary to introduce something of a comic or flippant atmosphere into a subject. By doing so Professor JAMES KENDALL, in his book *At Home Among the Atoms*,[1] suggests that he has introduced a "human" element into the study of chemistry, a subject which might otherwise be repellent to the ordinary reader. Surely Professor Kendall must be wrong in this surmise. Gone are the days when none but students toiled laboriously through comparatively uninteresting details of experiments until they reached the sketchy threshold of Mendelejeff's periodic system, where some sort of order began to appear in chaos. The discoveries of the present century have rendered chemistry intensely interesting; and Professor Kendall himself disproves the idea that it is necessary, in order to attract the public, to label a chapter on chlorine with the fatuous title, "Gentlemen prefer Blondes," or to call oxygen "the working girl." The fascinating paths through which he leads his reader from substances to elements, atoms, and protons and electrons, until he reaches what he is pleased to call Bohrville, are marred only by the occasional irruption of these facetiæ. We refuse to believe that these things are necessary. Otherwise Professor Kendall has produced a most readable and understandable little book on a subject on which clear writing for the untrained mind is difficult; and the brief historical descriptions which he introduces of such men as Priestley and Dalton are excellent. We hope that in the second volume he promises, dealing with the kinetic-molecular theory, Professor Kendall will eschew much of what is described on the book cover as humour, and rely on the intrinsic interest of his subject, and the clearness of his powers of exposition.

NOTES ON BOOKS.

DR. SUNDELL has a panacea for rheumatism, and has written a book of 88 pages on *Rheumatism: A Study of its Nature and Cure*.[2] The panacea is the pyretic treatment, which, by the application of moist heat, induces pyrexia and sweating. Such treatment is undoubtedly of great value in many cases and is not particularly new, but it has led Dr. Sundell to some surprising and sweeping generalizations which, having a germ of truth in them, are none the less misleading. He states that the essential nature of all forms of rheumatism, acute and chronic, is the same, that all forms of rheumatism have a subnormal temperature, a dry skin, and a strongly acid sweat! His insistence on the importance of failure of secretion of lactic acid is a welcome change from the widespread belief in uric acid as the villain of the piece. His chapter on regional diagnosis does not seem to make for clarity of conception, and there is certainly very little novelty to be found in this compilation of symptoms and their significance.

The *Book of Diets*[3] of the McGuire Clinic gives details of the standard diets used in St. Luke's Hospital, Richmond, Virginia, for a variety of medical and surgical conditions. Some such standard list must be prepared, of course, as a matter of routine organization by every hospital or other centre where any considerable number of in-patients are treated. The advantage of publication lies in the fact that information is made available whereby the practices followed by different institutions may be compared with one another to their mutual advantage. The diets described in the present report conform to the well-recognized standards. They are not all applicable, as they stand, to medical treatment in Great Britain, since a good number of the articles of food mentioned are American patent preparations, not available here, though doubtless their English equivalents can be found easily enough. It is a little startling to see raw oysters figuring as the only type of fish allowed in "Post-operative diet No. 2," but no doubt oysters are cheaper, and hospitals far wealthier, in America than in Europe.

The Chemistry and Bacteriology of Public Health,[11] by C. L. DUNN and D. W. PANDYA, is based on the teaching for the first part of the diploma of public health of the University of Lucknow, a course which is recognized as qualifying for Part I of the diploma of the Conjoint Board of England. It contains everything necessary for the practical teaching of the subject as well as serving as a practical handbook for medical officers of health working in laboratories. The scope of the book is wide—wider, perhaps, than is usually needed by students in this country. Nowadays, however, when the D.P.H. is required for many colonial appointments, and when many Indian and Empire students attend courses in Britain, it will be of considerable use to both teachers and students.

The *African Dispensary Handbook*,[12] by Dr. CLEMENT CHESTERMAN of Yakusu in the Belgian Congo, has been written for the use of native medical assistants in Africa. Realizing the rapid development of the auxiliary native medical service in this continent, the author has endeavoured to bring together in a single volume all the instruction and guidance these educated native assistants are likely to require, for this, as he points out, may well be their only book. Accordingly, its subject-matter is divided into four sections; the first consists of clinical notes on medical diseases, the second is on surgical diseases and minor surgery, the third deals with dispensing and the English and French pharmacopœias, while the fourth section is given to laboratory notes and to the equipment of African dispensaries. It is clear that a vast amount of information must be compressed into a small compass with so ambitious a programme as this, and it may be said at once that Dr. Chesterman has succeeded in his endeavour to produce a satisfactory *multum in parvo* on tropical medicine. The book contains a great deal of useful and up-to-date information on a large variety of medical and surgical subjects, while an elementary knowledge of anatomy, physiology, and so forth, is assumed. Writing a foreword for the book, Sir Andrew Balfour points out that it may possibly be regarded as somewhat advanced for the immediate needs of those for whom it is intended, adding that this, if a fault, is one in the right direction. This is a sound criticism, but carries with it the corollary that here is a vade-mecum for ready reference that should be of real service to medical men and others who may have to practise medicine and surgery, for one reason or another, in Africa. To these the book may be cordially recommended.

Mr. J. JAMES, in *Dental Local Anæsthesia*,[13] the thirteenth volume of *Outlines of Dental Science*, deals with the practical aspects of the subject in a brief but clearly written work. Perhaps the chapter on contraindications might have been extended with advantage—for example, the section relating to the heart conditions that must be regarded as a bar to the use of certain anæsthetics. The author rightly insists on the value of injection anæsthesia in conservative dentistry.

The Naval Blockade 1914–1918,[14] by Lieutenant LOUIS GUICHARD of the French Navy, which has been translated and edited by Mr. CHRISTOPHER TURNER, throws a light on national psychology. Though at the time economically but little affected, Germany was obsessed by the feeling that she was a besieged fortress, and accordingly launched her first declaration of submarine warfare, announcing that from February 18th, 1915, any hostile merchant vessel encountered in British or Irish waters, including the English Channel, would be sunk without regard to crews or passengers. On January 19th, 1917, hoping thereby to strike a victorious blow at this country, Germany declared unrestricted submarine warfare from February 1st. In doing so, there were two errors in psychology: first, an underestimation of the vigour of the allied counter-stroke, and, secondly, in not allowing for the attitude of the United States. The result was that on April 6th war on Germany was declared by the United States, and Germany's chief resource was completely dried up.

DIABETES AS A PHYSIOLOGICAL PROBLEM.

OLIVER-SHARPEY LECTURES BY PROFESSOR J. J. R. MACLEOD.

THE first of two Oliver-Sharpey lectures on diabetes as a physiological problem, by Professor J. J. R. Macleod, M.D., F.R.S., Regius Professor of Physiology, Aberdeen, was delivered at the Royal College of Physicians of London on April 29th.

Professor Macleod said he proposed to describe some researches which had been going on in his former laboratory at Toronto during the last few years, and which had, he thought, a direct clinical application. He would relate in the first lecture the clinical history of certain depancreatized animals, and in the second lecture he would turn to the more general question of the control of the secretion of insulin, and the application which he thought this work might have to changes occurring in man.

Depancreatized Dogs.

Two dogs in his laboratory had been kept alive by treatment with insulin for four years after complete removal of the pancreas. The animals remained in excellent condition throughout the whole of the time of observation. Death occurred, in one case on the fifth day and in the other on the sixth day, after discontinuing insulin. There could not be the slightest doubt that both dogs would have survived to the full span of normal life had insulin treatment been continued, and he regretted now that that plan had not been followed. The reason for stopping the insulin for a number of days was to determine the intensity of the resulting diabetes by observing, among other things, the respiratory quotient. It was intended that this observation should be made on the third and fourth days. Unfortunately, a serious fire broke out in the laboratory on the third day, and it took all that day to repair the damage to the respiratory apparatus. The dogs being apparently in perfect condition, it was decided to postpone the respiratory observations to the fourth and fifth days, although the workers knew that they were incurring grave risk of losing the animals from coma. They expected, however, to guard against this by treatment with insulin immediately any definite symptom, such as vomiting or drowsiness, presented itself; these symptoms developed too late to enable the animals to be saved.

The animals showed some very interesting conditioned reflexes. One of them used to salivate very profusely when the attendant, who was quite accustomed during the day to enter the room frequently for other purposes, took up the hypodermic syringe to inject the insulin. The dog knew that the injection of insulin was to be followed by the giving of food, and the lecturer had never seen a conditioned reflex so well established. Both dogs were fat; they increased in body weight during the four years they were under observation. One of the dogs was used during the earlier part of the period for work on the problem of the assay of insulin. This was a difficult problem to work out, and it had been hoped to devise some method by which insulin could be expressed in units of its antidiabetic power, instead of in units of its power to lower the blood sugar, which was the present basis of assay. That, however, for various reasons, did not prove to be a satisfactory method.

Diet of Depancreatized Animals.

Before these two particular dogs came under observation, experiments had been made on several others to determine how long insulin would keep them alive. The first animals were treated with insulin and fed exclusively on meat containing a moderate amount of fat. Although the diabetic symptoms remained completely suppressed, these animals did not thrive; they lost weight seriously, and had to be destroyed after a month or so. It was perfectly evident that they were not assimilating enough food. To overcome this difficulty it was decided to give cane sugar, administering with it a sufficient amount of insulin to take care of the extra carbohydrate. The animals rapidly improved, gaining in weight; two of them were kept alive for eight months, but they could not be kept alive longer. After eight months—and in the case of other dogs after a shorter time—peculiar symptoms of jaundice made their appearance, and nothing could be done to save the animals. The post-mortem examinations in all the five animals which succumbed in this way showed a very fatty liver, the hepatic cells becoming so distended with fat that destruction resulted. It was also noted with animals treated with sugar and insulin alone that the faeces contained very large amounts of undigested muscle fibre and were loaded with fat. It was concluded that the failure of these animals to live must have been due to the absence of any pancreatic juice. The pancreas having been removed, there were no ferments to digest either protein or fat, bacteria alone being available for this purpose. It was decided to mix with the diet of meat and cane sugar considerable quantities of raw pancreas, in the hope that some would pass through the pylorus with its enzymes untouched, and so bring about pancreatic digestion. When this was done the animals regained perfect condition, and the faeces were practically normal. From that time onwards there was no difficulty in keeping the depancreatized animals alive so long as they were placed on treatment with insulin, and on a diet composed of meat, cane sugar, and raw pancreas.

About two years ago at Toronto the use of very easily digested foodstuffs was investigated—casein, for example, with lecithin, instead of fat—with considerable quantities of sugar. Two or three animals were kept alive indefinitely, and Professor Macleod was under the impression that it was possible, as some French observers had maintained, to keep certain animals alive without any pancreatic juice being secreted into the intestine. He did not think, however, that that was the case with all animals. In that connexion it was an interesting possibility that the animals which could survive without raw pancreas were those in which small nodules of pancreatic tissue remained in the walls of the duodenum. One of his research students some years ago had made a very careful microscopic search for the presence of these pancreatic nodules in the duodenal wall and found them in 50 per cent. of the animals he examined. Some of these animals were normal dogs, and others were depancreatized. The pancreatic nodules lay near the ducts; sometimes there might be several of them, usually there was only one. It was difficult to see the duct connexion in every case, but he imagined that there was really such a connexion. If such was the case, this pancreatic tissue would be discharging into the duodenum itself some pancreatic enzyme which might make all the difference in connexion with the survival of the animals. These pancreatic nodules never contained islets of Langerhans. He was aware that there had been some clinical applications of this work, but he did not think it was sufficient to justify the administration of pancreas to the patient in this way.

Pregnancy of a Depancreatized Animal.

Continuing the record of the two dogs which formed the subject of his lecture, Professor Macleod said that in the year after its depancreatization one of them became pregnant; no unfavourable symptoms followed, and no change was made in the diet or in the insulin administered. It was ultimately delivered of six puppies, three being born alive and three dead. Two puppies were left with the mother, and all went well until the day after the birth, when the keeper reported that the dog was behaving in a peculiar fashion and refusing to suckle its puppies. On examining the dog he found signs of hypoglycaemia; the animal showed great excitement, dilated pupils, and so forth. The administration of sugar was quickly followed by recovery. The interpretation which he put upon the circumstance was that the removal of milk in feeding the puppies had lowered the blood sugar to such a level that hypoglycaemic symptoms supervened. Nothing was changed except the giving of sugar immediately the symptoms appeared, otherwise the diet and insulin dosage were kept constant, and the dog returned to normal. This raised an interesting point in connexion with milk fever, which was fairly common in cows. Shortly after this observation it was reported that Swedish observers had seen milk fever associated with very low blood sugar in cattle. The lecturer was doubtful whether milk fever in cattle was always due to hypoglycaemia. There seemed to be a profound disturbance also in the casein metabolism. One very impor-

tant thing was that during the whole of the pregnancy the carbohydrate balance of the dog scarcely changed. That was important, because it indicated that in this animal at least no significant amount of insulin could have been secreted into the maternal organism by the foetus.

In the case of the other dog, the interesting point was the glucose equivalent, which indicated that after complete removal of the pancreas no organ or tissue of the body assumed any power which allowed the animal to deal with carbohydrate. Had there been any vicarious functioning of other organs in this respect the carbohydrate balance in this and several other animals would have been perceptibly altered during the period of observation. In the dog the utilization of glucose, instead of increasing as pregnancy went on, actually, if anything, decreased. There was no evidence that the foetal insulin had in any way benefited the maternal organism. He was aware that that was at variance with one or two clinical observations, particularly some recent important work by Dr. Lawrence at King's College, in the case of a diabetic woman. There were, however, two points of difference between these experiments on dogs and the observations of Lawrence. In the first place, the dogs were completely depancreatized, whereas the patient was in possession of some pancreatic tissue, and, in the second place, the dogs were receiving much more insulin, plus carbohydrate, than the patient. In the light of what was now known, it seemed quite possible that the remaining healthy islets of the mother's pancreas were stimulated to secrete more insulin, and the generation of new islets occurred as pregnancy advanced. It must be admitted that the case brought forward by Lawrence lent support to the view that the foetal secretion of insulin might reduce the symptoms in a diabetic mother.

Value of Insulin in Animal Experiment.

It was curious that there were comparatively few complete records of the whole course of diabetes in depancreatized dogs. The animals had been observed for short periods in order to prove or disprove some hypotheses, but the method had not been very extensively used. It seemed to him that more investigations should be made of this condition, and in this experiment the workers were fortunate, having insulin, in being able to make observations under very much better conditions than had previously been the case. In the previous use of dogs it was necessary to observe the diabetes after the very severe abdominal operation of removing the pancreas. During the period of observation, therefore, the animals were suffering from surgical shock for the week or two in which they survived. They were not merely diabetic, but were recovering from the effects of operative procedure. By using insulin it was possible to get the animals into an excellent bodily condition before the diabetes was experimentally produced by the withholding of the insulin. It was soon discovered that animals behaved; some survived only a few days after the removal of the insulin, others might live for weeks. The two dogs to which he had referred survived removal of insulin for only five and six days, and during that time the diabetes was very intense. Two days after the removal of the insulin the ketonuria was already quite marked. And, more important still, in connexion with the whole subject of diabetes, the relationship between the glucose excreted and the nitrogen excreted was far beyond the usual limits. The collapse of these animals occurred with great suddenness. They died within an hour of the onset of drowziness. The muscle glycogen in both animals was found to be lowered a little; the liver glycogen was considerably reduced, but he had never observed an entire absence of glycogen in a diabetic animal. There was always some glycogen in the liver if the analysis was made immediately. Glycogen was not a storage material for carbohydrates; it was a necessary step—an obligatory intermediate stage—in the carbohydrate metabolism, and Professor Macleod had never yet seen a liver that was completely glycogen-free.

In contrast with the observation of diabetes in fattened animals, the lecturer said that it seemed important to study the course of diabetes in very lean animals which had no excess of body fat. The full results of an observation undertaken by Soskin at Toronto could not conveniently be given in a lecture, but would be published in the *Journal of Nutrition*. It appeared from his tables that when a large amount of protein was being metabolized, some of the sugar failed to be utilized by the organism; the larger fraction of it was excreted. Towards the end of prolonged diabetes in an emaciated animal the respiratory quotient might rise considerably, quite independently of the giving of sugar. Surely this indicated that the animal was relatively making use of more carbohydrate than the amount of this substance which it was producing from other sources—in other words, carbohydrate utilization was running ahead of the new production of sugar.

Tests for Diabetic Remedies.

The only test that the laboratory worker could apply to a remedy offered for diabetes was the ascertainment of its effect on a depancreatized animal. To watch its effect on the blood sugar of a normal animal was useless. It was quite misleading to commend to the medical profession, as a remedy for diabetes, a certain substance solely on the basis that it lowered the blood sugar in a normal animal; the only test was whether it was able to maintain a depancreatized animal in a normal condition. The question still remained how long that normal condition should continue before the substance could be accepted as a remedy. It had been considered that if the animal were kept alive for more than two or three weeks a claim might be made for the antidiabetic power of the substance concerned, but the lecturer's observations had shown that an animal might be able to live for over a month without any treatment. He thought that these experiments by Soskin sounded a note of warning in judging of the reputed antidiabetic power of any remedy. It was not too much to say that before acceptance the remedy should have been able to keep the animal alive for some period like eight or ten months. Whenever a substance had been sent to him for testing he had always endeavoured to ascertain whether it had similar antidiabetic influence to insulin when given to depancreatized animals, and invariably the results had been negative. He had never yet received a sub-tance having anything approaching the action of insulin.

It followed from what he had said that the diabetic organism still retained the power to utilize carbohydrates, although this power was loss. The deterioration in different animals was variable, and it varied even in the same animal from day to day. He would go so far as to state that no foodstuff could be utilized as fuel until it had become converted into carbohydrates. It might be that as yet it was not possible to identify the particular type of carbohydrate; it might not always be muscle glycogen, though most of it was, but there might be in addition a small fraction not at present identifiable by chemical methods.

ROYAL MEDICAL BENEVOLENT FUND.

At a recent meeting of the committee forty-five grants were made, amounting to £975 10s. The following were some of the cases helped.

M.B., F.Ch., aged 51. She started in general practice three months ago, and spent her last penny in buying up the furniture, etc. The rent had been guaranteed by friends for a time. All went well with the practice increased, but the Last broke down in health. Fees owed £5 from tuberculosis. Sanatorium treatment is necessary. Fees owed £5 case will be considered.

M.D., B.S., aged 35. She has had four resident hospital appointments since qualifying last year. Fund voted £25. Further consideration will be given.

M.B., B.S., aged 45, married. Has been suffering from diabetes since 1927; pulmonary tuberculosis developed in 1929. In the past she earned that he gave his services in the case of a friend. Fund voted £25. Case on the books of the Fund on request.

Widow, aged 52, of M.B., Ch.B. Husband served in R.A.M.C. in the He then died of double pneumonia at the age of 49. The widow is left without means and a log of 7 to educate. Fund gave an emergency grant of £5 immediately and a further grant of £25 and will also help as regards the next six months. The R.M.B.F. Could will also help as regards the

Widow, aged 38, of M.B., Ch.B. Husband died recently of tuberculosis. She has been left with practically no means and a boy of 5 education of the boy. The widow previously helped in order to educate. Fund voted a grant of £25 and will also help as regards the at the age of 50, leaving the widow practically penniless and a boy of 5 to educate. Fund voted a grant of £25 and will also help as regards the

Subscriptions and donations are urgently needed in order that the activities of the Fund may be continued and applicants given the help they need. Cheques should be forwarded to the Honorary Treasurer, Royal Medical Benevolent Fund, Chandos Street, Cavendish Square, W.1.

British Medical Journal.

SATURDAY, MAY 10TH, 1930.

UNDULANT FEVER IN GREAT BRITAIN.

REPORTS in our present issue of five cases of undulant fever, occurring in England, Wales, Scotland, and Ireland, testify to the widespread interest in the incidence of this disease—an interest that has undoubtedly been stimulated by Dr. W. Dalrymple-Champneys's recent report[1] issued by the Ministry of Health. Four of the cases were diagnosed on the basis of the agglutination reaction. From the comparatively brief duration of the disease—three to seven weeks—from the mildness of the symptoms, and from the absence, except in one case, of relapses, it is probable that these were due to infection with the bovine type of *Br. abortus*. The fifth case, reported by Colonel W. P. MacArthur and Major J. B. A. Wigmore, presents features of considerable interest. The patient was ill for eight months, and experienced six relapses. The diagnosis was made not only from a positive agglutination reaction, but by cultivation of the causative organism from the urine. The fact that it grew in the absence of CO_2, and that though it was agglutinated both by a serum prepared against a porcine strain and by one prepared against a bovine strain of *abortus* the former was effective at a higher titre, led the authors to conclude that the organism was probably of the porcine type. This conclusion must for the moment be regarded as provisional. Its independence of the presence of CO_2 excludes for all practical purposes the bovine type of *abortus*; but simple agglutination does not suffice to distinguish it from *Br. melitensis*, for many strains of the porcine type of *abortus* are agglutinated by a bovine *abortus* and by a *melitensis* serum to a titre often higher than that registered against the homologous organism. The severity of the infection, the presence of a papular eruption, and the cultivation of the organism from the urine—a finding which is not uncommon in Mediterranean fever, but which appears to be rare in *abortus* fever—suggest very strongly that the infection may really have been due to *Br. melitensis*. Until further biochemical and serological tests have been made, it would be as well to maintain an open mind as to the exact classification of this bacillus. In any case the finding is of great interest, because, so far as we know, neither *Br. melitensis* nor the porcine type of *Br. abortus* has ever been isolated in this country.

The clinical symptoms of the infection caused by the bovine type of *abortus*, which appears to be the common type in Northern Europe, are well enough known to exclude the necessity of recapitulation. It may be remarked, however, that the fever by no means always runs an undulant course, and it is only the severe cases which manifest the frequent tendency to relapse that is so characteristic of Mediterranean fever. In the majority of cases the symptoms are mild, and are often insufficient to confine the patient to bed. It is not until the temperature is taken, and is found to be 102° or 103° F., that the real nature of the infection is suspected. There is, as Hasseltine[2] remarks, probably no other condition in which the apparent well-being of the patient contrasts so markedly with the record of the thermometer. In early typhoid the pyrexia is accompanied by severe debility, while in early pulmonary tuberculosis the general symptoms of disease are often present without any marked elevation of the temperature.

In the diagnosis of undulant fever the simplest method is to test the patient's serum for agglutinins to *Br. abortus*. In order that information might be obtained of the true frequency of the disease it is highly desirable that all Widal serums should be tested against this organism. The extra trouble involved would be very slight. The coagglutination between the three types of Brucella organisms is so marked that there is no necessity for using more than one suspension. Preferably a bovine *abortus* strain should be chosen, and a formolized suspension, killed by heat at 60° C. for one hour, prepared. The serum should be titrated fully, because a pro-zone phenomenon is not uncommon with organisms of this group, and the tubes should be incubated at 55° C. for eighteen hours. A positive reaction at 1 in 100 or over, in the presence of suggestive clinical symptoms, may be taken as practically diagnostic of the disease.

As has been emphasized on more than one occasion, the disease is primarily one of animals. In this country infection appears to occur either by the consumption of heavily infected cow's milk or by direct contact with aborting animals. The frequency of *abortus* infection in cows is known to be high, but no exact figures of its incidence are available. There is, moreover, little or no reliable information about the incidence of Brucella infections of goats and swine. The time seems to be ripe for the institution by the Ministry of Agriculture of a commission of inquiry into the distribution of the disease in animals, and into the value of the various methods that may be used in its prophylaxis.

CAUSES OF NEO-NATAL DEATH.

"THE first quarter of an hour after birth is the most dangerous period of life. Its mortality is as great as that of any subsequent month. No single discovery in medical science or improvement in practice could do more to save lives than would measures to avoid the losses that now occur within a few minutes after birth." With this quotation from Yandell Henderson's paper on the prevention and treatment of asphyxia in the newborn,[1] Dr. J. N. Cruickshank opens his report on the causes of neo-natal death,[2] based on an investigation carried out on behalf of the Medical Research Council at the Glasgow Royal Maternity and Women's Hospital.

Five more or less distinct periods of the child's existence—namely, the embryonic, the foetal or antenatal, the intra-natal, the neo-natal, and the infantile—have to be considered separately. For the purpose of this investigation Dr. Cruickshank made a detailed study of only the intra-natal and neo-natal periods, and his report includes a close discussion of the post-mortem findings in 800 infants who died within twenty-eight days of birth. In 540 cases (67.5 per cent.) of this series death was regarded as being due to conditions associated with delivery—namely, asphyxia livida neonatorum, asphyxia pallida neonatorum, congenital atelectasis, prematurity, or birth injury. Asphyxia livida neonatorum is an exaggeration of the asphyxial congestion which is present in some degree in all infants at birth; asphyxia pallida neonatorum is a state of shock and is often associated with some form

[1] *Journ. Amer. Med. Assoc.*, February 25th, 1928, p. 583.

of birth injury, of which intracranial damage and the haemorrhage that results therefrom are specially important. In many of the cases prematurity was due to ascertainable causes, such as maternal disease, toxaemia of pregnancy, accidental ante-partum haemorrhage or haemorrhage from a placenta praevia, the use of ecbolic drugs, or accidental or deliberate violence; in a large proportion of cases, however, no cause for the premature labour could be found. In the etiology of neo-natal death prematurity is important, inasmuch as it accentuates the effects of asphyxia and atelectasis, and leads also to a greater tendency than there is in the mature infant to the development of certain complications and di-eases of this period—for example, pneumonia and sepsis. In 238 cases (29.7 per cent.) Dr. Cruickshank found that the cause of death was some infective condition acquired either before, during, or after delivery; but in these cases also prematurity and the persistence of asphyxia and atelectasis were important predisposing factors. The common portals of entry for neo-natal infection were the skin and respiratory tract, the gastro-intestinal tract and the umbilical stump only rarely serving as the source of infection. In view of the popular misconception that a large proportion of neo-natal deaths are due to developmental anomalies, it is noteworthy that Dr. Cruickshank found such conditions in only twenty-two cases (2.75 per cent.). Many cases so recorded on account of their cyanosis are, he believes, really cases of asphyxia livida neonatorum. The presence of congenital syphilis was definitely established in less than 1 per cent. of the cases; but other studies and observations have shown that the children of syphilitic mothers are often born prematurely and are particularly prone to develop sepsis neonatorum.

Preventive measures advocated by Dr. Cruickshank include the provision of increased facilities for antenatal examination and treatment, both at clinics and in hospitals, and of a much greater number of beds for the indoor treatment of obstetrical cases; improvement in the education of medical students, graduates, and midwives; improved hygienic and housing conditions, and the avoidance of overcrowding in maternity institutions; the establishment of special clinics for the treatment of cases of maternal syphilis or, alternatively, their treatment at maternity and child welfare centres instead of at the ordinary clinics for venereal diseases; and, finally, the application of physiological methods to the study of the newborn child and neo-natal diseases. In an appendix on asphyxia neonatorum and allied conditions Dr. Cruickshank sums up the main points in the treatment as follows: (1) The avoidance of all violent attempts at resuscitation. (2) Absolute rest, warmth, and quiet. (3) The immediate toilet of the air passages so as to remove mucus, meconium, and liquor amnii. (4) The supply of a mixture of oxygen and carbon dioxide (5 per cent. of the latter) in regulated doses. (5) Reduction of intracranial pressure by withdrawal of cerebro-spinal fluid in certain cases, particularly those with signs suggestive of intracranial bleeding and those in which the intracranial pressure by withdrawal of cerebro-spinal fluid in advance of an adequate fluid intake by means of gavage until the infant is able to feed from a bottle. (7) The toilet of the skin and accessible mucous membranes, and the exposure and movement involved in bathing, should be avoided until normal breathing, colour, and sucking power are attained. Perhaps the commonest error is failure to distinguish between asphyxia livida neonatorum, which is a true asphyxia demanding for its treatment the establishment of pulmonary respiration, and asphyxia pallida neonatorum, in which the predominant element is shock and failure of circulation, due in the majority of cases to birth injury and requiring a treatment in some ways analogous to that applied to surgical shock. In a communication to this *Journal* (December 15th, 1928, p. 1109) Mr. Aleck Bourne summed up the needs of infants in white asphyxia as "warmth, the head kept low, brandy dropped into the mouth—not for any reflex stimulation, which is impossible, but because some alcohol may be absorbed by the mucous membrane—and possibly some stimulant hypodermic, such as ether, coramine, or adrenaline." The very worst treatment for the infant in this state was, he suggested, artificial respiration, whether by violent massage or squeezing of the chest, abdomen, and loins, or by direct mouth-to-mouth insufflation, the only effect of which was, in his view, inflation of the stomach through the oesophagus, and so still further embarrassment of the heart. Such, however, is the tyranny of nomenclature that the practitioner will tend automatically to resort to artificial respiration in the treatment of any condition to which the name "asphyxia" is applied. There is much to be said, therefore, for Mr. Beckwith Whitehouse's contention that the term "white asphyxia" should be eliminated from all textbooks and substituted by the term "foetal shock."

CONGESTIVE HEART FAILURE

CLINICAL medicine has been described as an art aided by applied science. The nature of such conditions as auricular fibrillation has been elucidated by instrumental observations and experiments in the laboratory, but data so derived have then been correlated with some feature such as the character of the pulse, which can easily be recognized at the bedside. A beautiful illustration of the interdependence of clinical observation and experiment, methods, and incidentally of their respective advantages and limitations, appears in Sir Thomas Lewis's lecture on heart failure of the congestive type published in this issue at page 849. He points out that while the manometric method of measuring venous pressure, which has been extensively employed in his wards, cannot be widely adopted in ordinary practice because its application entails puncture of the vein, clinical investigations extending over many years have led to the discovery of bedside tests which give the same information and can readily be carried out by any careful observer. Lewis's account of the signs of congestive heart failure —a phrase he prefers to "loss of compensation" or "decompensation"—shows how much may still be learned from a careful study of the venous manifestations not only in cases of loss of cardiac tone, but in persons enjoying normal health. Thus, distension of the external jugular veins and a venous pulse at the root of the neck are normal in the supine subject, and the latter is not pathological even when it shows a considerable excursion. Clearly, then, for the recognition of changes pointing to cardiac failure it is important to be familiar with the normal variations in the state of the veins due to the influence of posture.

The main symptom of congestive heart failure is breathlessness unusual to the individual; this breathlessness may increase progressively or, as is commonly, by definite stages, at first being induced by such exertion as walking uphill, but passing as dyspnoea at rest, which becomes more distressing as venous engorgement advances. While in such cases little can be gained by repeated auscultation of the heart—for signs so obtained rarely change, nor do they indicate improvement in the state of the circulation

or the reverse—the venous phenomena and the condition of the liver provide evidence of the greatest value in the detection of the early stages of congestive heart failure. As the degree of engorgement in the venous system increases, distension of the veins extends higher and higher up into the neck, and eventually it persists when the head and shoulders are lifted from the supine position. This rise of the venous zero level, which in the normal subject is near the lower border of the manubrium sterni, should be investigated as a routine in all cases of suspected cardio-vascular disease, for though the gauges of venous zero level are perhaps not as accurate as manometric estimations of the venous pressure, they give results exact enough for bedside diagnosis. It is important to distinguish the normal pulsation of the veins at the root of the neck in the supine subject from that which occurs in venous engorgement. In cases of congestive heart failure the veins may be too tense to pulsate if the patient is in the supine position, but their pulsation can be brought out by raising him to the erect position, whereby the level of zero venous pressure is lowered and the pulsation may spread to the arms and even to the forearms. Usually enlargement of the liver does not precede distension of the cervical veins, but appears and advances synchronously with this phenomenon.

Sir Thomas Lewis insists on the importance of correlating these signs and of not trusting to any one sign in the diagnosis of early congestive heart failure. Thus, distension of the veins on one side of the neck points to local obstruction; but the association of an enlarged liver with distended veins is significant in the diagnosis of early congestion. Similarly, from the fact that general venous engorgement is always accompanied by breathlessness, either at complete rest or upon very slight exertion, it follows that if in a case thought to show early signs of venous stasis breathlessness is absent, the opinion first formed must be revised. Sir Thomas Lewis, clearly though he sets out his arguments and deductions, does well to warn us that their practical application is not as easy as might be supposed. This demonstration of what careful clinical study may reveal will be regarded by many readers as an interesting corollary to the paper on research in medicine which he contributed to our issue of March 15th last.

SIR JOHN BLAND-SUTTON.

The Story of a Surgeon,[1] by Sir John Bland-Sutton, is not only an account of the author's professional career and experiences, it is a brief history of surgical progress during the past fifty years and of the questions which from time to time came into the foreground. It would be well if a book of this kind were published by a leading surgeon in every generation, for without such accounts we are in danger of forgetting momentous events in the history of surgery which should have their lessons for succeeding generations. How many among us to-day realize the prolonged struggle that was made by conservative surgeons and gynaecologists of the mid-nineteenth century against the development of abdominal surgery, especially such proceedings as oöphorectomy? In overcoming this resistance Bland-Sutton took an active share, and his works and writings largely determined the result. Convinced that Lawson Tait was in the right he supported his contentions, but he admits that "Tait was a quarrelsome fellow, rough and rude," and that his statistics were certainly unreliable. When in the same year, 1896, Bland-Sutton was appointed surgeon to the Chelsea Hospital for Women, and to the Middlesex Hospital, his work spoke for itself, and to him is largely due the recognition accorded to the advance of abdominal surgery in England which dates from that period. Better known is the opposition which Lister's doctrines had to overcome in London. Of this Sir John writes: "The opposition to the gospel of antiseptics was astounding—almost unbelievable." At the Middlesex Hospital "Hulke openly sneered at antiseptics, but discreetly used carbolic lotion. The senior surgeon, Nunn, openly laughed at antisepsis." When the author was appointed assistant surgeon, forty-four years ago, he soon incurred the displeasure of his colleagues by his zeal for abdominal surgery, especially in regard to pelvic operations on women. His interest in this field was started by his work in the prosectorium of the Zoological Society, as a result of which he published an article on cysts of the ovaries in animals, which brought him into communication with Alban Doran and Lawson Tait. Further researches culminated in the Jacksonian Prize Essay of 1882 on diseases of the ovaries and uterine appendages. Though surgery has been his object in life, the early interest in comparative anatomy and pathology never flagged, and a great part of the charm of this book arises from the fact that its author is a lover of Nature. Sir John has obviously laid to heart the Shakespearian dictum that "Home-keeping youth have ever homely wits." His nimble wit has no home moss upon it, for he has taken his holidays far afield for many years, and wherever he has been he has stored up knowledge of the peculiarities of men and beast and bird, and recounted them with humorous appreciation of this strange world. It is surprising to note that at the beginning of the war the rank and duties of a captain R.A.M.C.T. (which rank he had held since 1906) were all that the authorities saw fit to offer to such a brilliant and famous surgeon. At the 3rd London General Hospital he rose in course of time to the rank of major. A work more worthy of his abilities was found for him in the organization of the War Museum now housed in Lincoln's Inn Fields. In 1918 he went as correspondent of the *Morning Post* across the Atlantic in order to collect for the public some records of the dangers and difficulties surmounted by the convoy service. Even here his surgical skill was called for, and he was equal to any emergency, from the castration of the bosun's cat to abdominal section. In fine, Sir John strikes us as one

> "That ever with a frolic welcome took
> The thunder and the sunshine."

Almost at the same moment as his book came from the publishers we received the April number of the *British Journal of Surgery* bearing the imprint on its cover, "Birthday Number dedicated to Sir John Bland-Sutton." The frontispiece is an excellent reproduction in colours of the portrait of Sir John in his robes as President of the Royal College of Surgeons of England, from the painting by John Collier which now hangs in the entrance hall of the College. All those who have seen the portrait will agree that it is a life-like presentment. The dedication is as follows: "To Sir John Bland-Sutton, Baronet, first President of the Association of Surgeons of Great Britain and Ireland, this number of the *British Journal of Surgery* is dedicated, on the occasion of the seventy-fifth anniversary of his birth on April 21, 1855." The commemorative issue is worthy of the occasion: it is full of good matter, well presented, and admirably illustrated. There was a time early in his career when it seemed doubtful if Bland-Sutton would stick to pure science and the study of comparative pathology, or become one of the leading operating surgeons of his time. He decided, fortunately for his many patients and the art of surgery, in favour of the latter course; but he has never ceased to be interested in zoology and comparative anatomy and pathology, and his occasional papers on these subjects in the columns of the *British*

[1] *The Story of a Surgeon*. By Sir John Bland-Sutton, Bt., F.R.C.S., with a preamble by Rudyard Kipling. London: Methuen and Co., Ltd. 1930. 12s. 6d. net.

Medical Journal have always been welcomed by our readers, who will join with us in wishing him many happy returns of the recent anniversary, and many further signs of his ability to charm us with discussions on the nature and the ways of living things, and the lessons to be learned from the post-mortem room.

HEALTH OF THE NAVY.

THE Admiralty continues to accelerate publication of its statistical reports of the health of the Navy; and the appearance of the report for the year 1928, little more than six months after that for 1927, encourages a hope that the 1929 report may be published before the end of the present year. The ratio of disease and injury shows progressive decrease. In a total force of 90,620 the ratio was 445.99 per 1,000 in 1928, as compared with 479.05 in the previous year; and though last year's influenza epidemic will probably be found to have increased the ratio in the next report, the comparison with the five years' average should remain satisfactory. The average daily sick list was 19.44 per 1,000, compared with 20.55 in 1927; and the 646,211 days of sickness represented 7.11 days per head of the total force, a decrease of 0.66 in comparison with the five years' average. This figure of slightly more than one week's sickness for each individual may have some interest for those who are responsible for the payment of sickness benefit in civil life. The lowest sick rate was in the Atlantic fleet; the highest in the Irregular list. During the year 1,037 persons were "finally" invalided, a ratio of 11.41 per 1,000, representing a decrease of 4.23 on the five years' average, and of 2.39 as compared with 1927. Twenty-eight of the 1,037 were invalided on account of having refused surgical operation; and it is interesting to speculate on what happened to the two patients with appendicitis who declined operation, and on the motives of the man with insufficient teeth who refused dental treatment, and of the man who preferred to carry multiple corns and hammer toes with him into civil life. The chief causes of invaliding were diseases of the eye (in the majority of cases errors of refraction), pulmonary tuberculosis, diseases of the ear, wounds and injuries, and diseases of the heart. Neurasthenia accounted for 38 invaliding, and 37 of the invalided had "deformities of the limbs." The 202 deaths in the force represented a rate of 2.22 per 1,000. Of this total rate 0.58 resulted from injuries, burns, and scalds; 0.21 from tuberculosis; 0.16 from pneumonia; 0.16 from diseases of the intestine; 0.15 from suicide; 0.12 from drowning; and 0.12 from organic heart disease. Tuberculosis, therefore, still maintained its place as the chief medical cause of death; and while the eleven cases of drowning were less than half those of the previous year, the cases of suicide were doubled—namely, fourteen. In 19,000 vaccinations and revaccinations there were 3,400 failures, and 394 of the vaccinated required nearly a week's treatment each for cow-pox. Three cases of small-pox occurred, all on the China station, with one death. Only three cases of enteric fever were recorded, with one death. There were four cases of paratyphoid. The 6,175 cases of venereal disease, while representing a decrease in case ratio of 8.19 as compared with the five years' average, showed an increase of 1.07 relative to 1927. The Africa station had the highest ratio, the Atlantic fleet the lowest. The total number of days lost from this cause was 142,779, and the average number of men sick daily was 390. The 3,798 acute gonorrhoeal cases were cured on the average in nineteen days. The preventive measures adopted in the Navy are described in the report under the headings: lectures, early diagnosis and treatment, physical and recreational training, and local disinfection. For the last-named procedure no prophylactics have been found superior to calomel cream and potassium permanganate. Dental treatment was required by 96.3 of the finally entered recruits in 1928, as compared with 95.67 per cent. in the previous year. An examination of 983 ratings serving in H.M.S. *Ramillies* showed that 36 per cent. were dentally fit, 59 per cent. required surgical treatment, and nearly 5 per cent. required denture work. Lectures on the care of the teeth are delivered at training centres; and very few cases of neglect, it is stated, are now met with among the younger personnel. To similar lectures at other shore establishments and on some of H.M. ships, at which attendance is voluntary, is attributed a marked diminution in the number of ratings suffering from dirty and neglected mouths. At the Royal Naval Medical School, Greenwich, research work was continued in 1928 on the development of antitoxin immunity. The whole of the hospital school was Schick-tested; and as the result of the use of prophylactics clinical diphtheria ceased to appear, and the carrier rate dropped. In fact, according to the report, it seemed as if the prophylactic procedure adopted had finally banished diphtheria from Greenwich Hospital School, where for years it had caused a 4 per cent. morbidity. In accordance with the recommendation of the Joint Medical Services Committee, the report furnishes information on the incidence of tuberculosis in relation to tropical service and to tropical diseases. The information does not seem particularly noteworthy. It is more interesting to learn that among the 153 cases of pulmonary tuberculosis which occurred during the year, in only eleven was a definite tuberculous family history obtained.

EPHEDRINE.

EPHEDRINE is a drug that in recent years has established and increased its importance very rapidly, and to-day is finding extensive and varied clinical applications. The history of the introduction of ephedrine into therapeutics is curious in that the drug was known for a long time before it received serious attention, but once it attracted notice its virtues were recognized very rapidly. The plant ephedra had been used in Chinese medicine for no fewer than 5,000 years, and the alkaloid was isolated as long ago as 1885. Some of the pharmacological actions of ephedrine were recognized at that date, and as a mydriatic it found a place in Merck's catalogue in 1896. The more important actions of ephedrine were not recognized until 1924, when Chen and Schmidt made a fresh analysis of its actions and showed that these resembled those of adrenaline, but that ephedrine possessed two important advantages—it was active when given by mouth, and the action produced was much more prolonged than was that of adrenaline. Western medical science took a long time to recognize the virtues of ephedrine, but this neglect has since been fully atoned, and the volume of literature devoted to this drug since 1924 has been embarrassingly large. Chen and Schmidt have performed a useful service in summarizing this great mass of information in one of the well-known Medicine Monographs. The bibliography at the end of the monograph is the best testimony of its need, for it contains about 400 references concerning the drug. The great majority of which are recent. The authors give a full account of the evidence concerning the chemistry, pharmacological action, and therapeutic uses of ephedrine. They conclude that those of its actions which are of therapeutic importance are sympathetico-mimetic. The chief of these actions are the pressor action on the circulation, the production of vaso-constriction in mucosa, and the relief of bronchial spasm. On the other hand, many of the pharmacological actions of the drug differ from those produced by adrenaline—for example, it stimulates isolated gut muscle, it stimulates the central nervous system, it does not depress secretions, and it has only a slight action on the basal metabolic rate. The outstanding therapeutic effect produced by ephedrine is the relief of asthma.

[1] Chen and Schmidt: *Ephedrine and Related Substances*. Medicine Monographs. Baltimore: Williams and Wilkins Company, February, 1930.

Miller in 1925 discovered its value for this purpose, and references are given to about 30 authors who have obtained favourable results. The action of ephedrine is slower and less dramatic than that of adrenaline, but it produces relief in about 20 to 30 minutes when given by mouth, and administration two or three times a day often suffices to keep patients free from attacks. The drug has also been used with success in the treatment of hay fever both when given orally and when used as a nasal spray. Nasal sprays of ephedrine (3-5 per cent.) produce almost immediate shrinkage of the engorged nasal mucous membrane, and this effect has been found favourable in the treatment of colds, and also has been utilized in nasal surgery. The action of the drug in raising the general blood pressure has been found useful in spinal anaesthesia, and it is claimed that its use can prevent a fall of blood pressure in this condition. It has also been used with varying success in a large number of other conditions, including various skin diseases and dysmenorrhoea.

MEDICAL EDUCATION IN AMERICA.

THE fourteenth series of *Methods and Problems of Medical Education*,[1] which the Rockefeller Foundation has since 1924 brought out and generously distributed to interested departments and teachers, is mainly devoted to accounts of the methods of recording observations. In this instalment the first of the three articles is by Dr. Charles L. Scudder and Dr. Nathaniel Allison, who reproduce all the sheets, forms, and charts which might possibly be employed for the record of any kind of fracture at the special department for the treatment of fractures in the Massachusetts General Hospital, Boston. This fracture service, established in 1911, is most carefully and elaborately organized, special attention being directed to following up the cases. In his description of the Department of Public Health and Preventive Medicine at the Peking Union Medical College Professor John B. Grant begins with some historical remarks, starting with Pettenkofer, and later on quotes with appreciation Sir George Newman's opinions on the general practitioner's part in preventive medicine. The instruction at the Peking Union Medical College is outlined, and the field-work of the clerkships is supplemented by an appendix giving the forms used for drawing up reports. In the remaining article Drs. Benjamin Hoyer and A. Graeme Mitchell set out the details of the record system at the Children's Hospital, Cincinnati, Ohio. The fifteenth instalment of this series[2] contains an account of Albany Medical College, which is the medical department of Union University, New York. A general account of the department is given by the dean and associate professor of medicine, Dr. Thomas Ordway, and after a description of the hospital by its superintendent, Dr. J. G. Copeland, the features of the fourteen departments of the medical college are set out, with many illustrations by the professors in charge. The Albany Medical College was incorporated in 1839, became part of Union University in 1873, was organized for teaching on a university basis in 1915, and in 1927 was provided with a new school building and a reconstructed hospital. The original hospital, opened in 1851, was very small, but the new hospital, with its eight floors, has 525 beds, and is connected to the medical college by corridors. There is a single department for physiology and pharmacology, a separate one for biological chemistry, and one for pathology and bacteriology. In his account of the Department of Communicable Diseases Dr. A. Sautter, clinical professor of dermatology and contagious diseases, briefly discusses the relative advantages of the cubicle system and of the separate corridor plan in the treatment of communicable diseases. The teaching of radiology, previously consisting of one hour's lecture, followed by the presentation of problem cases which are solved by the students, on one day a week throughout the third year, has been extended; in the fourth year, groups of four students will spend three hours on four days in each week for six weeks in various aspects of radiological work.

SQUINT IN CHILDHOOD.

IN the last annual report of the school medical officer for the county of Lanark[1] there is a contribution by Dr. Ernest Thomson on squint in children. During a period of three and a half years some 1,800 children were referred to him for examination by the school medical officer; of these no fewer than 510 were squinters. Records were kept of the progress of these children under treatment. For various reasons only 383 were straightforward cases of ordinary convergent squint. At the end of the period under review the results of treatment were as follows: 73 children passed the severe test of being completely free from squint at the time of last examination, which varied from 4 to 24 months after the first examination. These children had straight eyes whether the glasses were on or off, but it is not suggested that relapse would not occur if the wearing of the spectacles were to be given up. A second group of 110 children showed no detectable squint so long as the spectacles were being worn, though the squint would return if the glasses were removed, and also during illness or excitement. There were indications that many of these children would eventually attain the state of the first group. A third group of 102 cases consisted of those in which the squint was noted as improved or lessened in degree. The fourth group, also of 102 cases, showed no improvement in the state of the squint. It was found that well over half the children in this group did not fulfil the conditions for successful treatment, because either the squinting eye was amblyopic or the spectacles were not conscientiously worn from morning till night. Others were of the alternating type, a condition which is notoriously difficult to cure. The moral drawn from these observations is twofold: the earlier a squint is treated optically the better are the results; imperfectly carried out treatment is little better than no treatment at all. The true ideal, unattainable perhaps, is prevention of the occurrence of squint by the examination of all children for errors of refraction at an early age.

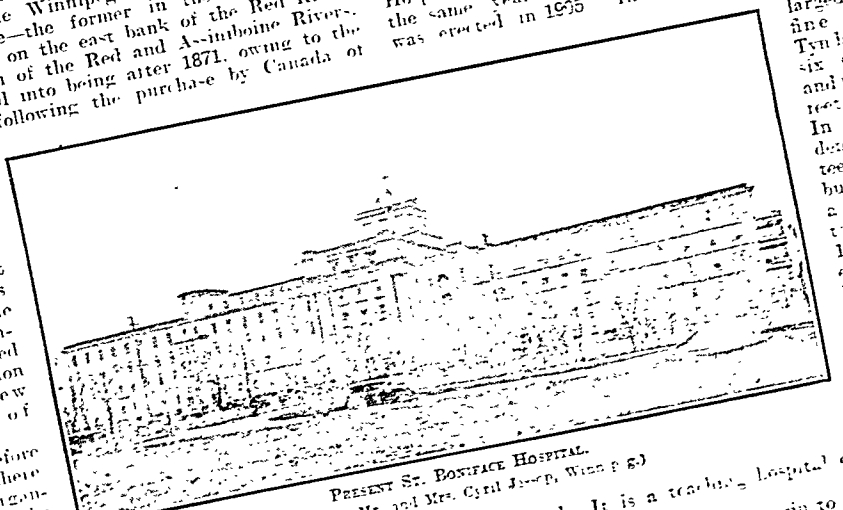
CONGRESS FOR SEX RESEARCH.

As previously announced, the second International Congress for Sex Research will be held in London in the House of the British Medical Association, Tavistock Square, from August 3rd to 9th next. The preliminary programme provides for general meetings, to be held in the mornings, at which problems of present interest will be treated in a number of reviews by prominent workers. The afternoons will be devoted to discussions on the general papers, and sectional meetings. The following are some of the subjects which will be discussed at the general meetings in the mornings: puberty and maturity; problems dealing with the physiology of the sex glands; hormone therapy. The rulings laid down by the committee restrict membership to professional biologists engaged in research on, or teaching in accredited institutions, anatomy, anthropology, botany, medicine, physiology, psychology, sociology, veterinary science, or zoology; to members of the medical profession now practising or who have practised. All British scientists or medical men who wish to take part in the congress are invited to apply to the congress secretary, Department of Animal Genetics, King's Buildings, the University, Edinburgh.

WE regret to announce the death on May 5th, after a short illness, of Dr. H. J. B. Fry, pathologist to the Research Institute of the Cancer Hospital, London.

NINETY-EIGHTH ANNUAL MEETING of the British Medical Association, WINNIPEG, 1930.

BANK OF MONTREAL.
(Photo by P. McAdam, Winnipeg.)



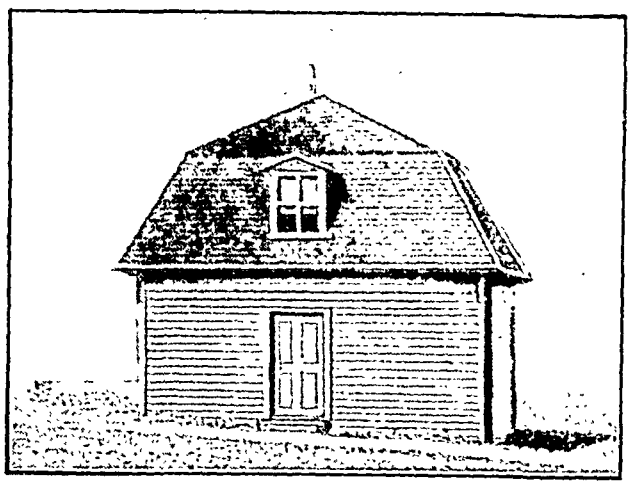
AT the invitation of the Canadian Medical Association the ninety-eighth Annual Meeting of the British Medical Association will be held at Winnipeg next summer, under the presidency of Professor W. Harvey Smith, who will deliver his inaugural address on Tuesday, August 26th. The scientific and clinical business of the meeting is being organized in fourteen Sections, which will hold their sessions on Wednesday, Thursday, and Friday, August 27th, 28th, and 29th, the mornings being given up to discussions and the reading of papers, and the afternoons to demonstrations and special addresses. The names of the Officers of Sections, with other preliminary notes, are published in this week's *Supplement*, and further details of the arrangements will appear from time to time in later issues. Members who propose to take part in the meeting should write at once for particulars about the journey by sea and land to the Financial Secretary and Business Manager, B.M.A. House, Tavistock Square, London, W.C.1. We publish below the fourth of a series of historical and descriptive articles on Winnipeg and its institutions, contributed by Dr. Ross Mitchell; the first appeared on January 4th (p. 32), the second on February 15th (p. 300), and the third on March 22nd (p. 556).

THE HOSPITALS AND NURSING SERVICES OF GREATER WINNIPEG.

ST. BONIFACE HOSPITAL.

Two hospitals in Greater Winnipeg stand out with respect to age and size: the Winnipeg General Hospital and Hôpital St. Boniface—the former in the west end of Winnipeg, the latter on the east bank of the Red River, opposite the junction of the Red and Assiniboine Rivers. Hospitals were called into being after 1871, owing to the influx of settlers following the purchase by Canada of Rupert's Land from the Hudson's Bay Company, and the coming of Lord Wolseley's expedition to quiet the disturbances incident to the change of government necessitated by the creation of the new province of Manitoba.

Even before that date there had been organized care of the sick. At midnight on June 30th, 1844, four sisters of the Grey Nuns of Montreal arrived at St. Boniface in a bark canoe. Almost from the time of their arrival they entered upon their duties of teaching orphans and caring for the sick. Their proper title is Les Sœurs de la Charité de l'Hôpital Général de Montreal, but from their costume they are commonly known as the Grey Nuns. In 1871 they had managed to acquire sufficient funds to build a hospital which would accommodate four patients. In 1877 they acquired a large house which could accommodate ten patients. The demand for beds increased so rapidly that ten years later the corner stone of the present hospital was laid. The first building was of brick, and measured 80 feet by 40 feet. In 1893 a transept 140 feet by 50 feet was added. St. Roch's Hospital for infectious diseases was established in the same year. A south wing 223 feet by 35 feet was erected in 1905. In 1917 the central part of the building was enlarged. It has a fine front of Tyndall stone, is six stories high, and measures 167 feet by 52 feet. In 1927 a residence for fourteen interns was built. In 1928 a nine resident to accommodate 166 nurses was erected, and in 1929 a still further addition to the hospital was made. At the present time the hospital contains six hundred beds, and is completely equipped. It is a teaching hospital of the University of Manitoba.



PRESENT ST. BONIFACE HOSPITAL.
(Photo by Mr. and Mrs. Cyril Joseph, Winnipeg.)

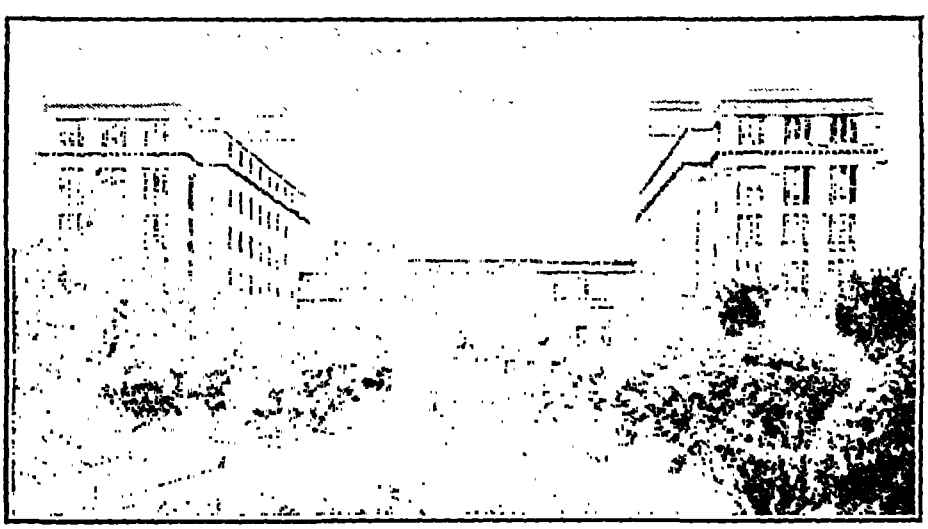
The Grey Nuns owe their origin to the Venerable Marie-Marguerite Dufrost Lajemmerais (Madame d'Youville) and the Rev. Louis M. Normand du Faradon, one-time Superior of the Seminary of St. Sulpice of Ville Marie, now Montreal. The order was founded in 1738, when the first city of Canada was little more than a village nestling on an island at the edge of a limitless wilderness.

THE WINNIPEG GENERAL HOSPITAL.

The Winnipeg General Hospital is junior to St. Boniface Hospital only by a short time. In 1871 a meeting was called by Lieutenant-Governor Archibald, and among those who attended were the Hon. A. G. B. Bannatyne, the Hon. Alfred Boyd, and Dr. J. H. O'Donnell. At this meeting a Board of Health was formed, and steps were taken to begin hospital work immediately.

On December 13th, 1872, the Winnipeg General Hospital was organized, but it was not until May 14th, 1875, that provincial letters of incorporation were taken out, a step rendered necessary by an appeal to the Provincial Government for assistance.

FIRST ST. BONIFACE HOSPITAL (1871).



The first building occupied by the hospital was situated on the north-west corner of McDermot and Albert Street. This building had been occupied only two or three months when the hospital was moved to a house somewhere in the rear of the present Bank of Montreal, and afterwards to one on Notre Dame Avenue, owned by the late Dr. Schultz. From there it was moved to the bank of the Red River at a point south of Broadway on the present location of the Canadian National Railway. In 1875 the hospital was removed to Main Street North, to property owned by the late Hon. John Norquay. The sixth move was to a home owned by the hospital between Bannatyne and McDermot, close to the present location on land donated by the late A. G. B. Bannatyne. This location was selected with a view to placing the institution in that portion of the city which would most centrally meet the needs of the future, and the site chosen proves the wisdom and forethought of those responsible for the conduct of the Winnipeg General Hospital in the early days. The buildings erected accommodated sixteen public ward patients and four private patients, and had a small operating room.

With the beginning of the C.P.R. construction the large influx of settlers soon made the need for much greater accommodation apparent, and while arrangements were being made to collect funds for extensions the hospital was moved to the Dominion Government Immigration Hall on Point Douglas Common. It was decided that the lot that had been donated to the institution by the late A. G. B. Bannatyne and A. McDermot was not large enough, and this was exchanged for a block to the west of Olivia Street, and the adjoining block was purchased from the executors of the McDermot Estate for $5,000.00. On this a building costing $65,000 (£13,000) was erected and formally opened in 1884. The preponderance of males among the patients showed that Winnipeg was still a pioneer city, the proportion of males to females being ten to one.

A Nurses' Home and Maternity Department were added in 1888, and the Isolation Hospital was built in 1892. The growth of the city soon made further accommodation absolutely necessary, and in 1897 arrangements were made for the erection of a surgical wing, which was opened in 1899, and in 1904 a wing was erected at the east end of the medical building and the administration portion was remodelled.

In 1906 Bannatyne Avenue in front of the hospital was diverted to form a crescent so as to increase the site of the hospital, and the vacant square to the north was converted into a park, which provides a pleasant recreational area for convalescent patients. The full tide of immigration into the West between 1910 and 1912 was reflected in the expansion of the General Hospital at that time. New buildings, shown in the illustration, and providing accommodation for 250 beds, were completed in 1913.

The Winnipeg General Hospital was the first Canadian hospital to organize a social service department. This was in 1910. In 1919 a psychopathic ward was opened, and in 1922 an additional nurses' home. The first graduating class of nurses wrote their examinations in 1889. Since that time over 1,100 nurses have graduated from the hospital training school. The Medical College, which houses the Medical Faculty of the University of Manitoba, lies immediately to the west, and is connected with the hospital buildings by an underground passage. The General Hospital is practically the University hospital, and during its fifty years' existence more than 850 graduates in medicine have passed through its halls. These largely provide the medical service for Western Canada.

WINNIPEG GENERAL HOSPITAL.
(Photo by Mr. and Mrs. Cyril Jessop, Winnipeg.)

The hospital has accommodation for 700 beds. There is a large private service open to the patients of any reputable physician or surgeon in the community, and a public service under the care of the honorary attending staff, numbering thirty-two. The department for out-patients is very large, and an honorary staff of forty-five doctors minister to their ills.

THE TUBERCULOSIS CENTRAL REGISTRY AND CLINIC.

Up to the present the fight against tuberculosis in Manitoba—with the exception of King Edward Hospital, Winnipeg, for advanced cases, to which reference is made elsewhere—has been directed from the Manitoba Sanatorium at Ninette, 160 miles west of Winnipeg. In 1929 it was decided that since nearly half of the population of the province lies within a radius of ten miles of the Winnipeg City Hall, a Central Registry and Diagnostic Clinic should be established in the city. A brick building immediately to the east of the Winnipeg General Hospital

was put based, and is being remodelled. It will be connected by an underground passage with the General Hospital. When alterations are completed the structure will be used as a diagnostic clinic and a registry of all types of cases of tuberculosis and tuberculosis suspects in the province.

Misericordia Hospital.

Third in point of size among the hospitals of Winnipeg is Misericordia Hospital. It is under the direction of the Institute of the Sisters "de Misericorde," which was founded in Montreal on May 1st, 1845, and canonically approved on January 16th, 1848. The objects of the Institute are to help in the moral rehabilitation of the unfortunate victims of a deceitful world, and to rescue, nurse, and bring up the poor forlorn children. Its motto is "Misericordia derelictis." In 1893 a House of the Institute was established in Manitoba. Four sisters were brought out. Shortly after their arrival they bought land on Broadway, where they intended to lay the foundation of a permanent establishment. Unforeseen circumstances compelled them to abandon that site, and a new site was secured at the foot of Sherbrooke Street, close to Maryland Bridge over the Assiniboine. In 1900 the first part of the present structure was completed.

In 1907 the hospital was enlarged, and in 1912 the Asile Ritchot was built at St. Norbert to give shelter to 100 babies. In 1916 a training school for nurses was established, and the hospital, which at first had received only obstetrical cases, became a general hospital. In 1927 a large fireproof addition fronting on Wolseley Avenue was built. It contains splendidly equipped operating rooms and laboratories as well as wards, which bring the total capacity of the hospital to 225 beds.

The Children's Hospital.

In 1905 the idea of starting a hospital exclusively for children was brought before the Local Council of Women. A committee of four was chosen, with power to add to their number. It was decided to open a hospital for children in a locality where the death rate was highest, and, until the venture had shown its value, to solicit no funds, but to raise them by their own personal efforts and the efforts of their friends. By running a tea-shop, bazaars, literary teas, selling paper violets on the streets, and in other ways these women finally secured sufficient funds to enable them to rent a large house. On February 6th, 1909, the hospital was opened with one baby patient, one superintendent one maid-of-all-work, and a full staff of honorary physicians and surgeons. In that year 282 children were admitted and 546 new patients treated.

With the need of a hospital for the exclusive treatment of children established, a site of three and a half acres was procured on Aberdeen Avenue, overlooking the Red River. The present hospital was erected, and was opened for patients in November, 1911. It was formally opened in July, 1912, by H.R.H. the Duke of Connaught, and he and his consort became patrons of the hospital.

In 1916 a complete laundry unit was built, and in 1918 a nurses' residence. In 1925 the Shriners' Hospital for Crippled Children established a unit for the treatment of twenty patients by running one ward of the hospital. In 1928, by an addition, accommodation was provided for thirty-two. At the present time the hospital can accommodate 133 patients. The out-patient department is splendidly equipped with quartz lamps and other apparatus for phototherapy, supplied by the Kiwanis Service Club.

The Bureau of Child Hygiene.

Adjoining the Children's Hospital is the Milk Dispensary owned by the City of Winnipeg and under the direction of the Bureau of Child Hygiene, a division of the Health Department. In 1912, the year prior to the institution of the Bureau of Child Hygiene, the death rate of infants under 1 year was 207 per 1,000 live births. In 1928 the infant death rate was 63. The Bureau has three distinct services: the babies' clinic, milk dispensary, and visiting nurses. In the milk dispensary are prepared by trained dietitians the modified feedings prescribed by the clinic, the Children's Hospital, and private physicians. The clinic is open daily, except Sundays, from 9 a.m. to 5 p.m., for consultations, advice, and the weighing of babies. The nurses number fourteen—thirteen district nurses and one in attendance at the clinic.

Grace Hospital.

Grace Hospital was organized in 1904 by the Salvation Army in order to care for unfortunate girls and to provide accommodation for maternity patients. It was incorporated in the same year by special Act of the Manitoba Legislature, and for a time work was carried on in a rented house on Young Street. In 1905 the corner stone of the first section of the hospital at the corner of Preston and Arlington Streets was laid by the Hon. R. P. Roblin, Premier of the province. In 1911 the hospital was considerably enlarged, and in 1927 a fully modern building, of fireproof construction, four stories in height, and fronting on Arlington Street, was opened by Lady Willingdon, wife of the Governor-General of Canada. The three lower floors contain wards and nurseries, while on the fourth floor are waiting rooms, labour rooms, and operating rooms with the latest equipment. With this addition Grace Hospital now contains 149 beds for patients, and also accommodation for sixty girls, as rescue work among the unfortunate has always been part of the work of the Salvation Army.

Victoria Hospital.

Victoria Hospital, on River Avenue in Fort Rouge, was built in 1912 by the late Dr. Thomas Beath. A few years previously Dr. Beath had built and operated a hospital on Bannatyne Avenue near the Winnipeg General Hospital. This structure, a wood[illegible] building, was later used for a short time by the [illegible] Winnipeg as a hospital for infectious diseases.

Victoria Hospital is [illegible] stories in height, of reinforced concrete and brick [illegible]ction, and has accommodation for 103 adult patients [illegible]6 babies in the five floors used for hospital purposes. [illegible] nurses' home, a solid brick building, adjoins the [illegible], while across River Avenue is the Annex, a brick [illegible]ted building. This provides quarters for the [illegible] home and for hospital attendants. The hospital is [illegible]general, and accepts all cases which are not contagious [illegible]infectious. It is an "open" hospital in which any [illegible]-tered physician of good standing may attend his cases. Dr. Beath was managing director until 1919, when [illegible]resigned on account of ill health. The present direction of the hospital is vested in a board of directors, with Dr. J. P. Thomson as managing director.

St. Joseph's Hospital.

St. Joseph's Hospital, Winnipeg, conducted by the Sisters of St. Joseph, is situated on the corner of Salter Street and Pinkham Avenue, North Winnipeg; it was built in 1918, and operated as a private hospital until June, 1923, when it was taken over by the Sisters of St. Joseph of Toronto, and immediately converted into a general hospital of fifty beds; in September of the same year a training school for nurses was opened.

In January, 1927, a new unit containing operating rooms and private and ward accommodation was opened and a staff of attending doctors was formed for the departments of surgery, medicine, gynaecology, obstetrics, and eye, ear, nose, and throat. A radiologist and pathologist have since been appointed. In the same year an out-patient department was opened. The training school for nurses is under the direct supervision of the Sisters of St. Joseph, and is affiliated with the King George and King Edward Hospitals for communicable diseases.

The Order of the Sisters of St. Joseph was established at Le Puy, France, October 15th, 1650, by Mgr. Henri de Maupas, Bishop of Le Puy. In 1836 the first American foundation was made from the community at Lyons, France; and on October 7th, 1851, the first Canadian foundation was made at Toronto, Ontario. The special purpose of the Congregation of the Sisters of St. Joseph is the instruction and Christian education of youth, and the direction of charitable works, such as orphanages, hospitals, and homes for the poor and aged.

THE MUNICIPAL HOSPITALS.

The municipal hospitals, comprising King George Hospital for acute communicable diseases, King Edward Hospital for advanced pulmonary tuberculosis, the Small-pox Annex, nurses' home, power house, and superintendent's residence, are grouped in the south end of the city in a twenty-five-acre park, triangular in shape, with the Red River forming the base of the triangle. King George Hospital has 200 beds, King Edward Hospital 100 beds, and the Small-pox Annex 30 beds.

Hospital service as a civic utility dates back to January, 1911, when the old Beath Hospital, on Bannatyne Avenue near the General Hospital, was purchased to provide for the cases of scarlet fever prevalent at that time. Five months later a temporary building for cases of advanced pulmonary tuberculosis was opened. This building was located on the site in the Riverview district mentioned in the previous paragraph. In July, 1912, King Edward Memorial Hospital was ready for occupancy, and in February, 1914, King George Hospital was opened. H.R.H. the Duke of Connaught opened the King Edward Memorial Hospital and laid the foundation stone of the King George Hospital on July 11th, 1912.

Sixteen training schools in Manitoba, Saskatchewan, and Ontario send their student nurses to the municipal hospitals of Winnipeg for training in infectious diseases nursing. Medical students from the University of Manitoba also receive instruction here. The high standard reached by Winnipeg hospitals may be judged by the fact that all the hospitals come in the fully approved list of hospitals drawn up by the American College of Surgeons.

MOUNT CARMEL CLINIC.

The Mount Carmel Clinic is the most recent of Winnipeg's institutions for ministering to the sick. Located in a fine brick building on the west bank of the Red River at Selkirk Avenue, east of Main, it is well situated to serve the adjacent thickly settled district. The clinic is maintained by voluntary contributions, and renders aid to the sick poor without distinction of race, creed, or nationality. It contains the latest equipment for diagnosis and treatment.

WINNIPEG HEALTH DEPARTMENT.

Winnipeg has reason to be proud of its health department, which for a number of years has been under the direction of Dr. A. J. Douglas. As late as twenty-five years ago typhoid fever was prevalent and swelled the death rates. From 1904 onward energetic steps were taken to stamp out the disease, with the result that for the last ten years very few cases have developed within the city. The steps taken included an extensive campaign of education as to the means whereby the disease is transmitted, insistence upon sewer connexions, the abolition of outdoor privies, and the building of an aqueduct ninety-six and a half miles in length to bring a supply of purest water from Shoal Lake, an arm of the Lake of the Woods. The fight against other communicable diseases has been waged with equal vigour. Reference is made elsewhere to the municipal hospitals, which provide accommodation for sufferers from diphtheria, scarlet fever, tuberculosis, small-pox, and other communicable diseases. The Bureau of Child Hygiene, mentioned earlier, comes under the survey of the Health Department. The death rate for the City of Winnipeg for the year 1927 was 8.29 per 1,000 population, and not the least among the factors which keep the death rate at a low figure is the Health Department.

THE VICTORIAN ORDER OF NURSES.

The Winnipeg Branch of the Victorian Order of Nurses, an organization which extends across Canada, is particularly strong and efficient. It has existed in Winnipeg for twenty-nine years, and has grown with the community. The staff consists of a supervisor and twelve nurses. The Order also has a list of women who can act as helpers in the home when the mother is ill. The nursing service of the Victorian Order is divided into two classes—district and hourly. In district nursing the fees charged for visits are on a sliding scale according to the patients' ability to pay, though the size of the fee does not regulate the service. One of the objects of the Order is to foster a spirit of independence and self-respect among its patients. In hourly nursing a fixed rate per hour is charged. This service is run on a self-supporting basis, and is in no way a charity. In times past the Winnipeg Branch has also done industrial nursing—that is, assuming the nursing care of the employees of large departmental stores and other organizations. While at the present this work is not being carried on, the Winnipeg Branch is prepared to resume it when conditions warrant.

In connexion with the district work the Victorian Order carries on an educational campaign, through pre-natal and post-natal clinics, a "well baby" clinic at St. James's, and home nursing and mothercraft classes.

The Victorian Order Dental Clinic is a boon to those who cannot afford to pay the full charges of a dentist. Some fifty dentists of the city generously give their services free to this clinic.

The headquarters of the Winnipeg Branch are in the Medical Arts Building, itself a splendid monument of medical enterprise and co-operation.

THE MARGARET SCOTT NURSING MISSION.

This mission is called "The Margaret Scott Nursing Mission of Winnipeg," in acknowledgement of the unselfish and self-sacrificing labours of Mrs. Scott for many years in ministering to the physical and spiritual needs of the sick poor of this city. It is supported by a society formed to perpetuate the work of Mrs. Scott, who, happily, is still living, though in delicate health. The Mission was organized a little over twenty-five years ago. The nurses' home is at 99, George Street, in the east end of the city, close to the Red River. The Mission is undenominational and ministers to the sick poor without making any charge. In 1928 the visits made numbered 27,864, of which a great proportion were to female patients, as maternity nursing forms a large part of the work. The nurses are usually twelve in number, including six student nurses from the Winnipeg General Hospital and two student nurses from the Children's Hospital, who come to the Mission for two months' experience in district nursing.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

ANNUAL MEETING.

THE annual general meeting of the London and Counties Medical Protection Society was held at the society's offices, Victory House, Leicester Square, W.C., on April 30th, under the chairmanship of the president, Sir JOHN ROSE BRADFORD.

The annual report announced a substantial increase in membership: 805 new members were elected during the past year, 298 of whom were in the first year of their registration. The number of members on December 31st last was 11,856. During the year 1,079 applications for advice and assistance were received; in the majority of cases satisfactory results were obtained without litigation, and the issue of most of the cases in which litigation occurred was satisfactory. The report of the solicitors stated that there had been no spectacular litigation. In again issuing the warning that *x*-ray photographs should be taken in all cases of suspected dislocation or fracture, the solicitor added a further warning against placing reliance upon *x*-ray photographs taken by radiographers as distinct from the qualified radiologist; the medical practitioner might be running a grave risk in relying upon such photographs in the event of trouble arising.

Sir JOHN ROSE BRADFORD, from the chair, dwelt upon the financial strength of the society. The income had increased during the year by more than £600, and the expenditure was materially less than in the previous year. It had been possible to transfer the substantial balance of £4,562 to the accumulated funds. In total the assets of the society now reached a very large sum indeed, and its financial stability was thoroughly demonstrated. He paid a warm tribute to the members of the council and officers and staff for their excellent services.

The report and accounts were adopted, Sir John Rose Bradford was unanimously re-elected president, Dr. C. M. Fegen treasurer, and the vice-presidents and retiring members of the council were also re-elected, with four additions to the

list of vice-presidents—namely, Dr. R. L. Guthrie, Dr. C. O. Hawthorne, Dr. E. Farquhar Murray, and Mr. E. B. Turner—and two new members of council to fill vacancies—namely, Mr. H. W. Carson and Mr. H. Stubbs. Dr. Hugh Woods and Mr. A. G. R. Foulerton were re-elected general and financial secretaries respectively.

Dr. R. GUILBARD urged that there should be more young general practitioners on the council, and, especially with the increasing demands on the insurance practitioner in relation to the Ministry and to the bodies charged with insurance administration, that more men or women engaged in insurance practice should be included.

Dr. C. M. FLUX, chairman of the council, replied that every effort was made to ensure that the council was representative of every branch of medical practice. Three out of the twelve elected members were insurance practitioners, and certainly three of the vice-presidents had had considerable experience in that field, and in one case this was continuing. The council had to deal with many cases in which insurance practice was concerned, and was well aware of the pitfalls which beset the practitioner. Where the practitioner had been in conflict with the law in the society had very often been of great assistance in maintaining his rights. As for an accession of young practitioners to the council, it was with a view to making it possible for them to serve—men to whom the time involved in such frequent attendance was an important consideration from the financial point of view—that the society some years ago decided to remunerate the members of the council to the extent of one guinea for each of the fortnightly or weekly attendances.

The meeting concluded with two votes of thanks, one, proposed by Dr. FLUX, to the solicitors of the society, Messrs. *Le Brasseur and Oakley, for their skilled and unstinted help* in many difficult and contentious cases, and the other, proposed by Dr. OWEN FOWLER, to Sir John Rose Bradford, for his advice and assistance on the many occasions on which it was sought and for the prestige which his name and authority gave to the society.

Scotland.

Department of Health for Scotland.

THE first annual report of the Department of Health for Scotland, which succeeded the Scottish Board of Health on January 1st, 1929, has just appeared.[1] This report of 230 pages, to which further references will be made in later issues, is divided into twelve chapters dealing with the following subjects: housing and town-planning, slum clearance, *general sanitation, food supply, maternity* service and child welfare, school health administration, infectious diseases, Highlands and Islands medical service, national health insurance, *pensions*, Poor Law, welfare of the blind, and miscellaneous. The salient event of the year was the passing of the Local Government (Scotland) Act, 1929, effecting many important changes in the finance and organization of Scottish local government. In preparation for these changes, which take place on May 16th next, much preliminary work has been done in the Department, and a series of circulars have been issued for the guidance of the new authorities dealing broadly with policy in the health services and the Poor Law.

Work of the Blind in Scotland.

On April 28th the Secretary of State for Scotland opened a recent extension of the workshops of the Aberdeen Asylum for the Blind. These had been erected at a cost of between £4,000 and £5,000. Mr. Adamson said that this institution had been founded 112 years ago when Miss Christina Cruik-bank left the sum of £8,000 for the benefit of the indigent blind in the counties of Aberdeen, Kincardine, and Banff. In 1890 special provision was made by the State for the education of blind and deaf children aged 5 to 16; in 1918 the age was raised to 18. This was the charter of the blind child, as the Blind Persons Act of 1920 had been the charter of the blind adult, providing the old age pension at 50 instead of at 70, and making local authorities responsible for the welfare of blind persons. For forty years blind children had been receiving a good education, and many of them had made excellent use of their opportunities. In the last ten years institutional accommodation for blind persons in Scotland had increased by over 50 per cent.; in that period the State had made grants in Scotland amounting to £165,000. Including what had been spent on old age pensions and by local authorities, blind persons had received a total of £1,055,000 between 1920 and 1928. The blind to-day were therefore better cared for in every way. In 1929 there were 8,500 persons on the central register of the blind. An encouraging fact was that in the last nine years the number of blind children of school age had *fallen from 339 to 285*; it was still more encouraging that the number of those under 5 had fallen from 38 to 11. This might be regarded as a triumph of preventive medicine; it was worthy of note that at the present time there was not a single blind child *in the county or city of Aberdeen* or in the counties of Banff and Kincardine. Most of the credit was due to those who were concerned with maternity and child welfare. The question of training and employment of the blind was perplexing; there were three difficulties: employment after training, the need for new industry, and the disposal of goods. Mr. Adamson thought that the co-operation between the managers of the four institutions for the blind in Scotland showed promise of *fruitful results*.

Edinburgh School for Mentally Defective Children.

The new St. Nicholas School in Gorgie Road, Edinburgh, erected by the Edinburgh Education Authority to accommodate a hundred mentally defective children, was opened on April 30th by Mr. W. W. M'Keehnie, secretary of the Scottish Education Department, under the presidency of Councillor P. H. Allan, chairman of the Education Authority. Mr. M'Keehnie said that this was an open-air school of a kind hitherto unknown in Scotland. At the present moment there were 5,400 physically defective and 3,600 mentally defective children in Scottish schools. The number of these young patients had doubled in the last fifteen years, simply because the local authorities had become more aware of the extent of this problem, thanks to the development of the school medical service. Edinburgh had made an important contribution to this work, for at the present moment it was dealing with over 1,000 such children in about twenty centres. The work of the education authorities was the basis of future provision, and the foundation of preventive work for defectives. The school occupies an area of about two and a half acres; it is a one-story building, planned round an inside courtyard. The sides of the classrooms have glass doors which can be adjusted so that they open on wide verandahs; ventilation is a special feature. There are five classrooms, each accommodating twenty pupils, in addition to a manual instruction room, cookery room, dining hall, and medical inspection room. The total cost, excluding cost of the site, was over £12,000.

Edinburgh Foot Clinic.

At the annual meeting of the Edinburgh Foot Clinic Mr. C. W. Cathcart, F.R.C.S., who took the chair, referred to the work that had been done since the clinic came into existence in 1924. The report showed that the number of treatments during the year amounted to 8,515, compared with 7,819 in the preceding year. There was a waiting list at the end of the year of 1,791 names, and patients had to wait some three months before they received attention. This period, the committee hopes, will be reduced as soon as funds permit an increase in the number of operators. It is pointed out that although the operators give their services free, the annual expenditure exceeded the income for the year by £36. The chairman mentioned that chiropody as a minor surgical specialty had made great progress both in preventive and in remedial treatment. It was stated by Councillor Mrs. Morison Millar that an attempt was being made to include chiropody in the services rendered under national health insurance.

Edinburgh Deaconess Hospital.

At the thirty-fifth annual meeting of the Church of Scotland Deaconess Hospital, Lord Sands, chairman of the Board of Management, in presenting the annual report, referred to the recent death of Dr. J. W. L. Spence, who was radiologist to the hospital for many years. During the year 750 in-patients and 6,703 out-patients were treated. The ordinary income was £6,955, and the ordinary expenditure £5,618. Dr. Haig Ferguson, president of the Royal College of Surgeons, said that the hospital was doing admirable work in training nurses for the mission field.

England and Wales.

The Tavistock Square Clinic.

THE annual meeting and luncheon of the Tavistock Square Clinic for functional nervous disorders took place on May 5th under the chairmanship of Dr. H. B. Brackenbury, Chairman of Council. At the business meeting a report was presented evidencing increasing work under conditions of very great pressure. The number of new cases attending the clinic during the year was 625, a large increase on previous figures, and the total number of cases which had been under treatment during the twelve months was over 900. The medical staff now numbers 40, of whom 21 are full physicians of the clinic, and 14 clinical assistants. Progress was reported with regard to an extension scheme comprising an Institute of Medical Psychology, which would be a demonstration and research unit to further the prevention and early treatment of nervous breakdown; this scheme was expounded in the *British Medical Journal* of October 26th last (p. 774).

More than 300 sat down at the luncheon, when addresses were delivered by Dr. W. J. Adie (in the absence of Sir E. Farquhar Buzzard), Miss Ishbel MacDonald, daughter of the Prime Minister, and Dr. H. Crichton Miller, honorary director of the clinic. Dr. Brackenbury mentioned that Dr. J. R. Rees, the deputy director, was at Washington, attending the International Congress of Mental Hygiene, which was being opened that day by President Hoover, and a message of greeting and good wishes was cabled to the congress from the meeting. Dr. Adie said that he welcomed the opportunity of telling a lay audience what he and many of his colleagues thought of the present lack of adequate facilities for treating patients suffering from functional diseases of the nervous system, the need for institutions where physicians trained in special methods could treat their patients in a suitable environment, and the excellent work which the Tavistock Square Clinic was doing in that connexion. Again and again he had been forced to tell hospital patients suffering from functional nervous disorder that he was unable to provide them with the treatment they needed, and that he did not know where they could obtain it. Things were now a little better, because he could send them to Tavistock Square, but the clinic could not accommodate them all. Many patients suffering from a functional condition were convinced that some form of physical treatment would cure them, with the result that bizarre and magical methods were supplied and resorted to, while, on the other hand, patients whose symptoms were due to physical disease might say that they knew it was all "nerves," ask for treatment by mental suggestion or analysis, and fall into the hands of some ardent but ignorant psycho-therapeutist for a long course of unnecessary and perhaps harmful mental treatment. It was because he knew that these errors were carefully guarded against at the Tavistock Square Clinic, and that psycho-therapeutic treatment was not indiscriminately given, that he and his colleagues recommended the institution with great confidence. Miss Ishbel MacDonald, in an admirable little speech, referred to the preventive aspect alike of modern medical treatment and of social legislation. The clinic, she said, was doing valuable work in readjusting to society those who, somehow, had got into the wrong groove. She wished there were more such clinics where sympathetic understanding and treatment were available, and that they were supported by homes where during their period of restoration patients might be kept away from their ordinary surroundings, which were often unfavourable.

Dr. Crichton Miller, in some account of the year's work, expressed a welcome to Dr. Brackenbury in the chair. A year ago Dr. Bedford Pierce, soon after he had accepted the position of chairman of the clinic, was made a member of the Board of Control, and felt himself obliged to resign the chairmanship. Dr. Brackenbury brought to the chairmanship the prestige of many years' notable work for the British Medical Association, and his name was one to conjure with in the medical profession all over the country. It was one of the most flattering things that had ever happened to the clinic, said Dr. Crichton Miller, that Dr. Brackenbury should have accepted the chairmanship. The year's work at the clinic might be described as "growth without expansion." Two years ago the number of attendances for treatment was 4,000; during the last twelve months it was 7,500, and the waiting list was a sore difficulty. What was wanted was not so much extension of the clinic as multiplication of it, but the present lack of space meant that it was impossible to take on more staff and consequently impossible to train more doctors. He added that an increasing number of cases came from two interesting sources. One of these was the hospitals, which sent many cases of neurosis, and the other was the courts. Mr. Clarke Hall and other metropolitan magistrates sent to the clinic a large number of child or adolescent offenders, and in dealing with them the clinic felt that it was fulfilling a very important function.

Small-pox and London Council Schools.

A regulation of the London County Council provides, *inter alia*, that children who reside in a house in which any person is suffering from infectious disease shall be excluded from school for any period which may be prescribed. This part of the regulation, however, is to be suspended. In the areas in which small-pox is most prevalent the problem of supervising contacts is becoming a matter of some difficulty, and after consultation with the Ministry of Health and the medical officers concerned, it is considered advisable, in order to facilitate the task of supervision and to prevent spread of the disease, that children in whose homes small-pox occurs should be allowed to attend school under daily observation by the school medical service whilst the children remain in good health. It is believed that, by keeping the children under daily observation in school, disease can be detected in its early stages, whilst contacts who absent themselves from school during the period of observation can be reported at once to the borough medical officer, who is thus kept informed of cases which may possibly be developing small-pox. In schools which are not under special observation these measures are not possible, and it has sometimes happened that children suffering from a mild attack of small-pox have attended school while the rash has been out for some days. The new procedure has been designed to prevent as far as possible such cases being overlooked, and will only apply in the case of the present very mild type of small-pox. During the first ten weeks of the present year 1,528 cases of small-pox were notified and confirmed, of which 491 were in children attending council schools. No vaccinated school child developed small-pox, and generally the children reported were suffering from a mild type of the disease. The recommendation agreed to by the Council on the proposal of the Education Committee was that the operation of the regulation

> "so far as it relates to the exclusion from school of children or pupils residing in a house in which any person is suffering from any infectious disease, be suspended, in order that, in those schools which can be kept under daily observation by the school medical service and where the borough medical officer of health concurs, children living in houses from which cases of small-pox have been removed may be permitted to attend school, whilst in good health, subject to the discretion of the school medical officer."

Presentation to Dr. A. Brown Ritchie.

Dr. A. Brown Ritchie, the first medical officer appointed by the Manchester Education Committee, retired on April 23rd, after serving for nearly twenty-seven years. Before his appointment he had been engaged in general practice in Manchester and had been secretary of the Manchester Division of the British Medical Association, and was actively concerned in the arrangements for the Annual Meeting in Manchester in 1902. On April 15th, Dr. Ritchie was the recipient of a presentation from the members of his staff. Dr. H. Herd, senior assistant in the department, expressing regret at Dr. Ritchie's retirement, emphasized the fact that he had never forgotten to deal with those under his orders as members of one professional brotherhood. His essential kindness of disposition had endeared him to all with whom he came into touch. Mr. E. D. Telford, surgeon to the residential cripples school, testified to Dr. Ritchie's tact as an administrator and to his readiness to allow the special research work of his assistants to be published under their own names in his reports. Dr. Ritchie has also received presentations from

the combined staffs of the education office, and from the teachers in the special schools for physically and mentally defective children. It may be recalled that his appointment to the post of school medical officer was made a few years before the official institution of school medical inspection, and at a time when few of even the more progressive local authorities had begun to realize the necessity for this kind of work. After the passage of the Act authorizing normal medical inspection Dr. Ritchie was enabled to conduct a more systematic scheme, and since 1907 further development has been rapid. The first staff in 1909, which comprised four full-time assistants and five nurses, has been increased to nineteen full-time assistant medical officers, four full-time specialists, eight full-time dentists, sixty-two nurses, and five masseuses. The first clinic was opened in 1915, and there are now nine in full working order. Manchester also possesses five residential schools for cripples, pre-tuberculous or other delicate children, and also one for epileptic children, which is unique in this country; the medical control of all of these has been in Dr. Ritchie's hands.

Royal Sanitary Institute.

The annual congress of the Royal Sanitary Institute will be held this year at Margate, under the presidency of Lord Cornwallis, from June 21st to 28th. A large number of representatives of the American Public Health Association are expected to take part in the proceedings. Sir Andrew Balfour will preside over the section of preventive medicine, Sir Thomas Neill over that of the National Health Insurance Services, and Lady Howard de Walden over the section of maternity and child welfare and school hygiene. Among the subjects to be discussed are: psittacosis; maternal mortality; health authorities and midwifery; the county district medical officer and the Local Government Act, 1929; food in relation to dental hygiene; slum clearance and housing; and midwifery and health visiting in rural areas. The congress lecture will be delivered by Dr. O. Charnock Bradley, principal of the Royal (Dick) Veterinary College, Edinburgh, who will speak on diseases of domestic animals from the human angle. Further information may be obtained from the secretary of the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.1.

Correspondence.

AMPUTATIONS AND ARTIFICIAL LIMBS.

SIR,—The condemnation of the late results of Syme's amputation of the leg by some of the speakers in the discussion on amputations in their relation to artificial limbs in the Section of Surgery of the Royal Society of Medicine (reported in your issue of April 12th, p. 693) came as somewhat of a shock to me, for I have long considered the amputation as one of the best in surgery from a practical point of view. I feel, however, that there is no gainsaying the deliberately expressed opinion of a surgeon who has had so much experience of war pensioners as Dr. Langdale-Kelham, who speaks with no uncertainty of the supervention of stump troubles after the lapse of ten years. It may be presumed that he was referring to cases seen at Roehampton, in which amputation had been performed for war injuries, such as frost-bite gangrene or severe sepsis. It has occurred to me that an inquiry into the remote results of Syme's amputation in civil practice would be interesting, and might possibly reverse the verdict pronounced on these stumps in the hospitals of the Ministry of Pensions.

The artificial limb makers seemed to me to be likely to have information in their possession which might affect the decision, and I therefore wrote to some of the London firms of longest standing and experience, asking them to tell me if their experience in civil life supported the condemnation of the Syme stump after the lapse of ten or more years from the date of amputation. I received answers to my inquiries from some of the best known and longest established artificial limb makers, and in no case do these answers support the condemnation of the Syme stump. One of the firms has put the case so clearly that with your permission I will quote its letters. The first reads as follows:

"We have to state that all the members of our staff are unanimous that they have no recollection of troubles such as you mention with regard to amputation through or just above the condyles of the femur or Syme's. We cannot recollect a single instance of this nature. We have noticed a rather excessive shrinkage of these stumps, but this had no bad effect from the limb-maker's point of view."

In reply to a further inquiry the same firm wrote:

"In reply to your letter we confirm that the remarks made in our last letter to you apply to civilian cases only, and not to war pensioners. We have quite a number of customers who have been wearing artificial feet for Syme's amputations for 19 years or more, some for 29, 30, and even 40 years, and although from the aesthetic point of view we do not like the amputation, as it is very difficult to conceal the fact that a limb has been lost, especially in the case of a lady, we are bound to state that, considered as an amputation only, it is in our experience an entirely successful one, and, as we have already stated, we have no recollection of any stump trouble such as you mention."

There would seem to be two sides to the shield, which are very different. The speakers at the Royal Society of Medicine have confined their attention perhaps to the military side. My limb-making correspondents speak only of the civil. Each is probably giving a correct account of his own side.

In frost-bite gangrene and in the cases of severe sepsis which were too plentiful in the late war, surgeons, with the laudable desire of saving all they could, often amputated only a little above the line of demarcation or the obviously infected tissues. Although many such stumps healed apparently soundly, they did not consist of normal tissues, but of badly nourished and badly innervated bones and soft parts, and the late results have been such as Dr. Langdale-Kelham and others referred to in the discussion.

I venture to think that it would be little short of a calamity if civil surgeons were to be guided exclusively by military experience, and if such a useful proceeding as Syme's should be abandoned in favour of a higher amputation. A good Syme is about the only stump upon which a patient can jump "barefoot." I have seen one such, who had lost both feet, jump from a chair on to the floor "barefoot," obviously without any inconvenience. I would also put in a plea, but with less fervour, on behalf of Carden's amputation of the thigh in non-septic cases; for the longer the stump the better the control of the artificial knee-joint.—I am, etc.,

London, S.W., May 1st. E. MUIRHEAD LITTLE.

GLANDULAR FEVER.

SIR,—The unusual number of cases of glandular fever which I have seen personally in the course of the last few weeks suggests that an extensive epidemic is in existence.

In children, the features have agreed with the usual characteristics. There are one or two days of malaise followed by rapid and marked enlargement of the cervical glands. Other glands may or may not be enlarged. In the fauces there is usually some reddening and the tonsils may be definitely enlarged, but signs of sepsis or exudation are slight or entirely absent, except in patients with previous tonsillitis. The cervical glands may be uncomfortable, but their size is out of proportion to the degree of tenderness or to the general symptoms. Lymphocytosis has been present in most cases, the total number of leucocytes and the percentage of lymphocytes both being increased. I have not seen a case with haematuria this year.

In adults the swelling of the glands has been less marked, as is usual. They may be quite painless and thus be completely overlooked. Moderate lymphocytosis has been present. The pyrexia may persist for several weeks, long after all constitutional symptoms have subsided.

Occasionally the blood shows a polynuclear leucocytosis. The glands in these cases are usually more tender, and after persisting for two or three weeks they may suppurate. I do not think that I have ever seen suppuration occur in a case with lymphocytosis at the onset.

The main trouble in glandular fever is the long period

of depressed health which not uncommonly follows the acute attack. For six months or more subsequently the patient is often "below par," and may be somewhat anaemic. The glands may remain palpable for several months, but finally disappear entirely.

There are many doubtful points in regard to glandular fever. The incubation period is usually between five and twelve days, but possibly may be longer; evidence is not sufficiently extensive. The duration of infectivity is even more uncertain; provisionally it may be said to last until (1) the temperature has been normal for one week; (2) the greater part of the glandular swelling has subsided and there is no tenderness; and (3) the fauces are clear. The degree of infectivity is not high. I have never seen an obvious case of infection in a hospital ward. If one child in a family is affected it is unusual, though by no means unknown, for the other children to catch it. On the other hand, susceptibility to mass infection is very high. If two or three cases occur in a school, probably nearly all the other children will have it in various degrees of severity, mostly mild. Many points with regard to the lymphocytosis are also uncertain. Sporadic cases usually exhibit this to a greater degree than occurs in epidemics in schools and institutions. There is no characteristic eruption; indeed, rashes of any type are rare, though various macular and erythematous eruptions are seen occasionally.

In addition to these cases of glandular fever, I have recently seen several cases of "unexplained pyrexia" in adults with no glandular enlargement and no lymphocytosis. There is certainly no evidence to connect these with glandular fever. They are not enteric nor, one may add, psittacosis. They differ from "influenza" in the fact that the temperature is out of proportion to the constitutional symptoms, which are slight and transient. The pyrexia may persist for several weeks, finally settling without complications. It may be by chance that I have seen several cases of this latter type within a short period, but of the existence of an epidemic of glandular fever I feel little doubt.—I am, etc.,

London, W.1, May 5th. H. LETHEBY TIDY.

PSITTACOSIS.

SIR,—In an editorial on psittacosis in the *Journal* of May 3rd (p. 831) it is stated that:

"... Nocard's bacillus (*B. psittacosis*), and other bacteria which were formerly suspected, being regarded as not concerned in their usual form, though it is agreed that the filterable virus is very closely connected with the group of the typhoid and salmonella organisms. This conception helps to explain the partial resemblance of the clinical symptoms to those of enteric fever, and the incipient agglutination of the blood of some psittacosis cases to bacilli of the typhoid group."

The conception in question, which is the purely personal view of Dr. Roubakine, is entirely unsupported by evidence, and seems to us unnecessary. Our investigations have shown that this disease is due to a filterable virus, and that neither the bacillus of Nocard nor any other of the salmonella group plays any part whatever in its etiology. Incidentally the idea that this disease was due to a filterable virus did not, as your article would suggest, come from the clinical side, but was the outcome of laboratory work. These observations have received ample confirmation both in America (Krumwiede, McGrath and Ollenbusch) and in Germany (Levinthal, Elkeles, Pesch). Nocard's hypothesis was based on such flimsy evidence that it scarcely needed refuting. Only once in the history of this disease has *B. aertrycke* (*B. psittacosis*) been isolated from a human case, and the fleeting and low-titre agglutinations for different members of the typhoid and salmonella groups occasionally met with were never taken seriously by competent bacteriologists. We are at a loss also to understand why a typhoid state necessarily implies infection with *B. typhosus* or one of its near relatives. Surely the typhoid state is met with in a number of diseases—influenza, typhus fever, uraemia—and no one thinks of making a member of the typhoid group responsible for the clinical picture in these cases. We recognize, of course, that Dr. Roubakine is entitled to evolve any hypothesis that he cares to, but we feel that it is unfortunate that a journal of the standing of the *British Medical Journal* should give support to such a flight of the imagination by incorporating it, without a single word of criticism, in an editorial article.—We are, etc.,

S. P. BEDSON.
London Hospital, May 5th. G. T. WESTERN.

UNSUSPECTED TRICHINOSIS.

SIR,—Eight cases of trichinosis have occurred within the last ten days in the cooked meat department of a bacon factory in this town. The first case to be diagnosed was that of a youth who called at his panel doctor's surgery on his way home from work, with a swollen face, marked oedema of the lids, headache, and pains in the limbs; his temperature was 102°, but the urine contained no albumin. He stated that there were three or four more workers in his department similarly affected. The doctor was struck by the similarity of the symptoms to those of a case reported in the *Journal* of April 5th (p. 650), and by the fact that he was a worker in a bacon factory, and reported the case immediately to the public health authorities.

An investigation into the series of cases is being carried out, and has entirely confirmed the first diagnosis. Two patients gave a history of sickness before the appearance of oedema, and one of definite abdominal pain. All have had a marked eosinophilia of from 75 to 22 per cent. Active trichinae have been seen in the stools of two cases admitted to hospital, who also show temperatures with an evening rise to 103.4° and a morning fall to 99 to 100°, with more abdominal pain and intense, widespread pain and tenderness of voluntary muscles. All but one of the patients have owned to the "tasting" (to a greater or lesser degree) of a certain preparation which has been made only for three to four weeks, which contains—prior to the final scaling of tins and sterilization in a high-powered steam retort—a certain proportion of uncooked sow-meat.

The investigation is still continuing, but the practitioners and authorities concerned feel that the presence of this outbreak should be made known in view of the possibility of trichinosis showing itself in other areas.—I am, etc.,

Bradford-on-Avon, May 5th. JEAN MURRAY.

STERILITY IN WOMAN.

SIR,—I am obliged to Dr. Leith Murray for his discussion of some of the points in my address. I suppose nothing ever written, or likely to be written, on this subject will do otherwise than lend itself to discussion. I am glad, therefore, to find that we are in agreement on certain matters. In respect of those in dispute, I venture to think the explanation of the differences of opinion is not difficult.

Dr. Leith Murray lays stress on anteflexion of the cervix—a condition which is identical with what is often called cochleate uterus—as a cause of sterility. This lesion was not mentioned specifically by me, but was included in the general statement about many congenital lesions being amenable to surgical intervention. I did not intend it to be considered among the conical and hypertrophied cervices. As indicated in my address, I had not space to go into all these matters in detail. I agree with Dr. Leith Murray that this is a cause of sterility which is fairly common. In many cases, however, it is not only the cervix which is at fault, but also the uterus and genitalia which may be underdeveloped. For many years, whenever I have performed anterior hysterotomy, as I usually do for the relief of the dysmenorrhoea often associated with this condition, I have also, if the uterus be not too underdeveloped, performed posterior cervical section in order to make pregnancy more probable, and I do this even though the patient be unmarried, in case she should subsequently find a husband.

I cannot enter here into a discussion as to the value of Hodge's pessaries. Let it suffice for me to say that no one has taught more assiduously than I have done the importance of the position of the uterus being rectified, and of a Hodge pessary being inserted, in all cases in which a *nulliparous* woman complains of symptoms which may be attributable to the position of the uterus, to test whether

this is so or not before any question of operation is considered. For the reasons briefly indicated in my address—and there are other strong and obvious reasons—where it appears that pregnancy is being prevented by the position of the uterus, I prefer operation.

Now, with regard to the frequency of infection as a cause of sterility, I stated, with statistical reservations, that this may be estimated to be about 40 per cent. of all cases. This is probably a conservative figure when all sterile patients, with and without obvious pelvic lesions, are taken into account. Many observers place it much higher—Semlukoff (1926), indeed, found in a series of patients that there was impermeability of the tubes in 65 per cent.; and a reviewer of his paper states that this figure "agrees roughly with that of other observers." Again, I must draw attention to the possibility of statistical fallacies in small groups of patients, and to the variants that might occur in different districts—seaports, country, and so on. The figure—40 per cent.—that I have mentioned is, however, very little higher than the number of occlusions noted (35 per cent.) in our series of 62 cases without definitely observable lesions at the Royal Infirmary. These results were kindly collected for me by my registrar, and they accord, as already stated, with the findings of other workers.

Dr. Leith Murray's statement that he has observed tubal patency (positive test) in 95 per cent. of what he believes to be a series of cases similar to my own is undoubtedly interesting, for no one else has, so far as I know, reported so high a figure; mine, as already mentioned, is 65 per cent. But Dr. Leith Murray does not tell us whether a radiograph was taken to prove the passage of air in all of his cases. I have reason to believe that this precaution was not observed. All my patients were so tested. This is one of several reasons why I do not attach much importance to Dr. Leith Murray's figures. He adds: "I must emphasize that the apparatus I use (Victor Bonney's) is tested before each procedure"; but in what way he does not state. I, too, emphasized this point, for there are many junctions that may leak, and I described how it was done—a matter of some moment. In passing, I may remark that Mr. Bonney's apparatus is identical with the one which I always employed long before his method was described, and I am under the impression that I mentioned this after the publication of his account. I believe that I was the first in this country to practise the principles of Rubin's method, which I saw in America in 1921; but I am afraid I considered my apparatus too simple and obvious to warrant description in the medical press.

Dr. Leith Murray writes a good deal about the question of the pressure that may be employed. I merely stated that the air usually passed through patent tubes at about 80 mm. of mercury, and that it was not advisable to go beyond a pressure of 200 mm. of mercury lest rupture occur. Further, if the air does not go through at a pressure of 200 mm. of mercury, or even at a little less, the tubes are almost certainly abnormal, although we believe that we have encountered spasm of the musculature which temporarily prevented the air from passing. In these circumstances it is wise to repeat the test if there is any doubt, as I think I made clear.

I am sorry that Dr. Leith Murray should impugn our technique, for in doing so he implies that he alone of all those who have practised the method is capable of accuracy, since his figures, I believe, are unique. It is, therefore, incumbent on me to show that this is not necessarily so. I have already indicated that the omission of radiography may have led him into a false position; but there is something more which should have been quite obvious to anybody who had studied my address—namely, that since our negative cases—that is to say, those in which tubal occlusion was demonstrated by inflation and radiography—were submitted to operation, we had further proof of the accuracy of our findings, and this did not apply, I take it, to Dr. Leith Murray's so-called positive results. Our findings, then, were proved by radiography and operation; his findings by some subjective method not disclosed. I have often said to my assistants during these operations, "It is very interesting how accurate our tests have proved to be." I have on one occasion only operated upon a patient in the circumstances recorded when a negative result had been reported and found the tubes patent. In this case one test only had been made by a new house-surgeon. Practically all the cases recorded in my address were inflated by a house-surgeon or registrar. I think that great credit attaches to them for their proven accuracy.

There is another point in regard to Dr. Leith Murray's figure of 95 per cent. of positive results, and it is this: when I spoke of the absence of physical signs and symptoms I referred only to the pelvis, as the context shows, because a large number of patients suffering with sterility are the subjects of what I may call "hormonic insufficiency." Such cases should be treated on their merits, and not necessarily be inflated, for the tubes would nearly always be patent. This is not, of course, to say that a woman with thyroid insufficiency may not have tubal occlusion, but still the point is that many cases are inflated in which the woman is suffering from a constitutional disturbance, and these naturally should not be regarded as positive results so much as diagnostic errors. It may be said, then, that the percentage of positive results (patent tubes) will be in inverse ratio to the differential diagnostic ability of those concerned, especially when the husbands are not taken into account. From this point of view my percentage of occluded tubes (35 per cent.) is lower than I could wish. Still, in some cases in which sterility is due to constitutional disturbances, inflation must be practised to exclude coincidental tubal occlusion.

Lastly, Dr. Leith Murray discusses the very important procedure of the examination of the husband, concerning the possibility and wisdom of which he is not an advocate. If he had questioned any of my registrars or house-surgeons during the last few years, when inflation has been practised at the Royal Infirmary, he would have learned that in a considerable proportion it has been found possible to examine the semen of the husband. A matter of this sort depends, of course, largely on the degree of co-operation between the surgeon and his staff. It is nearly always possible in private practice. I frankly disagree with Dr. Leith Murray that a woman should be subjected to the unpleasant procedure of inflation without the husband being examined, if at all possible. Moreover, he does not seem to recognize the fact that failure to do so depreciates his positive-test percentage to the extent of 20 per cent. Women have enough to bear in regard to procreation without being penalized in respect of sterility, for, as Schwarz (1925) concisely states, the position in regard to female sterility is that the husband is directly, or indirectly by infecting his wife, responsible for about two-thirds of all cases. As to the possibility of untoward events in regard to husbands of mental instability, much might be said; but for practical purposes I would regard such occurrences as being largely due to want of perspicacity on the part of the surgeon in not recognizing the type of man with whom he had to deal. It is always possible to avoid domestic disharmonies and stripping a man of his masculinity. Besides, we know that in the male, as in the female, infertility may be temporary, and great use can be made of this knowledge if it be properly applied.

I regret the length of this letter prevents my referring to other points of interest which have not been mentioned. —I am, etc.,

Liverpool, April 29th. W. BLAIR BELL.

THE TEACHING OF ANATOMY.

SIR,—The Arris and Gale Lecture by Mr. McAdam Eccles published in the *Journal* of March 1st (p. 373) is interesting; one feels thankful that the facts therein dealt with have been brought to the notice of the profession by a teacher of such eminence. May I be permitted to offer the following observations on some of Mr. Eccles's remarks?

Some thirty years ago it was my good fortune to have been introduced to the study of human anatomy by Dr. R. J. A. Berry, then lecturer on anatomy in the New School of Medicine in Edinburgh, and subsequently professor of anatomy in the University of Melbourne. I can hear him telling us that the term "internal abdominal ring" was a very good one, except for the following facts: (1) it was not internal; (2) it was not abdominal; (3) it was

not a ring. I can see him showing us the small dimple in the peritoneum lateral to the deep epigastric artery, explaining to us what point of the fascia transversalis lies immediately in front of it and what had happened at that point, and what was the meaning of that dimple. He used almost the identical words of Mr. McAdam Eccles in expounding to us what happened in Pott's fracture, and told us time and again that human anatomy concerns the living and not the dead. I can hear him emphasizing precisely the same points in connexion with the lateral movements of the ankle-joint.

Out in these parts my students sometimes take umbrage when they come to me with some statement in some book or other and ask me about it, because at such times it is my habit to tell them that I am not in the least concerned with such matters, and that the best thing for them to do is to refer to the "book" lying on the dissection table. Again, they sometimes get wearied at my insistence that it is a matter of great misfortune that we cannot dissect the living body, but I try to relieve the monotony of such a remark by pointing out how greatly blessed they would be if only we could dissect alive one of my colleagues, believed by them to be a very severe examiner, but in actuality one of the best fellows alive. Moreover, they sometimes get wearied by my repetition of the many changes in abdominal relationships from that given in books if the stomach happens to be distended; in this country the surgeon is fairly often called upon to deal with abdominal injuries in people with stomachs distended by a meal topped with large draughts of the local small beer.

The really cogent criticism made by Mr. McAdam Eccles is the divorce of the anatomist from the clinical application of his work. It is not always the case that he gets ready help from the clinician and from the radiologist. For seven years now I have been trying to get radiograms of fractures of the clavicle, of the humerus, and of the femur to enable me to help my students to understand what is happening and why it is happening. For seven years I have been trying to get my students to understand the meaning of the great omentum and of the enteric mesentery and of the transverse mesocolon. I have not received a single radiogram, and there never has been a single opportunity of showing the students the limitation of some inflammatory process to some particular region of the abdomen. It is greatly to be hoped that the protest of Mr. Eccles may do something to help us to a happy issue out of at any rate one of our afflictions.—I am, etc.,

HODGKINSON LACK,
March 27th. Department of Anatomy, University College, Rangoon.

INSTITUTIONS TRANSFERRED UNDER LOCAL GOVERNMENT ACT.

SIR,—One of the promises of the Local Government Act, 1929, was the disappearance of the Poor Law and of the type of service and institution which the mind and experience of the public associated with the Poor Law. Clause 5 of the Act was drawn with the particular design of promoting this disappearance. It permitted councils to declare that as soon as possible all assistance which could be given otherwise than as poor relief would be so given. The Council of the British Medical Association gave strong support to this clause, its intention being the same as that of the Minister—to do everything that could be done to release the service given from the so-called taint of the Poor Law.

There is a definite danger that proceedings taken under this clause will have an effect directly opposite to that desired by the Association. Either under the clause or by appropriation, councils are declaring that they will administer *some* of the transferred institutions under the Public Health Act, 1875, and are placing these *selected* institutions under the Public Health Committee or some such existing committee, leaving a remainder of the transferred institutions under the administration of the Public Assistance Committee.

There are thus being set up two types of institution in each area, one of which will be called public hospitals, the other will be poor relief institutions, and the two types will be under separate administration. I believe this is not to be so in London, but in the counties and county boroughs it will be the usual result of action taken under Clause 5. We shall thus have with us institutions of the old Poor Law type, but still more definitely set apart from the public hospital class than was the case under the Poor Law. We shall see much of the work of the guardians in raising the status of their institutions undone, and the result will be the exact opposite to that at which the Act aims and the public desires.

Nothing seems to be more clear than that *all* the transferred institutions should be under one control and organized into one service. All the transferred institutions are institutions for the sick. This is the crucial point of the matter. Anyone who cares may assure himself on this point. Let him go into one of the institutions to-day and ask to see an able-bodied pauper; he will not find one. All the inmates are more or less in a state of unhealth from one cause or another: the distinction between chronic cases and acute cases is a vicious one from the point of view of scientific medicine, and all who know the facts are aware that a very large proportion of the so-called chronic cases in the Poor Law institutions were and are so because there is neither personnel nor equipment for their proper investigation and treatment.

The Council of the Association would be doing a much-needed service to the public and to medicine if it supported the view that the service to the sick of the nation should be *one* and organized as *one*. At present it is supporting action which cuts right across this vital point.—I am, etc.,

K. W. MONSARRAT,
Liverpool, May 2nd. Member of the Public Assistance Committee, Lancashire County Council.

REMUNERATION FOR RESEARCH AND INVENTION.

SIR,—In the Annual Report of Council of the British Medical Association for 1929-30, under the section dealing with medical ethics,[1] the Council devotes itself to the consideration of the ethics of remuneration and reward for research and invention, and expresses the opinion that, in view of the fact that a new system of limited and controlled patients is under consideration, it seems desirable that a more general and fundamental statement of the ethical position of the profession in this relation should now be made. Then follows the recommendation:

> That the Representative Body express the opinion: That it is ethically undesirable for a registered medical practitioner who makes an invention or discovery in the medical field to derive financial benefit from the sale of the rights of such invention or discovery, or from royalties for the use of these.

In my view this recommendation is based upon a complete misconception of the object and working of patenting. Not only does it tend to deprive an inventor of the legitimate rewards for his work, but, by discouraging the prosecution of research, it constitutes an actual disservice to the British public and humanity in general. The patent law is framed, not in the interests of the patentee, but of the public. It is designed to secure the maximum of knowledge and improvements in the public domain, and it only gives to the inventor a short monopoly in compensation for his work. Medical research, like other branches of scientific investigation, is very expensive, and takes up much time. Without some means of remuneration all medical research, except such as is carried out by public institutions or specially endowed from public funds, would become impossible. Moreover, such an embargo acts as a great obstacle to the prosecution of research by manufacturers of medicinal chemicals and appliances. Unless these are given a temporary monopoly in the results of their work, which otherwise could be exploited by competing firms who have had no expense in connexion with it, they have no incentive to engage in research at all. For these reasons many valuable discoveries which would have been of great service in the relief of sickness and pain can never see the light, others are stillborn, and many are probably never even conceived. If the patent law is of service to the community in regard to mechanical and chemical inventions it

[1] *Supplement*, April 19th, 1930, pp. 130, 150.

is equally so in regard to medical inventions, and full use should be made of it to stimulate and encourage discoveries in the medical field.

The suggestion of "dedicated patents" is in my opinion equally misconceived and useless. It deprives the inventor of the just rewards for his work, and therefore discourages invention nearly as much as complete prohibition of medical patents. The Medical Patents Trustee would obviously be compelled to grant licences to *all* manufacturers desiring them. Such licences would be of little value to any one firm, and they would seldom be sought. In most cases, therefore, the invention would fail to find commercial support.

It will be observed that the Council's recommendation is of a sweeping character; there is no saving clause as to country. The registered medical practitioner is to be considered as acting unethically if he or she derives financial benefit from the sale of the rights of such invention or discovery, or from royalties from the use of these in any country whatsoever, including countries which cannot be affected by the pronouncements of the Representative Body of the British Medical Association. But the foreign medical practitioner will not be debarred from holding medical patents and exercising his legal rights of monopoly profit and interest in this country.

The term "invention or discovery in the medical field," which forms an essential definition in the Council's recommendation, is not all-embracing. How are we to classify an invention or discovery of a new form of matter by a registered medical practitioner (who is perhaps working in conjunction with a research chemist) which is primarily intended for application in the arts, but which on further research, or with slight modification of an "intermediate" compound—in itself a discovery—is capable of medicinal application? How, for instance, are we to classify a newly discovered substance capable of and intended for use in the arts as a solvent, which, with or without additional invention or discovery, is also found to act as an efficient vermifuge? In short, are we to abolish in this country the possibility of effective co-operation between research workers who are registered medical practitioners and research or manufacturing chemists?

With regard to certain inventions and discoveries, particularly in the case of appliances capable of use clinically or in the laboratory, in lieu of patenting to protect the interests both of inventor and manufacturer, recourse is often had to registration of design or trade mark, usually in the name of the manufacturer. Is it also intended to declare this procedure unethical where the inventor (or associate inventor) is a registered practitioner?

The existing patent law secures by its operation the maximum of knowledge and the transference of the benefits of such knowledge to the public, and it only gives the inventor a short monopoly in compensation for his work. The dependants of the inventor must still be considered as having the right to benefit and profit by his discoveries. Or is the proverbially "poor and needy inventor" to be doubly victimized by reason of the fact that he is a private practitioner and thus eternally deprived of all chance of making provision for himself or for his dependants either in sickness or in old age? For this, and this alone, will be the ultimate outcome of the Council's recommendation, if adopted.

Happily there is a simple way of circumventing the danger inherent in the proposed recommendation and at the same time reducing it to naught. The registered medical practitioner concerned, anxious to protect his discovery and to secure his own and his family's interests, need only assign his invention *ab initio* to a nominee.—I am, etc.,

Hendon, N.W.4, April 25th. MYER COPLANS.

BED FOR DENTAL EXTRACTIONS.

SIR,—Mr. Dolamore's letter in your issue of April 19th (p. 760) raises some very important points. I think nearly all medical practitioners will heartily endorse his principle of "bed for dental extractions."

The practice of giving ether or chloroform to patients in an upright position in a dental chair and then sending them home sick, shocked, and bleeding is a relic of barbarism which should be completely done away with. The more obvious disadvantages of working in the surgery are: (1) the patient is usually not properly prepared, and (2) the operation is rushed, with the all too frequent result that teeth are broken, alveolar margins splintered, gums torn, and bleeding insufficiently checked before the patient comes round. Undoubtedly, therefore, all extraction operations requiring more than a single application of nitrous oxide should be done in the patient's house or in a nursing home.

It is difficult to see, however, why the "onus is on the medical adviser." Surely it is only rational that the dental surgeon who is to perform the operation should also be responsible for the general arrangements, preparation of the patient, and the after-care, just as is the case in any other branch of surgery. One cannot imagine a surgeon casually turning up to perform an operation, having made no arrangement except to fix the time, yet it is by no means uncommon for an anæsthetist to arrive at the time arranged by the dental surgeon and find nothing at all prepared.

It is not always realized that dental extraction can be something more than a minor operation, and may require a prolonged anæsthesia. It should have the same careful arrangements as a surgical case. The dentist, having examined the patient and decided what he is going to do, should consult the doctor (and anæsthetist if employed) with regard to time and place of operation, give the patient full instructions about preparation, and send a nurse beforehand to fix up an operating table, provide towels, hot water, etc., prepare and warm the bed, and give any premedication required.

In any operation which is likely to be prolonged the anæsthetic should never be administered with the patient upright in a chair, but in a prone position on a table (not a bed) placed conveniently for the light. Induction should be deliberate and the further course maintained by means of a vapour delivered through a tube *per os*, or more conveniently through the nose. In this way a smooth, even, light anæsthesia can be carried on indefinitely without periodic interruption from the anæsthetist, enabling the dentist to do his work unhurriedly with frequent swabbing so that he can see as well as feel what he is doing, with the minimum of trauma and the least possible risk to the patient. The operation can be carefully completed, septa broken down, splinters removed, and sockets cleaned. The patient may then be lifted into bed to recover.

There are two reasons usually put forward by those who prefer the upright position: (1) that otherwise teeth, stumps, or fillings escaping from the forceps may be swallowed or find their way into the trachea; (2) that much better leverage can be obtained in this way. The first seems to be an exaggerated danger and much less likely to happen than collapse under the anæsthetic. It can be totally eliminated by giving the vapour through the nose and packing the mouth with gauze, periodically replaced as it becomes saturated. The second is only of importance when the operator has to work in a hurry, and does not arise when the patient is properly prepared and anæsthetized.

All patients should have atropine, which keeps the mouth dry, and adults should have a little morphine. There is then no need to abolish the reflexes and less risk of inhalation of foreign material. One cannot too strongly deprecate the use of a mask or cloth placed over the mouth, since this must be periodically removed, the resulting anæsthesia being alternately deep and light; and one reason why dental surgery is so frequently hurried is the instinctive desire on the part of the dentist to do as much as possible before the mouth is again closed.

In spite of the cordial relations that exist in individual cases there is in general a want of co-operation between doctors and dentists. Far too often patients consult dentists on their own and extractions are carried out of which the doctor is completely ignorant until he is consulted about subsequent complications. We do not see enough of each other's work. Meetings at which both doctors and dentists could be present would probably help us to understand each other's problems.—I am, etc.,

Dundee, April 27th. A. H. MACKLIN.

TRAUMA AND SEPSIS IN THE CAUSATION OF ANAEMIA.

SIR,—A short time ago I received a letter from the Ministry of Pensions in which the following statement occurred: "It cannot be admitted that either traumatism or sepsis has been established as a cause of leukaemia." In an exhaustive article on leukaemia in the eighth volume of *Spezielle Pathologie and Therapie innerer Krankheiten*, edited by Kraus and Burgsch, von Domarus, speaking of traumatism, says: "One cannot maintain that up to the present there is any existing observation showing with sufficient certainty the supposed connexion" (between trauma and leukaemia). And further on: "That an injury can make a till then latent leukaemia so much worse that the patient may become conscious of his illness, and in certain cases the illness may in consequence of the injury lead to an earlier death, cannot be doubted."

On the subject of sepsis von Domarus is more definite, as the following quotation from the same article shows: "At least it cannot be denied that among the many clinical observations that have been made to date there are many points which even to the most sceptical suggest a connexion between leukaemia and infection." And in a later passage he supports his argument by calling attention to the myeloid metaplasia especially of the spleen associated with sepsis.

The Ministry of Pensions is undoubtedly correct in stating that *it has not been established* that either traumatism or sepsis is a cause of leukaemia, the cause and nature of which are as yet entirely unknown, but I would be glad if those of our profession with experience of the disease would express in the *Journal* their views on the statements of von Domarus. The view of the Ministry of Pensions has more than an academic interest, but at present I am concerned only with the scientific aspect of the case.—I am, etc.,

Kensington, W., April 29th. HAROLD H. SANGUINETTI.

ANTIMALARIA MEASURES.

SIR,—It would be very regrettable if, as Colonel Gill declares, the claims of the old school of malariologists are discouraging further research in the field of malaria, for it must be conceded that present methods may be somewhat expensive, and occasionally have proved impracticable. Every worker in the Tropics looks hopefully for the discovery of a drug with which the disease can be cured—that is to say, the patient rendered free of the parasite in all its stages by the administration of a few doses. But, until such time as knowledge makes further advance possible, it would be foolish to scrap what we already know, with nothing to take its place.

Discouragement of those working with such methods as are already known will serve no useful purpose, and may so impress the laity as to do a lot of damage; it is to be hoped that the modern school, which has as yet produced nothing tangible, will not generally adopt the attitude of Colonel Gill, who goes so far as to accuse the old school of making "unsubstantiated claims regarding their successes," and appears to consider all antilarval work useless. Even the layman will hardly swallow this, and such overstatements will hardly shake the confidence of those working on antilarval lines.

Antilarval measures appear to have been but little tried in the past in India; certainly nothing was done in Assam, the most malaria-ridden province. A few spasmodic efforts were made in other provinces, and these unfortunately were notorious failures, thus throwing India back a generation. Antilarval methods cannot uhually be employed in a haphazard fashion, but require for prospects of success that a thorough study should be made of existing conditions, more especially of the carriers and their habits; the results achieved in Malaya were based on the correct differentiation of anopheles species by the entomologists. It is only very recently that India has been in a position to begin operations, for at the time of the earlier experiments much confusion existed regarding the various species, and there was not one whole-time entomologist employed on the subject in the whole of India, consequently failure was not surprising.

Assam has thoroughly tried out the use of quinine, and all those best in a position to judge agree with Sir Malcolm Watson in considering it valueless for the control of malaria. Until such time as the modern school can offer something more promising than quinine and improvement in economic conditions—the latter a very doubtful factor—it is unreasonable to depreciate methods which, *pace* Colonel Gill, have in other countries been efficacious, and, judging by their partial success already in Assam, promise more in the future.—I am, etc.,

London, S.W.15, April 29th. R. A. MURPHY.

COITUS IN PREGNANCY.

SIR,—The part played by the husband in the causation of albuminuria and eclampsia has, so far as I am aware, never been considered or discussed. Over 50 per cent. of these cases occur in young or recently married primiparas—namely, at a time when sexual intercourse is most frequent. Albuminuria is a common sequel of excessive sexual intercourse. In parts of England the belief is commonly held that to ensure easy labour sexual intercourse should continue as usual, and doubtless it does so continue in the majority of first pregnancies. Recently attention was drawn in the *Journal* to the fact that during the war the incidence of eclampsia in Germany was considerably lessened, the reason assigned being scarcity of protein in the diet; the fact that the husbands were absent at the front during practically the whole pregnancy is equally worthy of consideration. It seems probable also that the husband often plays a considerable part in the production of puerperal sepsis; many labours are started prematurely by a drunken and vigorous husband forcing sexual intercourse.

As far as I can gather, albuminuria and puerperal sepsis are far rarer in the animal than the human world; the only practical difference in the two pregnancies is that coitus does not take place in the former and it does in the latter. Some information might be gained on this point from medical missionaries working on the west coast of Africa, as among West African tribes whose ceremonial includes the Bundu a woman is taboo for sexual intercourse from the time she misses her monthly period until the period reappears or she has weaned a child—about twenty months.—I am, etc.,

F. W. COTTON, Lieut.-Col. R.A.M.C.

Wyndham, West Australia, Feb. 11th.

Obituary.

SIDNEY COUPLAND, M.D., F.R.C.P.,

Consulting Physician, Middlesex Hospital.

DR. SIDNEY COUPLAND died at his residence, Wootton Ridge, Boar's Hill, Oxford, on April 29th, at the age of 80. Born December 3rd, 1849, he was the third son of the late W. N. Coupland of Streatham. From Hove House School, Brighton, he went to University College, London, and obtained the M.R.C.S. diploma in 1871. He graduated M.B. with honours at London University in 1873, taking the M.D. degree in the following year. Soon afterwards he became attached to the Middlesex Hospital, and was appointed assistant physician, becoming full physician and being elected F.R.C.P. in 1880.

Dr. Coupland was a keen clinician, and spent many hours in the wards teaching and keeping detailed notes of his cases. His assumption of the duties of full physician was marked by his diagnosis of stone in the kidney of a young girl and the successful performance of nephrolithotomy for the first time in this country by Henry Morris. The next twenty years were fully occupied by a series of appointments in the medical school, where he successively held the offices of tutor, lecturer in practical medicine, pathologist, and lecturer in pathological anatomy, and then lecturer in systematic medicine. All these duties he carried out with characteristic energy and thoroughness, at the same time contributing liberally to medical literature. Dr. Coupland was honorary secretary to the Pathological, Clinical, and Epidemiological Societies before their amalgamation, and was subsequently a Fellow of the Royal Society of Medicine.

Among his early publications were: Goulstonian Lectures on Anæmia (1881), "Malignant Endocarditis" (*Med. Times and Gazette*, 1882), "Salicylate of Soda in Rheumatism" (*Lancet*, 1882), and "Cold Bath Treatment of Enteric Fever" (1884). In connexion with the Royal Commission on Vaccination, he contributed the reports on small-pox outbreaks in Dewsbury, Leicester, and Gloucester (1892-95). During this period also Dr. Coupland, jointly with Dr. Sturges, published *Natural History of Pneumonia* (1899), the articles "Abdominal Tumours," "Intestinal Obstruction," and others in Fowler's *Dictionary of Practical Medicine* (1889), and edited Dr. Wilson Fox's *Treatise on Diseases of the Lungs* (1891). In 1898 he resigned his position as physician to Middlesex Hospital on his appointment as a Commissioner in Lunacy, which he held until 1921. The duties of this office were continuous and exacting, and the only extra effort permitted was the delivery of the Harveian Oration in 1915.

In his early days Sidney Coupland was of a shy and retiring disposition to a degree that certainly interfered with his success as a consulting physician, but his amiability and enthusiasm in work endeared him to the students of his time, who found him always accessible and helpful. Nicknames are a token of affection, and the sobriquet "Kidney Soupland" was inevitable in association with his notable achievement in connexion with the first nephrolithotomy.

A full, useful, and distinguished career is now completed: first as a diligent and distinguished student in the days when facilities for learning were not available as they have become since; then twenty years as a hospital physician with invaluable opportunities for benefiting humanity and advancing the practice of medicine; followed by a still longer period in the service of the State—all ably and willingly performed, leaving a residue in the evening of life for quiet contemplation and the encouragement of those who follow.

Dr. Coupland married in 1880 Bessie, daughter of the late Thomas Potter, of Great Bedwin, Wilts, who survives him, with one son, who is Beit Professor of Colonial History at Oxford.

EDWARD LAW, M.D.,

Formerly Surgeon to the London Throat Hospital

Dr. EDWARD LAW, who retired from practice in 1918 and died last week at the age of 77, was a much respected figure in medical London for many years. He was by birth a Yorkshireman, but most of his medical education was obtained at the University of Edinburgh, where he graduated M.B., C.M. in 1877, and M.D. in 1880. He studied otology in Vienna and established himself in practice in London. He was originally on the staff of Golden Square Hospital for Diseases of the Throat, but along with the late McNeil Whistler, Edward Woakes, and George Stoker he assisted in founding the London Throat Hospital in Great Portland Street, and confined his public activities to that institution, where for many years he was on the staff. A distinguished member of the British Medical Association, he was vice-president of the Section of Otology at the Annual Meeting in London in 1895, and of the Section of Laryngology at the Meeting in 1902 at Manchester. He presided over the Section of Otology when the Annual Meeting was again held in London in 1910. He was also president of the Otological Section of the Royal Society of Medicine in 1909.

Law was highly esteemed in every circle in which he moved. The estimation in which he was held by those under whom he studied in Vienna is shown by the fact that Professor Gruber entrusted to him the task of translating into English his work on diseases of the ear, and that Professor Politzer included him among the four distinguished friends to whom he dedicated his great *Lehrbuch der Ohrenheilkunde*. It will be agreed that an exceptional delicacy of touch enabled him to apply in practice his great sympathy with sufferers and his intense objection to causing pain. He was very conservative in his treatment, and attracted many patients who would have proved intolerant of other hands. Among those who consulted him were some of the highest in the land.

Like many of his fellow Yorkshiremen Edward Law expressed his opinions with a degree of downrightness which belied his kindness of heart. It might be said that he was without guile, and that "you always knew where you were with him." His geniality and his sincerity endeared him to his many warm friends, and called for respect from those who only knew him at a greater distance. He had the talent for making friends and keeping them. One who knew him has expressed the opinion that he was "a friend to many and an enemy to none." With this the writer is in entire agreement.

J. D.-G.

DAVID DICKIE, D.S.O., F.R.C.S.Ed.

Surgeon to the Northern Infirmary, Inverness.

WE regret to record the death, on April 29th, of Mr. David Dickie, who for several years had been surgeon to the Inverness Northern Infirmary. He was born in 1880, and received his medical education at Glasgow and the Royal College of Surgeons, Edinburgh. He graduated M.B., Ch.B.Glas. in 1903, and three years later obtained the diploma F.R.C.S.Ed. After holding the appointments of senior resident to the Royal Hospital for Sick Children, Glasgow, and senior resident medical officer to the Maternity Hospital, Glasgow, he became surgeon to out-patients at the first of these institutions and to the Western Infirmary, Glasgow; he was also assistant to Professor Munro Kerr, thus obtaining a wide surgical experience. He served with distinction as a surgeon specialist in France and Italy during the war, and was awarded the D.S.O. In 1920 he was appointed surgeon to the Northern Infirmary, Inverness, and he was also surgeon specialist to the Northern Area under the Ministry of Pensions. He was a member of the British Medical Association. He contributed articles on surgical subjects to the *British Journal of Diseases of Children* and to the *British Dental Journal*.

Mr. Dickie had built up a widespread consulting surgical practice in Scotland, his operative skill winning the implicit confidence of his professional brethren. Owing to ill health he found it necessary to resign his position on the staff of the Northern Infirmary, very much to the regret of the directors and his colleagues there. His frank, cheery nature endeared him to his numerous friends and patients, and his surgical knowledge was the means of saving many lives. He is survived by his widow, with whom deep sympathy is felt.

THE LATE DR. F. E. WYNNE.

PROFESSOR EDWARD MELLANBY, M.D., F.R.S., sends the following tribute:

Dr. F. E. Wynne came to Sheffield as medical officer of health in succession to Dr. Harold Scurfield nine years ago, and during this period it has been my great privilege to be on close terms of friendship with him and his family. I should not like the opportunity to pass without testifying to my appreciation of this friendship and expressing my admiration of his many fine qualities. It is seldom that anyone is blessed with so many gifts as those possessed by Dr. Wynne. He was a man of high culture, of great sensibility, with a keen appreciation of "all things bright and beautiful," and he had withal a distinctive power of grasping the relative importance of matters of practical interest. In addition, he was endowed with the means of expressing himself both by the spoken word and in writing to a degree possessed by few. His knowledge of English literature was profound, and to me one of the greatest treats I have experienced has been to listen to Wynne discussing Wordsworth, Byron, Trollope, and many other poets and writers. Of modern writers he particularly admired George Moore, and especially his book *The Brook Kerith*. He made a practice of reading aloud to his family, and on many occasions an invasion of his home in the evening has revealed him in this act. He was not content, however, to be merely an admirer of good literature, for he himself had great gifts in this line. His work as a doctor and administrator of public health prevented his full development as an author, but anybody who reads his novels,

particularly *The Mediterranean Mystery* and *Digby's Miracle*, can appreciate that in other circumstances he could have been a first-rate writer. In his earlier years he wrote a play that was good enough to be produced by Miss Horniman in Manchester; of its merits I can say nothing, but it had the misfortune to be produced when the great war started, and thus was lost. For many years Wynne acted as medical correspondent to the *Manchester Guardian*, and it is well recognized that the articles on medical topics for the laity appearing in that newspaper reached a much higher standard than those usually found in the lay press. With Wynne's work as a public administrator I am not sufficiently familiar to write. He was a man of strong views, and he had unlimited moral courage to guarantee their expression to the discomfort of many people. Possibly as an administrator he was too idealistic and too intolerant of anything of the nature of a placebo. He was a whole-hogger for preventive medicine, and was dreadfully impatient of much in the present-day treatment of disease, especially as it often has to be applied by the general practitioner in the form of a bottle of medicine. His impatience in this respect was without doubt the reason why he gave up practice and entered the public health service. It will be clear that a man with such great gifts, associated with charm of disposition and a kind nature, had a friendship to offer which will always remain a pleasant memory.

DR. WILLIAM STANLEY GEORGE, who died on April 12th, was a prominent medical practitioner in Hampstead, where he won wide popularity. He was born in 1885 and received his medical education at Guy's Hospital, where, in 1912, he graduated M.B., B.S.Lond. and obtained the diplomas M.R.C.S., L.R.C.P.; seven years later he proceeded M.D. After holding house appointments at Guy's Hospital he obtained a commission in the R.A.M.C. and acted as anaesthetist to the 42nd Stationary Hospital. At the end of the war he returned to Hampstead, where he built up a large practice, taking an active part in the work of the British Medical Association. He was chairman of the local Division in 1924, and for many years represented it on the Branch Council; at the time of his death he was a member of the Executive Committee of the Division. In 1922 he was elected to the Hampstead Borough Council, and for two years served as chairman of its Public Health Committee; he was the chairman of the Establishment Committee when he died. He leaves a widow and three children.

DR. THOMAS ARCHER COLT, O.B.E., who died on April 23rd, after an operation, at the age of 78, was a brother of the Rev. Sir Edward Dutton Colt, Bt., to whom he was heir-presumptive. He received his medical education at Bristol and University College, London; in 1879 he obtained the diplomas M.R.C.S.Eng. and the L.R.C.P. and L.M.Ed. He commenced practice in Portsea and Southsea more than fifty years ago in partnership with the late Dr. A. N. Garrington, and for thirty years he was Poor Law medical officer for Portsea. During the war he was in charge of the Branksmere Auxiliary Hospital, Southsea, and was created O.B.E. Dr. Colt was a member of the British Medical Association, and had been chairman of the Portsmouth Division. He retired from practice about eight years ago owing to almost total blindness. He was twice married, and leaves a widow and family.

The death of Miss M. B. WILLIAMSON, assistant secretary of the Royal Society of Medicine, deprives a great organization of a woman to whom the successful development of the society during the last thirty years is very largely due. Miss Williamson first worked as a temporary assistant in the late nineties until she was taken on the permanent staff in 1904. Under the guidance of the then secretary (the late Sir John MacAlister) she soon proved to be an invaluable member of the staff. During the difficult times in the society's history, immediately before and after 1907—the year in which the Royal Medical and Chirurgical Society became the Royal Society of Medicine—she was the right hand of the secretary and honorary officers. In 1911, when the building at 1, Wimpole Street was being erected, and in 1912, when the arduous task of transferring the property of the society from 20, Hanover Square and installing it in the new house had to be faced, she was the life and soul of the organization. Again, when many of the staff and honorary officers were on active service, her unflagging energy and cheerfulness enabled her to undertake and perform with amazing efficiency tasks which might well have discouraged and deterred a less ardent spirit. From 1920, when Sir John MacAlister's health broke down and until his retirement in 1925, Miss Williamson was able to supplement his failing powers to such good effect that the work of the society did not suffer. In 1925 the council passed a special resolution of gratitude and appreciation of her fine service, and later in that year it was by her hand that the memorial portrait of Sir John MacAlister was unveiled. Miss Williamson's vast knowledge of the history of the society, of the manifold details in its working, her outstanding powers of organization, and her devotion to the society which it was her delight to serve, were all offered to his successor as loyally as they had been to Sir John. She was a little woman of abounding energy and vitality, her sense of duty was nicely balanced with a sense of humour, and with a great dignity there went a kindliness that endeared her to all those who had the privilege of working with or for her. Her powers were preserved in all their fullness up to the beginning of the short illness which caused her death, and the last words she spoke were of the society which had been the object of her lifelong service. She was known to nearly every Fellow, and her loss will be felt as that of a personal friend by many hundreds of those associated with the society.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons this week completed the report stage of the Budget resolutions. The second reading of the Consumers Council Bill, which provides for the investigation and control of prices, was the business of the Commons for May 8th. The House of Lords had arranged to take the committee stage of the Workmen's Compensation (Silicosis) Bill on May 7th. No date has yet been named for the resumed debate on the Mental Treatment Bill in the House of Commons.

The Parliamentary Medical Committee proposes to discuss rheumatism on May 13th.

Ministry of Health Estimates.

In the debate on the Ministry of Health Estimates—reported in part on page 845 of last week's issue—the chief topic under discussion was the recent report of the Government actuary on the increase in sickness benefit under the National Health Insurance Act.

Sir DONALD MACLEAN said that he did not deny that advantage was taken in many quarters of the facilities for getting sickness benefit, but after the year 1926 there was a decline in the vitality of millions of people. What was required was an intensive internal examination into the whole problem by all the sub-departments concerned. The Minister of Health's announcement on post-graduate schools dealt with one of the most important projects undertaken for many years. Recently a commissioner appointed by the British Medical Association made a tour of Australia and New Zealand. He would give a quotation from a letter which he received from the immediate past-president of the British Medical Association:

"On my visit to Canada and my recent tour to the Branches of the British Medical Association in New Zealand and Australia—notably the Congress at Sydney as well as at Brisbane, Melbourne, Tasmania, Adelaide, and Perth, and again in Ceylon, Bombay, and Cairo—I was profoundly impressed by the constantly reiterated inquiries as to the prospects of the establishment in London of well-organized facilities for post-graduate study and research. I believe the scheme submitted will go far to meet this urgent demand from our medical colleagues throughout the Empire—at home as well as overseas—and that in its fuller developments it will constitute London, what she should long ago have become, a world medical centre for post-graduate work of the highest standard."

DR. MORRIS-JONES said that he was sorry the Minister did not mention vaccination. That would have to be faced. There were also international obligations associated with it. A short time ago, when we had an epidemic in this country, our neighbour across the Channel raised difficulties about people arriving from this

country. At present the administration of the law with regard to vaccination was almost farcical. If it was the opinion of the Government that vaccination should be compulsory it ought to be made compulsory. If the Government did not agree in that sense, steps ought to be taken to abolish compulsory vaccination. He spoke of the effect of the Local Government Act of 1929 on men and women who had given voluntary services on public bodies. In his own municipality there was the case of a parish doctor who had been on the county council since the beginning of that authority. Under the Act that doctor had to take the choice of resigning an appointment which he had held for thirty of forty years or resign his membership of the local authority. Such people knew that if they gave up their appointments and continued to serve in a voluntary capacity on the public authorities they would lose all superannuation payments, towards which they had contributed over a series of years, as well as the State contribution. He hoped that the Government would find a way of redressing this anomaly. Turning to the claims under the National Health Insurance Act, he agreed with Mr. Rhys Davies that the main cause of the increase was the industrial depression since the war. There were amendments of the National Health Insurance Act whereby persons who were unemployed were still able to retain their rights to medical benefit. From his experience as a medical man he found that enforced idleness was bound to cause more sickness. The man who was working was much healthier than the man who was not working. There was also increased illness as a result of the war, even among those who did not participate as combatants. Many insured persons had suffered from the bombing that took place in London. Hundreds of people in the county of London were directly or indirectly suffering as a result of the experiences which they went through at that time. There was another reason for the increased claims. He agreed with Mr. Rhys Davies that 99 out of every 100 national health insured persons were honest, but that 1 per cent. were malingerers. He had persons who had come to him, as a medical practitioner under the Act, and said: "We have been paying long enough." One person said: "We have been paying to Lloyd George for years, and it is time that we got something out of it." The giving of medical certificates was a very difficult matter. Medical men were neither worse nor better than any other class of human creature, and were confronted day by day with very great difficulties under this Act. One member had suggested in the debate that a young medical man, newly qualified and anxious to build up a practice, would be rather keen to please his patient, and therefore he would possibly give a certificate when it was not really required. Such cases were very rare. It was extraordinarily difficult to tell when a man was or was not capable of work. One of the most difficult things in the world was to prove that a man was not ill. He hoped the Minister of Health would be able thoroughly to overhaul and reorganize the whole scope of the national health insurance service in this country. He hoped the Government intended before long to bring before the House a scheme to enlarge the whole service of national health insurance, co-ordinating its numerous branches and bringing within its scope women and children and dependants.

Dr. MORGAN, as one who administered the Act every day, said that from the medical point of view there was no general laxity of certification on the part of the medical profession. There was no general malingering. People were getting to have a knowledge of their rights, and were demanding them more and more. Certain societies and their agents had tried to excite a feeling against the medical profession for what they thought was laxity. They forgot that, at the same time, the insured person was being educated in his rights against approved societies. He knew now what he was entitled to, and that when he was ill he could receive the benefits for which he paid. What was more, his employer was much more keen now that his employee should come under the Act and get its benefits. A larger number of the population were taking advantage of the Act, but they were ill, and the plea that the increase was due to malingering or laxity on the part of the doctor was not true. The Insurance Act was not brought into existence for the sake of the approved societies, the doctors, the chemists, or the State, but for the benefit of the insured person, and the individual insured person had enough to suffer. There was equality of payment, but not of benefit. A man might have registered in Manchester, become unemployed, go to London, choose another doctor, and get ill. Then there was a whole series of performances to go through, sending certificates to Manchester, and so on, before he could get the benefit. The whole system was riddled with anomalies to the disadvantage of the person for whose benefit the Act was introduced, and because approved societies wanted to hide the charges against themselves for their administration of the Act they levelled charges against other people. The sooner somebody in the country called for a league of insured persons and made them pay, say, a penny a month to see they got their benefits and rights under the Act, the better it would be. They required to be protected not only from the doctors, but from the chemists, the societies, and the State. The sooner that was done the sooner, too, would be brought about the changes recommended by the minority of the Royal Commission—hospitals, convalescent treatment, dental treatment, and eye treatment—not only for those who happened to be in favoured rich societies, or favoured rich occupations, but all insured persons. He was sure, from discussion with medical men all over the country, that there was no malingering on the part of the insured person and no lax certification on the part of the doctors.

Dr. FREMANTLE said they were much relieved to hear that the question of excessive claims for insurance benefit was under further examination. Mr. Rhys Davies had suggested that the experience of the first three months of this year indicated that this phase was coming to an end, but he (Dr. Fremantle) doubted whether such a steady rise going on year after year would terminate so quickly. Among both medical men and insured persons there were a certain number who had less conscience than others. Ordinary human beings tried to get the most out of a State service. No one was more responsible for this attitude towards national insurance than Mr. Lloyd George, who managed to send the cry "ninepence for fourpence" throughout the country. Now the disadvantages of it were prevailing on the insurance scheme. Let them contrast that with the old system of the friendly societies, which induced a spirit of loyalty among the members. Then there was a tendency among the members to make the best of things and come on the funds as little as possible. They had to try to encourage the old spirit which formerly attached to friendly societies. They had to cultivate the spirit of loyalty with friendly societies on the one hand and with medical men on the other in order to get through the difficulty. It was no use trying to coerce any body of professional men, most of all medical men, because they had always got the whip hand in the end. They alone understood the technicalities, and it was necessary to work with them. The Ministry of Health had been extraordinarily sympathetic towards medical men. A medical practitioner whose action was called in question could submit his case, first of all to the judgement of the regional medical officer, and then to a jury of medical men. This would have the greatest effect upon medical practitioners. It was suggested that medical men were too lenient in these cases because they did not want to let their professional down. But the last thing medical men wanted to do was to cover up the misdeeds of those who were letting them down. According to the opinion expressed by the British Medical Association, which represented two-thirds of the medical profession there were a few doctors doing bad work, but these men would be bad under any system. The chief difference between private and insurance practice was that there were penalties in the latter if doctors did not thoroughly examine their patients and were inclined to give certificates for sickness benefit without discrimination. Two particular cases of excessive prescribing had been brought to the notice of the Ministry of Health and had been referred to the referees. In one case the referees upheld the decision of the Minister, but not in the other. It was shown, however, that excessive prescribing did exist. Some of those who wished to support the idea of giving benefit at any price had taken the line that medical men were justified in prescribing to any extent so long as they were doing what they considered best for their patients. The ordinary doctor had been brought up to be fairly regardless of cost in prescriptions, dressings, equipment, and so on, in the hospital, but it was a very different matter when one had to provide these things for himself in private practice. The natural tendency was for a man to use these things without regard to cost, and that tendency must be restrained, without damaging the effect of the service. The only way to do that was to take the profession generally into confidence and get their co-operation. He believed that good machinery had been devised now which would ensure this. He did not believe there was any real increase in sickness among the people. Some of the best and most useful health work done throughout the country was done by voluntary societies and voluntary hospitals, and he hoped that every effort would be made to encourage these schemes in the future administration of local government and of the health services of the country, not least in connexion with the post-graduate hospital. That last scheme had been warmly commended on every side, though, he thought, a little without regard to the difficulties that there must be in enlisting the voluntary skill and experience and efficiency which were at present associated with the medical schools in London and elsewhere in the country. He hoped this new post-graduate hospital would manage in some way to enlist the sympathies and efforts of all the thirteen medical schools in London.

Mr. PERRY appealed to the Minister of Health to sanction the inclusion in additional insurance benefits of treatment at British spas for rheumatism and allied diseases. The British Spas Federation had drawn up a scheme for the consideration of the Ministry and the approved societies. They had come to an agreement with the British Medical Association in regard to the scale of fees under which exactly the same medical service and treatment now given to private patients would be available for insured persons.

Miss LAWRENCE, Parliamentary Secretary to the Ministry of Health, replying to the debate, said that insurance claims had risen steadily from 1921 to 1922, which was the peak year. The number of claims had not been analysed for the two later years, but the figures were dropping now in the earlier months of this

year. It was very remarkable that the duration of sickness had hardly risen at all, but there had been an increase in the number of claims in respect of short illnesses. She asked the committee not to pass any rough-and-ready judgement on this mass of confused statistics. The actuary's report, which had been issued, was one of the most valuable things that either the medical profession or the approved societies had ever had. The Ministry proposed to follow up the report and to give the information year by year. The approved societies and the medical profession had now rather changed their minds, and were inclined to think that a somewhat longer delay before which a patient might change his doctor was necessary. The British Medical Association and the Council of Approved Societies had drawn up a scheme under which they would be able to review the case of any one of their professional brethren.

Dr. MORGAN: Will the hon. lady consider the possibility of a doctor who is unpopular, not for medical reasons, being dealt with unjustly by his colleagues who differed from him not medically, but for other reasons?

Miss LAWRENCE said she thought that the general medical opinion of the district was acceptable for correcting any eccentricity in a medical man.

Sir KINGSLEY WOOD asked if Miss Lawrence would give a little more information to the committee about the new regulation in relation to the penalization of doctors.

Miss LAWRENCE said that the British Medical Association, the Conference of Panel Committees, and the Consultative Council of Approved Societies had agreed that where there was anything abnormal in a doctor's certification a committee should be chosen from the panel doctors in his own area to review the case.

Mr. MCSHANE: Is it not true to say that every one of those doctors who are going to sit in *judgement* is an *interested person*?

Miss LAWRENCE said that was so in a sense. The panel practitioners in a district have a common interest in maintaining the professional prestige of their brethren, and they also have a pecuniary interest in not cutting down too much the fees of any member of their body. They would report to the Minister, who would have in reserve the usual powers, where a case was proved, of deducting something from the remuneration of the practitioner concerned.

Captain GUNSTON: Would the hon. lady say what action is going to be taken if it is found that a doctor has behaved wrongly? Is he going to be debarred from practice?

Miss LAWRENCE said the usual method was to make a certain deduction from the remuneration of the doctor concerned.

Mr. T. LEWIS: Will the approved societies or insurance committees have any part in this review?

Miss LAWRENCE: No. It has been agreed that it shall be the panel doctors in the locality who will investigate such matters.

As previously reported, the debate was adjourned.

On April 29th Miss LAWRENCE, replying to Sir F. Hall, said that, according to a report recently furnished by the Government actuary of the sickness and disablement benefit experience of a representative sample of the whole body of insured persons, the number of insured men per 100 who claimed sickness benefit in 1921 and 1927 was 14 and 23 respectively. The amounts expended under the Health Insurance Acts in England and Wales in 1921 and 1927 in respect of sickness benefit were £7,176,800 and £11,818,000 respectively; of disablement benefit, £2,689,600 and £6,368,000 respectively; and of medical benefit, £9,394,800 and £8,772,500 respectively. In this connexion it was pointed out that the increase in the amounts expended on sickness and disablement benefits in 1927 as compared with the corresponding amounts expended in 1921 was, to some extent, due to the fact that in the later of those years there were larger increases in the benefit rates under the societies' schemes of additional benefits. The cost per head of the population of England and Wales in 1921 and 1927 for national health insurance was 13s. 11d. and 18s. 8d. respectively, and of medical benefit provided under the Health Insurance Acts 4s. 11½d. and 4s. 5½d. respectively. The factors which had contributed to the increases above noted were numerous and complex, and without further and fuller consideration the Minister of Health did not think it possible to make any general statement as to the relation between those facts and the increased provision of curative and preventive treatment.

Indian Medical Degrees.

On May 5th Mr. BENN told Mr. Freeman that a proposal for the constitution of an inter-university medical board consisting of representatives of the Government of India and their universities pending the establishment of an all-India council, was made to the Government of India by a conference of Indian universities last October. It was referred to the General Medical Council, whose executive committee adopted, on February 24th, a resolution stating that it was unable to accept the proposal as furnishing a satisfactory method of supplying the Council with authoritative information on medical qualifications in India, and with the necessary guarantee [illegible] Mr. Benn, in a further reply to Mr. Freeman, who asked if it was proposed to revive the competitive examinations for admission to the Indian Medical Service, said the Government of India proposed to send him their considered views, which he expected shortly.

Housing (Scotland) Bill.

A Standing Committee of the House of Commons, on May 6th, began consideration of the Housing (Scotland) Bill. Clause 1 provides that on a report by the medical officer of health, or on other information, a local authority may, if it is satisfied that an area is an unhealthy area, pass a clearance resolution. Dr. ELLIOT moved to leave out the provision that the authority should act on the report of the medical officer or on other information, in order that all available sources of information should be open to the local authority. Several members urged that sanitary inspectors as well as medical officers should be entitled to present reports to local authorities. The Government took the view that the amendment would weaken the bill and would play into the hands of authorities that were laggard in slum clearance. The amendment was rejected.

National Health Insurance.

On May 1st Mr. GREENWOOD, replying to Mr. Hayday, said that the total of the surplus funds of approved societies and branches under the Health Insurance Acts was ascertained by quinquennial valuations. The results of the last completed valuations were summarized in the report of the Government actuary, dated November 25th, 1926. That report stated that the total surpluses amounted to £42,413,319, from which amounts totalling £26,619,161 were certified for distribution in additional benefits in the ensuing quinquennium; of this distributable surplus £13,345,000, or about one-half, was applied by the societies and branches concerned in providing increases of the statutory cash benefits, and the remainder for the provision of various treatment benefits. The most important of these benefits, and the annual sums made available for them during the period of the schemes (including the State grant), were: *dental benefit*, £2,900,000; *ophthalmic benefit*, £470,000; hospitals, £324,000; convalescent home treatment, £235,000; *medical and surgical appliances*, £142,000.

Mr. Greenwood, on May 6th, also told Mr. Hayday that the total number of persons in Great Britain entitled to benefits under the National Health Insurance Acts on December 31st, 1920, was approximately 15,200,000. The corresponding number on December 31st, 1929, was 17,800,000, of whom about 880,000 had ceased by reason of age to pay contributions under the Acts and to be entitled to sickness and disablement benefits. The number of insured persons who, up to December 31st, 1929, had ceased to be entitled to sickness and disablement benefits by reason of the reduction of the age limit from 70 to 65 was estimated to be about 650,000. These persons continued to be entitled to medical benefit and to any additional benefits in the nature of treatment after attaining 65.

Psittacosis.—Mr. GREENWOOD told Mr. Hacking, on May 1st, that in twenty-four cases of illness commenced during March and two during April patients had been associated with sick parrots. In the present state of knowledge of psittacosis it was not possible to say definitely how many persons were in fact suffering from that disease.

First Aid at Coal Mines.—Mr. B. TURNER, in reply to Mr. T. Williams on May 6th, said that the new regulations regarding first aid at coal mines were compulsory, but he had received no complaints concerning collieries which had failed to carry them out. The regulations, which only came into operation a month ago, involved big changes, amounting at some collieries to a complete reorganization of first-aid work. In some instances it had not yet been possible for this [illegible] be carried out in full, but the matter was [illegible] attention of H.M. inspectors, who would see [illegible] unnecessary delay.

Pensions.—Mr. F. O. ROBERTS, on May 5th, told Major Cohen that up to date about thirty cases of material doubt or difficulty in pension claims outside the seven years' limit had been or were being referred to independent medical consultants. Of these, fifteen had so far been considered, with results unfavourable to fourteen claims and favourable in one. On the same day Mr. Roberts told Major Leighton that about 217 grants had been made, since the passing of the Act, under special sanction to officers and men who had unsuccessfully appealed to the independent tribunal established by the War Pensions Act, 1919. He stated that up to the end of March approximately 225,000 appeals had been made to the Entitlement Appeal Tribunal, including appeals by disabled officers and men and by widows and dependants. Of these, about 55,500 were allowed; the number disallowed, including appeals withdrawn or lapsed, was about 169,000.

Notes in Brief.

Grants recommended by the Development Commissioners and approved by the Treasury, include £65,000 (in addition to £35,000 sanctioned previously) for rebuilding the Royal Veterinary College [illegible] and £4,250 for the extension of the laboratory at the Cambridge [illegible] Department of Animal Pathology.

[illegible] Benn states that, so far as he is aware, no annual contribution [illegible] intermade by the Central Government towards the upkeep of [illegible] we habitutions in India. Public health is a transferred subject, [illegible] Channel der is one for the provincial Governments.

Universities and Colleges.

UNIVERSITY OF OXFORD.

At a congregation held on May 1st the following medical degrees were conferred:

D.M.—R. A. Walsh.
B.M.—R. G. Macbeth, M. G. Pearson.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on May 3rd the following medical degrees were conferred:

M.B., B.Chir.—J. Foster, T. D. W. Fryer, C. J. M. Dawkins.
B.Chir.—T. O. Garland.

Dr. W. E. Dixon, F.R.S., has been reappointed Reader in Pharmacology for five years.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the monthly meeting of the President and Fellows held on May 2nd the following members were duly admitted Fellows of the College: Norman McIntire Falkiner, Edward Thomas Freeman, David Gray, Victor Ormsby McCormick.

Narayan Bhawan Kotak, F.R.F.P.and S.Glasg., having passed the necessary examination, was admitted a Licentiate in Medicine and a Member of the College. Norman Ward Rawlings, L.M.S.S.A.Lond., was, after examination, admitted a Licentiate in Midwifery of the College.

On the recommendation of the Committee of Management of the Irish Conjoint Board of the Royal Colleges, the courses of instruction given at the London School of Hygiene and Tropical Medicine were accepted by the College as satisfying the requirements of the Conjoint Examination for the Diploma in Public Health.

Medical News.

THE next session of the General Medical Council will commence at 2 p.m., on Tuesday, May 27th, when the President, Sir Donald MacAlister, Bart., K.C.B., M.D., will take the chair and give an address. The Council will continue to sit from day to day until the termination of its business.

THE annual dinner of the West London Medico Chirurgical Society will be held at the Trocadero Restaurant, Piccadilly, on Thursday, June 12th.

THE annual summer dinner of the Glasgow University Club, London, will be at the Trocadero Restaurant, Piccadilly, on Friday, May 30th, at 7.30 p.m., with Robert S. Rait, C.B.E., LL.D., principal and vice-chancellor, in the chair. Any Glasgow University men who, though not members of the club, desire to attend are requested to communicate with the honorary secretaries, 62, Harley House, N.W.1.

THE annual medical missionary breakfast of the Medical Prayer Union will be held on Wednesday, May 21st, at the Refectory, University College, Gower Street, W.C., at 8 a.m. An address will be given by Dr. John Kirk of University College, London, late of Kwangtung, China. An intimation of intention to be present will be welcomed by the honorary secretary, Dr. Tom Jays, Livingstone College, Leyton, E.10.

THE Manchester Royal Infirmary Old Residents' Club will hold its triennial dinner in Manchester on Saturday, October 25th. Particulars will be circulated to members in due course, but it is hoped that old residents who have moved far afield will start making the necessary arrangements to be in Manchester for that week-end.

A MEETING of the West Kent Medico-Chirurgical Society will be held at the Miller General Hospital, Greenwich, S.E.10, to-day (Friday, May 9th), at 8.45 p.m. The president, Dr. T. E. White, will take the chair, and deliver an address entitled "Reminiscences and reflections." A smoking concert will follow.

A QUARTERLY meeting of the Royal Medico-Psychological Association will be held on Thursday, May 22nd, at the British Medical Association House, Tavistock Square, W.C., when Dr. Nathan Raw will preside. Dr. A. A. W. Petrie will open a discussion at 3 p.m., on American psychiatry and the practical bearing it may have in the application of recent Local Government and mental treatment legislation.

FROM May 13th until July 4th the Fellowship of Medicine will hold an evening course for the M.R.C.P., consisting of lectures by experts in their particular branches of medicine and demonstrations in medical ophthalmology. Unless otherwise stated, the lectures will be delivered at the Medical Society of London, 11, Chandos Street, Cavendish Square, on Tuesdays and Fridays, at 8.30 p.m. Dr. J. W. McNee will lecture on May 13th on "Recent views on diseases of the liver and biliary tract," and on May 16th on "The structure and functions of the spleen in relation to its diseases." On May 12th, at 10 a.m., Dr. Stanley Wyard will give a demonstration in the out-patient department at Bolingbroke Hospital, and on May 15th Mr. Herbert Paterson will demonstrate operations and ward cases at 2 p.m. at the London Temperance Hospital; no fee is charged for these demonstrations. From May 12th to 24th there will be a whole-day course at the City of London Hospital for Diseases of the Heart and Lungs. From May 19th to June 7th a course at the Central London Ophthalmic Hospital will consist of instruction in the out-patient department and theatres, including special lecture-demonstrations. A two weeks' comprehensive morning course will be held at the Hospital for Sick Children from May 26th to June 7th; a minimum entry of twelve is required, so early application is desirable. From May 26th to June 7th there will be an all-day course at the Queen Mary's Hospital, Stratford, with especial reference to tuberculosis. Copies of all syllabuses and information on post-graduate work are obtainable from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE twenty-first anniversary of the Men's Union of the Manchester Union was celebrated on May 1st, when honorary membership was conferred on Lord Crawford and Balcarres (Chancellor of the University), Lord Hewart (Lord Chief Justice), Mr. Arthur Greenwood (Minister of Health), Professor A. H. Burgess (President of the British Medical Association), the Dean of Manchester, the Lord Mayor of Manchester, and Mr. C. P. Scott.

AT the annual general meeting of the St. Pancras Division of the British Medical Association, to be held in the London School of Hygiene and Tropical Medicine (Keppel Street, Gower Street) on Tuesday next, May 13th, at 9 p.m., Dr. R. G. Canti will show his cinematograph film of the growth of living tissue.

A CONFERENCE of the British Hospitals Association will be held in Newcastle on June 18th, 19th, and 20th, when there will be an exhibition of plans of recent hospital construction, including furniture and administrative appliances.

DR. ALBERT E. BRINDLEY, medical officer of health for Derby, who is retiring, was entertained to lunch in the Friary Hotel, Derby, on April 26th. At the lunch he was presented with a silver tea-set from his past and present professional staff. Several of his former colleagues attended the function, and Dr. Nash (Hounslow), his first assistant, spoke of the affection and respect in which Dr. Brindley was held by his old friends. Dr. A. R. Laurie (Derby) paid tribute to the work which Dr. Brindley had done in Derby since his appointment in 1907, and said that it would be difficult for anyone to follow in the footsteps of so able a chief. Dr. Brindley briefly responded.

IN connexion with the inauguration of the new museum of hygiene at Dresden this month, an international exhibition of hygiene will open in that city on May 17th, and continue until the beginning of October. The exhibits will illustrate methods of training the public in hygiene, both personal and national; dietetics; general physical culture; mental and occupational hygiene; the campaign against insect carriers of disease; and hospital administration. Inquiries should be addressed to the business manager at the office of the exhibition, Lennestrasse 3, Dresden-A.1.

THE fifteenth French congress of legal medicine will be held in Paris from May 26th to 28th under the presidency of Dr. Dervieux, when the following subjects will be discussed: Sudden death, introduced by MM. Hégen Gilbert, Laignel-Lavastine, and De Lavit; traumatic osteomyelitis, introduced by MM. Leroy and Muller; and criminality in modern society, introduced by M. Costedoat. Further information can be obtained from M. Vernis, 19, Quai de l'Horloge, Paris, VI.

THE Victoria Home for Crippled Children at Bournemouth, conducted by the Shaftesbury Society, is being extended to accommodate twenty more children, and the Russell Cotes School of Recovery at Parkestone is being enlarged to receive an additional thirty boys and girls selected by school medical officers in Greater London.

AS the result of the consumption of the infected flesh of a circus bear, 75 cases of trichinosis have recently occurred at Stuttgart.

AN association of Belgian surgeons has recently been founded under the presidency of Dr. De Beule.

THE clinical report of the Tsan Yuk Hospital and of the Maternity Bungalow of the Government Civil Hospital, comprising the work of the school of midwifery of the University of Hong-Kong for the year ending April, 1929, has been reprinted from *The Caduceus* of November, 1929, in pamphlet form.

PROFESSOR KARL KISSKALT of Munich has been appointed by the Turkish Government director of the Central Institute for Hygiene at Angora.

DR. G. T. LAFORA, an eminent Madrid neurologist, has been nominated president of the Spanish Medico-Chirurgical Academy.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh)

QUERIES AND ANSWERS.

FLEA INFESTATION.

"PULEX," since moving into an expensive modern flat (one in a "converted" group), has been flea-tortured; skin irritation and insomnia are becoming habitual. Scrupulous hygiene, antiseptic soaps and lotions, and insect powder are unavailing. The fleas seem to breed in and under the flooring, which is old, with many deep cracks. Advice is asked regarding prophylaxis and actual treatment of the floors.

TREATMENT OF TACHYCARDIA.

DR. F. J. ALLEN (Cambridge) writes: Calcium lactate, 15 grains per diem, has almost completely banished this trouble in my case, although it had existed about twenty-eight years. Digitalis increased the trouble; possibly it confirms the habit in some cases of so-called "functional" tachycardia, and renders it incurable. If used at all, it should be tried at first in very small doses, after giving calcium lactate a fair trial.

INCOME TAX.

Loss on Subletting a House.

"L. G. S." took a lease of some premises in 1921 with a view to entering into partnership with a practitioner in the town. The partnership negotiations fell through, and he was unable to sublet the house, except for a smaller rent than he has to pay. He is now in practice elsewhere; can he claim any allowance for the amount of the annual loss in rent?

*** The loss does not arise in the carrying on of his present practice, and we see no ground on which he can legally claim any allowance. In a recent case it has been held that profits from letting unfurnished property cannot be brought into taxation except under Schedule A, and the same principle would apply to losses. Schedule A contains no provision for giving relief in such a case as this.

THE ETERNAL COLD QUESTION.

"TIMOCLES" writes from Australia: There is just a chance that "H. H.," who complains of great liability to catch colds during the winter (January 18th, p. 133), may owe part of his trouble to hypersensitiveness to some dust. For some years I have investigated and treated large numbers of patients suffering from asthma, hay fever, and vasomotor rhinitis. In more than half of these I have been able to detect definite hypersensitiveness to some pollen, epithelium, or dust, and, as a rule, desensitization has greatly improved their symptoms. But I have been struck by the way in which many volunteer the information that since desensitization they have been free from colds, whereas many stated that before treatment the slightest draught was a menace to them. This improvement is not due to suggestion, because I never promised anything in this direction, and was, in fact, surprised to hear of it. Of course, in the case of "H. H." it is very unlikely that it is a factor, but as he says he would like to explore every hopeful avenue, I offer it for what it is worth. I would suggest testing with house dust from his own bedroom, feathers, horse hair, dog hair, cat hair, orris root, kapok, linseed, and a few likely grass pollens, especially timothy rye and plantain. It is essential to use good reagents for tests. Occasionally some particular food seems to be responsible. If any of these give definite reactions he should rigorously avoid the substance indicated and, if necessary, be desensitized. If he fails to react to any it might be worth trying tuberculin, if he reacts to Pirquet's test with old tuberculin. As a last resort I would suggest a complete change of environment, if possible. I assume, of course, that the nose has been thoroughly examined by a competent rhinologist.

LETTERS, NOTES, ETC.

TREATMENT OF MAMMARY CARCINOMA BY RADIATION.

Correction.

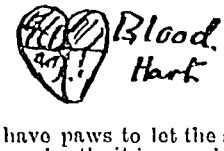
SIR G. LENTHAL CHEATLE points out an important error in his article on this subject published in our issue of May 3rd. The sixth line of the second column of page 810 should read: "is 0.5 mm. of platinum"; not, as printed, "is 5 mm. of platinum."

TESTIMONIAL TO SIR RONALD ROSS.

WE printed on February 22nd (p. 356) a list of those whose donations had been received during November, December, and January last in response to the appeal on behalf of the Ross Award Fund printed in the *British Medical Journal* of May 11th, 1929. Further contributions have been received during February, March, and April from the Penang Gazette Press, Ltd. (£654), the Railway Institute at Ebute Metta, and from Mrs. H. P. Benson, Lieut.-Colonel D. E. Crawford, W. C. Penny, T. M. Rayne, Lieut.-Colonel Temple, and F. R. Welch, amounting in all to £708 6s. 7d. The total sum subscribed, with interest, was £13,675 19s. 11d. on May 1st. Donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15.

CONFERENCE ON BIRTH CONTROL.

THE conference held on April 4th to discuss the giving of information on birth control by public health authorities passed the resolution submitted to it (*British Medical Journal*, April 19th, p. 755) in an amended form, which reads as follows: "That this conference calls upon the Minister of Health and public health authorities to recognize the desirability of making available *medical information on methods of birth control* to married people who need it."



IRRADIATED ERGOSTEROL.

DR. F. N. MOOS (Bombay), in the course of a letter on the above subject, writes: The more one reads of vitamin D the more one is convinced of the limited knowledge we still have of this "accessory food substance." It is premature, therefore, to employ a principle of doubtful utility to improve a standard natural product such as milk. If we are to accept Dr. Coward's statement that fresh milk contains hardly any vitamin D, then the logic of irradiating milk to concentrate the same active principle for use as an antirachitic measure in infants is unsound. Apart from these considerations, reports on the dangers of indiscriminate use of highly concentrated irradiated milk products cannot be overestimated. Idiosyncrasy undoubtedly plays an important part, and it is a well-known fact that a certain type of infant cannot tolerate cod-liver oil in any form. Especially during the summer months toxic and other symptoms of gastro-intestinal derangement are known to follow a minimum quantity of a vitamin D product. Every mother in the tropics knows that dermatitis, eczema, and boils result from the use of cod-liver oil. Manufacturers should arrange for clean, fresh, and wholesome food products, in quality as near as possible to that of natural food. The addition of a therapeutic or prophylactic principle for special cases should be left in the hands of the medical attendant. To sell a concentrated prophylactic or therapeutic product for general use is against all principles of dietetics. Why has the vitamin D factor long been advocated alone as a prophylactic measure? The calcium-phosphorus ratio as a determining factor in rickets has been well recognized. If the public craze goes as far as calcium-phosphorus I dare say commercial houses will soon arrange to adjust the percentage of calcium and phosphorus to meet all requirements.

"HOW MAN IS MADE."

DR. W. H. DU PRÉ (Coleford) sends us the MS. of a little essay on physiology by a boy of 10, which he thinks may be worthy of a wider public. The author heads his paper, "How Man is Made," and illustrates it with three lively anatomical drawings, one of which we reproduce below at the appropriate place.

"A man contains two eyes a Mouth and two ears, if a Dockter to feal your pulce he would cattch hold of your hand, if he wanted to tell your temperature he would put it in your mouth or under your arm. There is blood vesels all over your lungs and right at the back is the back bone, and there are bones right from your back bone to the front they are called Ribs. Some time your hart moves so it can move every where but other time it stays at the same place and goes up and down. A hart is like this:

In your hand you have paws to let the swet out of your bodey, it is best then to have a barth, it is very bad for you if all your paws are filled up, you would mostly be dead after a bit."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 46, 47, 48, 49, 52, and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *219*.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

414. Paroxysmal Ventricular Tachycardia.

M. B. STRAUSS (*Amer. Journ. Med. Sci.*, March, 1930, p. 337) records an analysis of 65 cases of paroxysmal ventricular tachycardia, 63 being collected from the literature and 2 being personal cases. This disease can only be recognized definitely by means of the electro-cardiograph, and even with this aid several criteria are necessary for diagnosis. There must be evidence that the impulses producing the tachycardia arise within the ventricles, in which case the form of Q R S complexes will be distinctly abnormal. The identification of independent auricular waves, occurring at a slower rate than the ventricular ones, points to a ventricular origin of the tachycardia. If in the interval between paroxysms the ventricular complexes are normal and there are isolated premature ventricular complexes of the same shape as those of the paroxysm, the diagnosis can be made certain. Additional evidence is obtained if the onset and termination of the tachycardia bear the same relation to the slow rate as do isolated premature systoles, and if there is a slight irregularity in the rapid rate, which is not found in other forms of paroxysmal tachycardia. Of the cases studied, 60 per cent. occurred during the fifth and sixth decades of life, and slightly over two-thirds of the patients were males. No common single etiological factor could be discovered, but 83 per cent. of the cases occurred in patients suffering from organic heart disease, and of these 60 per cent. had been treated with digitalis prior to the onset of the tachycardia. Heart failure, either of the congestive or anginal type, was present when the tachycardia was first noted in 45 cases; auricular fibrillation was present in 21, and auricular flutter in 2. The administration of quinidine, usually the sulphate, is the only measure that has proved successful in terminating ventricular tachycardia. Doses as high as 7.5 grams daily have been given, though maintenance has been possible with 0.2 gram daily. Dosage must be adjusted to the individual case, repeating the administration in increasing amounts every few hours until the paroxysm is controlled, or alarming symptoms appear. No bad effects have been recorded due to the exhibition of this drug in this condition. In the absence of organic heart disease the prognosis is good.

415. Sudden Death from Latent Diphtheria in Infants.

LESNÉ and WAITZ (*Le Nourrisson*, January, 1930, p. 32) record two illustrative cases in infants, aged 1 month and 3½ months respectively, who died suddenly without any prodromal symptom in the course of diphtheria which was detected only by bacteriological examination. They point out that the possibility of sudden death adds considerably to the gravity of any prognosis given in the case of diphtheria in young children. Of 560 children under 2 years of age admitted to Lesné's hospital in the first six months of 1929, 52 developed diphtheria, which in 27, or 9.3 per cent., was detected only by bacteriological examination (occult diphtheria). Of the 52 patients, 17 died, and 10 of these from occult diphtheria. The sudden deaths, which numbered 5, consequently represent 30 per cent. of the total mortality; 3 of the 5 deaths occurred in the course of occult diphtheria. The authors add that, in the absence of clinical signs of diphtheria, considerable care should be taken in applying the term "carrier" to an infant in whose throat diphtheria bacilli are found. When diphtheria bacilli are found in an infant's nasopharynx in association with any symptoms affecting the respiratory tract or general condition, antitoxin should be given, and the improvement in the condition will show the active part played by the diphtheria bacilli.

416. The Electro-cardiogram in Coronary Disease.

M. H. NATHANSON (*Amer. Heart Journ.*, February, 1930, p. 257) has analysed the electro-cardiographic findings in 60 patients with coronary disease. The diagnosis in these cases rested upon post-mortem findings, or upon a characteristic clinical picture, and the analysis was limited to those cases in which significant electro-cardiographic changes were observed. The most frequent abnormality was inversion of the T wave, this being found in 88 per cent. of cases. The Q R S portion of the ventricular complex was widened and notched in 13 per cent. That extensive fibrosis is the most likely pathological condition to cause permanent interference with intraventricular conduction, and that such fibrosis is nearly always due to coronary sclerosis, are facts in accord with this finding. Minor notching of Q R S occurring in Leads I and II was found to be frequently indicative of myocardial damage. Low voltage electro-cardiograms were recorded in 15 per cent. of cases, as against 0.3 per cent. among general medical material. In the few instances where there was prolongation of the P R interval, bundle-branch block coexisted. In 18 per cent. of cases extrasystoles were observed, while auricular fibrillation was recorded in only 6.6 per cent., signs of congestive failure always accompanying this irregularity. Definite or slight left ventricular preponderance was frequent (60 per cent.), this being in keeping with the common association between coronary sclerosis and hypertension. Only two patients showed slight right ventricular preponderance. The author concludes that myocardial disease is indicated by the presence of T-wave inversion in significant leads and by widened notched Q R S complexes with bundle-branch or arborization block. Other conditions which may cause T-wave inversion and which must be excluded are aortic valvular disease, hypertension with left-sided enlargement, post-diphtheric heart, and myxoedema heart. The lesser electro-cardiographic abnormalities, such as minor notching, depression of the T wave, and low voltage, are suggestive, though not pathognomonic, of coronary sclerosis.

417. Alcoholism and Nervous Diseases.

J. HAGELSTAM (*Nordisk Medicinsk Tidskrift*, March 1st, 1930, p. 122) publishes statistics and clinical records of isolated cases to show the effect of prohibition and all its consequences on the health of certain sections of the community. Total prohibition was introduced in Finland in June, 1919, and the following ten-year period, during which total prohibition was officially maintained, is compared with the previous ten-year period, 1908-18, by Professor Hagelstam, whose figures deal with the Maria Hospital in Helsingfors, of the medical department of which he was the chief until July 1st, 1927. In the first decade, during which the yearly admissions rose from 1,400 to about 2,000, the proportion of cases of alcoholism did not exceed 1 per cent. In the second decade the proportion of these cases rose from 6 (0.5 per cent.) in 1922 to 66 (3.3 per cent.) in 1928. The cases of acute ethyl alcohol poisoning were relatively rare; in the six year period 1913-19 there were 15 cases of acute ethyl alcohol poisoning, and as many as 41 cases of poisoning with methyl alcohol or denatured spirits, 16 of these cases terminating fatally. Not infrequently the first outbreak of delirium occurred in hospital in patients who had been admitted for some other manifestation of chronic alcoholism, such as epilepsy or polyneuritis. During the six-year period 1923-28 there were as many as 35 cases of alcoholic polyneuritis admitted, whereas in earlier years the few and isolated cases of polyneuritis seen could in most cases be traced to some infectious origin. Among the 2,200 patients admitted in 1923 there were 92, or about 4 per cent., in whom excessive abuse of alcohol was noted as a cause of disease. Among these patients there were 23 with more or less severe disturbances of the nervous system (neuritis in 7 cases, epileptic convulsions in 9, and delirium in 7).

418. A Possible Factor in the Incidence of Post-vaccinal Encephalitis.

O. REISCH (*Wien. klin. Woch.*, January 23rd, 1930, p. 103) reports two fatal cases of encephalo-myelitis, verified at necropsy, which occurred after vaccination in a series of 233 persons, mostly between the ages of 5 and 10, vaccinated for the first time in October-November, 1929, and all living in the same Tyrolese valley. At the same time six other children were taken ill six to twelve days after vaccination, with severe local reaction and general symptoms, headache, vomiting, pyrexia, and occasionally delirium; all these also had irregular twitching of muscles of various parts of the trunk and extremities, generally involving small or large muscle bundles rather than whole muscles. These myoclonic contractions were particularly evident in the abdominal wall. The facial muscles were little affected and the contractions did not interfere with voluntary movements; further neurological examination in these cases was negative. Examination of about 300 other healthy children, unvaccinated and vaccinated recently or some years previously, all living in the same district, showed that similar myoclonic contractions were present in a large proportion, the percentages among the vaccinated and unvaccinated being about the same. The myoclonic contractions sometimes continued for days or weeks, were generally not associated with other symptoms, and subsided without treatment. They were

differentiated from mild or subsiding chorea by the fact that in the latter the facial muscles and distal parts of the limbs are more frequently affected, and the contractions tend to involve whole muscles rather than fasciculi. Reisch suggests that the occurrence in his district of a large number of cases with irregular myoclonic contractions and no other symptoms may possibly be due to a mild widespread epidemic affection of the central nervous system, and that the two fatal cases and six comparatively severe cases of involvement of the central nervous system which occurred almost simultaneously in the same comparatively isolated community may be due to an exacerbation produced by vaccination. He urges that further investigations of possible epidemic myoclonic conditions, as well as neurological examinations of series of vaccinated persons elsewhere, should be undertaken, in order to test this factor in the etiology of post-vaccinal myelo-encephalitis.

419. Dyspnoea in Influenza.

J. LEVESQUE (*Bull. Méd.*, February 15th, 1930, p. 109) records two illustrative cases in hitherto healthy children, aged 3 years and 12 months respectively, who were suddenly attacked by severe dyspnoea; the voice was only slightly affected, and the cough was somewhat hoarse. The unusual feature in these cases, which appeared at first to be examples of laryngismus stridulus, was the long persistence of the dyspnoea, resembling diphtheria; this disease, however, was excluded by laryngoscopic and bacteriological examination. Treatment in such cases consists in the administration of antispasmodics, preferably gardenal, in doses of 3 to 5 cg. below the age of 1 year, and 5 to 8 cg. above that age, three or four times a day, the application of mustard plasters or hot compresses to the neck, and a steam tent.

Surgery.

420. Late Post-traumatic Lumbago.

ACCORDING to F. ODY (*Rev. Méd. de la Suisse Romande*, February 25th, 1930, p. 79) there is, in addition to traumatic lumbago due to muscular laceration, articular subluxation, and bony lesion of the vertebral column, also a group termed "accidental lumbago," attributable to changes in the nerve trunks at their exit from within the spinal canal. The syndrome "lumbago" is confused then with the neuralgic syndrome of "neurodochitis"—an infective or traumatic inflammation of a rigid bony canal giving passage to a nerve which is compressed by inflammatory infiltration or strangulation. In the lumbar region the articular groove may be better termed an articular canal, by reason of the thickness of the vertebral pedicles. The fifth lumbar articular groove has attracted special attention because of the compression it may undergo in the course of sacralization of the fifth lumbar vertebra. The nerve trunk lying in the articular groove is surrounded by fatty tissue, and is liable to inflammatory sclerosis. Ody cites the case of a lad, aged 19, who had suffered from lumbar pain for several years; it had been latterly diagnosed as Pott's disease. The lumbar vertebrae were immobilized in plaster for five months without any improvement. When 9 years old the patient had slipped when pulling a loaded sleigh, which passed over his lumbar region. He suffered very severe pain but continued at work until night, when his legs became so weak that he could not stand. The pain appeared to increase after immobilization, and radiated over the right side from the axillary line to the buttock. The reflexes were normal and there were no motor or trophic changes, but there was hyperaesthesia from the middle line between the first and fourth lumbar spines down to the mid-gluteal region. A skiagram showed lumbar scoliosis with angulation due to collapse of the body of the second lumbar vertebra on the right side and definite diminution of the space between this vertebra and the third. The bony outlines were obliterated by an osteophytic outgrowth forming a bridge on the right side between the two lumbar vertebrae. Lipiodol injections revealed an impassable obstacle in the epidural space, but the subarachnoid space was free. Laminectomy of the first three lumbar vertebrae was performed: the epidural fat was found to be sclerosed and very adherent to the subjacent dura, which projected slightly into the wound. The articular apophyses of the second and third lumbar vertebrae were then resected, and similar dense sclerosed fatty tissue was found to be filling the articular groove, compressing the nerve trunk, from which it was dissected with difficulty down to the transverse process of the third lumbar vertebra, where the fatty tissue appeared to be normal. The corresponding posterior root ganglion was partially removed for examination, and the wound was closed. The ganglion cells showed degenerative changes with evidence of scar formation in the surrounding tissue. The hyperaesthesia and pain disappeared immediately after the operation, and the patient left hospital in four weeks; all the vertebral movements were then free and painless, and there was no paresis of the thigh muscles. Ody remarks that Sherrington has shown that at least three spinal nerve roots must be divided before complete cutaneous anaesthesia occurs in a given area. In the case reported severe pain and disability occurred from compression of one nerve root.

421. Epigastric Hernias associated with Gastric Lesions.

F. PAPIN (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, February 20th, 1930, p. 131) describes three cases in which operation for epigastric hernia failed to give relief, because another lesion had been overlooked. These hernias are often accompanied by severe gastric disturbances, of which the etiology is obscure. In the first case a very obese woman, aged 49, had a small epigastric hernia, and had suffered for two years from colic without any vomiting. The hernial sac contained omentum. Healing was uneventful, but the pain persisted; skiagrams showed no abnormality except that the transverse colon was fixed near the greater curvature in the form of an inverted V, and it was thought that there might be a lesion of the colon or mesocolon. A second laparotomy revealed an adhesion of the old scar to the middle of the transverse colon, which was quite normal; further exploration revealed a typical callous ulcer as large as a five-franc piece at the lesser curvature. A man, aged 52, had a successful operation for epigastric hernia, but without relief of the pain, which continued and became associated with vomiting and progressive emaciation. Laparotomy showed a large tumour, which was removed easily, and proved to be an epithelioma. Pyloro-gastrectomy was performed, followed by Billroth's gastro-jejunal anastomosis; the patient remained well for four years, but now shows signs of recurrence. A man, aged 57, was operated on for an epigastric hernia which had existed since childhood, but the symptoms were not relieved. The passage of a duodenal tube while fasting gave vent to a fluid containing fragments of undigested food, and skiagrams showed a very definite deformity of the pyloric antrum. At the operation a large cylindrical epithelioma was found. Papin insists upon the necessity of skiagraphic examination, followed, if necessary, by an exploratory laparotomy, before undertaking the radical cure of epigastric hernias. In 1921 Mandl recorded forty cases of operation for epigastric hernia, among which were fifteen cases of gastric or duodenal ulcer. Chemical analysis showed hyperacidity in one case only. Skiagrams indicated a lesion in the majority of cases, but in two patients exploratory laparotomy was necessary to establish the diagnosis.

422. Pneumatosis Cystoides Intestinalis.

A. BURHANEDDIN (*Zentralbl. f. Chir.*, March 15th, 1930, p. 647), who records an illustrative case, remarks that pneumatosis cystoides intestinalis is a fairly rare disease, as he has been able to find only about 100 cases on record. The etiology has not yet been satisfactorily explained; three theories have been suggested—namely, a mechanical, a bacterial, and a clinical—but none of them have thrown full light on the essence of the disease. Burhaneddin's case was that of a man, aged 35, suffering from an extreme degree of pyloric stenosis secondary to gastric ulcer, atrophy of the liver, ascites, and dilatation of the whole portal system. On laparotomy numerous gaseous cysts were found extending along 3 metres of the intestine. Resection of the stomach (Billroth II) was performed, and recovery followed. The dilatation of the veins of the portal system and the hepatic atrophy and ascites indicate that the pneumatosis cystoides in this case was of mechanical origin.

423. The Hour of Death after Operations.

S. FREY (*Forsch. und Fortschr.*, March 20th, 1930, p. 124) investigated the time of death after operation in 500 cases which had occurred in recent years at the Königsberg Surgical Clinic. The series contained only those cases in which there was an interval of at least twenty-four hours between the operation and death, and consisted of persons of all ages and both sexes. He found that 185 of the total 500 deaths occurred in the day between 6 a.m. and 6 p.m., and 315 in the night between 6 p.m. and 6 a.m.; 158 of the latter group of patients died between 6 p.m. and midnight, and 157 between midnight and 6 a.m. The highest mortality (7 per cent.) was between 11 p.m. and midnight, and the lowest (1.6 per cent.) between 2 p.m. and 3 p.m. The mortality, therefore, in the evening, night, and early morning was decidedly higher than that during the day, the highest death rates occurring in the hours just before and just after midnight. This higher mortality admits of two explanations. The first is that the rest period in which the activity of the

organs and intensity of the vital processes are decidedly diminished occurs during the night; it is therefore conceivable that the association of the natural remission of the systemic functions imposed upon the functional disturbance caused by the disease and the operation is responsible for death. A more likely explanation, however, is that the sick person is unable to obtain this period of rest, since an increased demand is being made upon him, and that the loss of this rest period is the cause of death occurring in the night or early morning.

424. Acute Pancreatitis.

R. COLP (*Annals of Surgery*, March, 1930, p. 392), who describes acute pancreatitis as a severe abdominal catastrophe which is attended with a grave prognosis, analyses 54 cases, of which 3 were secondary to operation. Of the 51 cases, 85 per cent. presented pathological evidence of cholecystitis or cholelithiasis; at the operation the gall-bladder was found to contain stones in 28 cases, was enlarged in 9, and thickened in 4. Symptoms of gall-bladder disease were recorded in 50 per cent. of cases, with typical attacks of right upper abdominal pain, sometimes radiating to the shoulder, and accompanied by nausea and vomiting. The pain in acute pancreatitis was always intense, the average patient being desperately ill and in advanced shock, while four cases were in apparent collapse. Diagnosis is difficult owing to the variable symptoms and conditions found, and in most cases must be made by exclusion, though an abdominal puncture and aspiration of the typical oily beef juice exudate may be useful in suspected cases. Treatment must be surgical and should aim at the removal of the toxic protein products, to relieve pancreatic tension and lessen glandular necrosis; a cholecystostomy is usually indicated, and the 17 cases in which it was done showed the lowest mortality of 35 per cent. The prognosis is grave; of 46 operated cases, 23 survived, 17 making an uneventful recovery. Necropsy in 17 cases showed that death was due to the actual destruction of the pancreas, 16 dying from pancreatic necrosis. In 6 cases the entire pancreas had completely sloughed, and was lying in an abscess cavity.

425. Intestinal Polyposis.

J. GOTTESMAN and D. PERLA (*Amer. Journ. Med. Sci.*, March, 1930, p. 370) report two cases of multiple polyposis of the intestine, and comment on the etiology of this condition, which they conclude is attributable to long-standing chronic irritation. Their first patient was found to have multiple fibromatous polyposis associated with intestinal tuberculosis; in the second case there was a long history of chronic ulcerative colitis preceding the appearance of polyposis, some of the growths showing signs of early malignancy. The authors remark that it has been estimated that about 40 to 50 per cent. of intestinal adenomata become malignant; the view is held by some that in each case of intestinal carcinoma there has been previously a benign tumour.

Therapeutics.

426. Choline Hydrochlorate in Tuberculosis.

F. LEUBET and G. PERY (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, March 10th, 1930, p. 187) state that all cases of progressive tuberculosis with a low general condition and without spontaneous tendency to improvement show a marked decrease in the blood cholesterol and sometimes also in the blood sugar, a disequilibrium which is evidence of a deep humoral trouble. In support of this statement the blood sugar and chol sterol estimations in 65 cases are given. As a result of these observations the authors have employed choline in the treatment of tuberculosis, and claim to have obtained most favourable results in all forms of the disease, even in advanced cases. The treatment is unattended with danger in the doses prescribed, and the results are better the earlier it is instituted. Of 25 cases, 17 of which are recorded, clinical cure resulted in 7, and even in the fatal cases (some with intercurrent affections) a manifest improvement, which lasted for the duration of the treatment, was noted. Following administration of the drug there is a lowering of the temperature (in the majority of cases to normal), a return of the appetite and sleep with a re-establishment of the digestive functions, a noticeable disappearance of constipation, a rapid gain in weight, and a subjective sense of euphoria. The blood cholesterol is greatly increased, and the blood sugar-cholesterol ratio returns to normal. The authors employ subcutaneous injections of 2 cg. of choline hydrochlorate in 1 c.cm. of distilled water every two days without any discontinuance, even during menstruation in females, on which it has no effect. The importance of *continuous* treatment is emphasized. As an adjuvant, cachets each containing 1 gram of pure cholesterin are given daily with the meals (or a parenteral injection of an oily solution twice a week), or 1.5 grams of glycerophosphate of lime, or lecithin daily; of these the lime salt is to be preferred. Symptomatic treatment is reduced as much as possible, but rest and climatic and dietetic therapy are employed.

427. Lysed Typhoid Vaccines.

J. CARONIA (*Amer. Journ. Dis. Child.*, January, 1930, p. 1) claims that, in addition to over 1,000 recorded cases, several thousand cases of typhoid fever have been successfully treated in different parts of Italy, within the last ten years, by means of lysed vaccines. To a culture in a liquid medium of various strains of Eberth's bacillus, a 2 to 3 per cent. volume of typhoid convalescent blood is added. The culture is then incubated at 37° C. until complete or nearly complete lysis of the bacteria is obtained. The clear portion of the liquid is separated from the sediment, carbolized, and used as vaccine. For intravenous injection the dose is 0.5 to 1 c.cm., and for intramuscular or subcutaneous injection 1 to 3 c.cm. The dose is progressively increased and is given every alternate day, or every third day up to the appearance of defervescence. Caronia states that intravenous injections frequently cause resolution by crisis, while lysis generally follows subcutaneous or intramuscular injections. In almost all cases the lysed vaccine prevents a fatal outcome; the average duration of the disease is shortened from 30 to 40 days to 15 to 20 days; the number and severity of complications are reduced and recurrences are fewer; and no new risks are entailed by the employment of the vaccine. A small proportion of failures are reported. Caronia suggests that the action of the lysed vaccine is a rapid desensitization of the body tissues to the protein of Eberth's bacillus, analogous to the slower process of natural healing.

428. Treatment of Leprosy.

R. G. CROSBIE (*Brit. Journ. Derm. and Syph.*, March, 1930, p. 125) reviews the present methods of treatment in leprosy in the hope of clearing up some of the confusion that has arisen and of laying down general guiding principles. Since nerve tissue is most susceptible to the invasion of the *Mycobacterium lepræ*, and skin manifestations do not occur till later, the importance of deciding what constitutes an early nerve case is obvious. These present isolated hypopigmented patches associated with loss of light touch sensation along the cutaneous distribution of one or more of the important nerves, such as the ulnar or peroneal. A few macules or erythematous patches, without any nodule formation, constitute an early skin case, but when once there is nodule formation the case falls into the category of late skin leprosy, while the presence of perforating ulcers, claw-hand, facial paralysis, and loss of pressure sense constitute late nerve leprosy. The most uniformly good results follow the injection of hydnocarpus oil and 4 per cent. creo-ote, or "alepol," or the ethyl esters of hydnocarpus oil. Potassium iodide, in gradually increasing doses until 240 grains are reached, and diminished or withheld according to the severity of the reaction, is beneficial in strong healthy adults with but few bacilli demonstrable; it must be cautiously used, since it is one of the most powerful drugs available for producing a reaction. Protein shock resulting from the injection of 5 c.cm. of milk intramuscularly, or of T.A.B. intravenously, has been used extensively of late, and, judiciously applied, may cause rapid subsidence of the leprotic infection. No one drug has precedence as regards value, but the author considers that modern therapeutics can effect a cure in early cases and bring the late infective cases to a stage of non-infectivity.

429. Complications Provoked by Thyroid Medication.

S. A. HOLBØLL (*Ugeskrift for Læger*, January 30th, 1930, p. 109) remarks that even though the introduction of physiologically standardized thyroid preparations, and the frequent control of their effects by measurements of the basal metabolism, have reduced the number of cases of hyperthyroidism following thyroid medication, it still not infrequently provokes disturbing signs and symptoms. He tried to determine the frequency of these phenomena, and to ascertain if they included processes which could be accurately measured. Of the 30 patients treated for adiposity, 7 were men and 23 were women. Their ages ranged from 22 to 50 years, most of them being between 30 and 45. They were for the most part from 30 to 50 per cent. over-weight; in no instance was there any definite endocrine abnormality, and cases of myxoedema, diabetes, ovariectomy, hyperplesia, and anaemia were excluded. The fasting diet on which these patients were kept represented 1,200 calories; while 25 of the 30 were given thyroid extracts, the remaining 5 were treated by dieting alone, and thus served as controls. In 10 (8 women and 2 men) of the 25 cases symptoms of thyroid poisoning appeared

towards the end of the third or fourth week; they included tremor, palpitation, nervousness, and increased perspiration. The thyroid medication was discontinued, and in every case all the symptoms disappeared after two to three weeks. All the patients lost weight; but while the average loss of weight of the 5 controls was only 5.4 kilos, that of the thyroid-treated patients was 10 kilos. The pulse rate of the 5 controls remained unchanged or became slower, but it rose in all the cases treated with thyroid, the average increase being 24.5 beats per minute. In the 10 cases of hyperthyroidism this rise was 33 per minute; in the remaining 15 cases it was only 18.8. While the blood pressure remained unchanged or fell a little in the 5 controls, it rose in 9 of the thyroid-treated patients, 4 of whom also showed a marked fall of haemoglobin in the blood. The rate of sedimentation of the blood cells was unchanged in the 5 controls, but it was hastened to a pathological degree in 10 of the 25 thyroid-treated patients, who showed other well-known manifestations of thyroid poisoning. Holböll concludes that by watching the rate of sedimentation during treatment with thyroid extracts, it is possible to ascertain early whether they are well tolerated or not; for if the rate of sedimentation increases during such treatment, there is a very considerable likelihood of the patient developing signs of hyperthyroidism sooner or later. On the other hand, when the rate of sedimentation remains normal, it may be assumed that the dose of thyroid extract is not too big.

430. Measles Prophylaxis by Adults' Serum.

J. D. VAN CLEVE (*Arch. of Ped.*, February, 1930, p. 124), as the result of the study of the literature and his own observations, comes to the following conclusions. Immune measles goat serum or antistreptococcus measles antitoxin is the best to use because it can readily be obtained in large quantities and be standardized. Convalescent serum is equally good, but is not so easily procurable, and there is always the possibility of injecting tuberculous or syphilitic serum. The serum of adults who have had measles in childhood is not so efficacious, but, where other kinds are not available, is of value for protecting young and ill-nourished children, and for modifying the disease in older patients without the risk of complications. In the case of children under the age of 4, especially those who are rickety, tuberculous, or delicate, a relatively large dose (15 c.cm.) should be given. In older children and adults a smaller dose may be given, sufficient to modify the disease, since serum protects only for four to six weeks, while the modified cases have a lasting immunity.

Laryngology and Otology.

431. Staphylococcal Laryngitis.

R. Y. MATHEW (*Med. Journ. of Australia*, January 11th, 1930, p. 34) records four cases, in children aged from 15 months to 4 years, of staphylococcal laryngitis simulating laryngeal diphtheria. Tracheotomy was performed in each case, but only one recovered. The evidence against diphtheria was the absence of response to diphtheria antitoxin and the absence of membrane in the trachea. Moreover, the higher temperature, the repeated failures to find *B. diphtheriae* in cultures from the throats and tracheotomy tube, the repeated findings of *Staphylococcus aureus* in cultures, and the growth of the organism from a patch of broncho-pneumonia and pericardial fluid after death, supported the view that the condition was a primary infection of the larynx with highly virulent staphylococci.

432. Treatment of Acute Mastoiditis.

G. O. CUMMINGS (*Med. Journ. and Record*, March 19th, 1930, p. 306) discusses the symptomatology of acute mastoiditis and the question when operation is necessary. Mastoiditis is practically always secondary to middle-ear disease, and very rarely follows trauma or a direct infection from the blood stream. Anatomically three varieties of bone have been found at operation: the cellular or usual type; the diploic or non-pneumatized, which is rather rare; and the sclerotic, which results from the new bone formation caused by chronic mastoiditis. Pathologically also three types are found: the coalescent (the usual), in which a breaking down of intracellular walls with the formation of pus and granulation tissue occurs: the haemorrhagic, wherein there is intense inflammation of the intracellular walls with but little tendency to the formation of pus or granulation tissue; and the chronic or sclerotic type. Clinically the coalescent type is the most frequent and produces the greatest variety of symptoms. Among these, tenderness on pressure over the mastoid is the most important finding. Persisting tenderness over the tip after prolonged treatment indicates operative intervention. Occasionally in infants swelling and redness may occur over the mastoid, and may disappear under medical treatment; in older children and adults it practically always indicates the necessity for operation. The ear drum usually presents no diagnostic characteristics; the nature and amount of the discharge are of greater value. Much discharge suggests extensive necrosis of the mastoid and the need for surgery. Bacteriological and *x*-ray examinations give definite information. Infrequently signs of meningeal irritation (termed meningismus in contrast to meningitis) occur and demand immediate operation. All acute ear infections with temperature, pain, and mastoid tenderness do not demand operation, and other measures may suffice. The principal object of a mastoidectomy is to save life, and an operation should not be advised unless it is deemed safer to operate than to refrain. Operation should be postponed for four or seven days after the onset of mastoid symptoms, unless the mastoiditis is of a fulminating type. This delay gives an opportunity to determine whether the disease will yield to conservative measures, and it allows the tissues (mastoid) to build up a certain resistance to infection, when the operation can be more safely performed. Seven hypothetical cases are described to illustrate the proper course to be adopted in various conditions.

433. Otogenic Reflex Cough.

A. PAGANO (*Arch. Ital. di Otol., Rinol. e Laryngol.*, December, 1929, p. 736) states that reflex cough arising from the ear is fairly frequent, as is shown by the fact that Fox noted it in 15 out of 86 patients. Guder examined 111 men and 89 women, with the following results. In the men he produced a cough by stimulation of the left ear in 12, of the right ear in 11, and of both ears in 4; while in women the cough was produced by stimulation of the left ear in 5, the right in 8, and both ears in 2. Reflex cough was found to be most frequent between the ages of 10 and 20, being met with only once before 10 and twice after 60. Pagano carried out observations on 200 subjects, 105 of whom were males and 95 females; 60 were perfectly healthy, while 140 had various diseases of the ear and upper respiratory tract. The ages of the patients ranged from 6 to 71 years. Stimulation of the external auditory meatus by the introduction of a probe gave rise to a cough in 43 cases, 24 of whom were females and 19 males: in 16 by stimulation of the right ear, in 19 of the left, and in 8 of both ears. Stimulation of the tympanic membrane with a probe produced a cough in 3 healthy subjects, and in 16 suffering from diseases of the ear and upper respiratory tract. Pagano concludes that otogenic cough is found in about 21 per cent. of all cases, being somewhat more frequent in females than in males. The presence of lesions in the upper respiratory tract is not necessary for the production of the cough, although they favour its occurrence. The patient's state of nervous excitability may have a certain importance in the production of the cough. Stimulation of the tympanic membrane produced a cough in only 9.5 per cent.

Obstetrics and Gynaecology.

434. The Times of Ovulation and Conception.

FROM observations at laparotomy in 118 patients, in about one-third of whom menstruation was irregular and in the remaining two-thirds of whom the menstrual cycle was regular and of twenty-three to forty-five days, K. OGINO (*Zentralbl. f. Gynäk.*, February 22nd, 1930, p. 464) concludes that ovulation takes place during the five days' period which extends from the sixteenth to the twelfth day before the expected date of commencement of menstruation. This rule is not affected by irregularity of the menstrual cycle in the individual, or its variation in duration from patient to patient. Apparent exceptions to the rule are due either to (1) severe endometrial disease, in which the uterine mucosa is refractory to the action of the corpus luteum hormone, or to (2) destruction of the developing corpus luteum from mechanical injury or as a result of disease—a premature menstruation follows. Ogino believes that the differing opinions which have been put forward concerning the time of ovulation are due to reckoning from the beginning of the last rather than the expected beginning of the next menstruation. The time of fruitful coitus is as a rule from the nineteenth to twelfth days before an expected menstruation; this comprises three days before the ovulation time and the five days of the latter. After the eleventh day preceding menstruation conception is impossible; during the period between the twenty-fourth and twentieth days preceding menstruation, coitus, owing to the comparatively short period of survival of the human ovum, is only fruitful in exceptional cases. In correspondence with these views, cases are mentioned in which there has been coitus before or during the ovulation period,

thus reckoned, and pregnancy has followed without an intervening menstruation; pregnancy without post-nuptial menstruation does not occur if coitus takes place during the days of the menstrual cycle which follow ovulation.

435. Contraindications to Radiotherapy in Pelvic Tumours.

J. L. FAURE (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, January, 1930, p. 43) records two cases in which cystic or papillary epithelial tumours of the ovary increased in size after radiotherapy. A 2-para, aged 45, complained of profuse menstruation; a fibroid was suspected, and radiotherapy was ordered. The first application was followed by increase in size of the abdomen; the second by fatigue, further increase in size, and a suspicion of ascites; while after the third treatment the abdominal swelling was so marked and ascites so evident that the abdomen was opened. A uterine fibroid was found, flanked on either side by an ovarian tumour, partly cystic and partly papillary. The uterus and both lots of appendages were removed. In the second patient an abdominal tumour, thought to be a uterine fibroid, increased in size despite radiotherapy. The abdomen was opened and a left papillary ovarian tumour, adherent to the uterus and broad ligament, was discovered and removed. There was spread of the growth to the right side, and the patient died some months later. Faure mentions two other cases similarly treated without benefit, and concludes that in certain cases where the diseased cells are not destroyed they are stimulated; in certain cases benign epithelial ovarian tumours may become malignant. He advises strongly against the radiotherapy of pelvic tumours unless it is absolutely certain that the tumour is a fibroid growth of the uterus uncomplicated by the presence of an ovarian tumour.

436. Late Effects of Eclampsia.

K. KOHDS (*Zentralbl. f. Gynäk.*, March 15th, 1930, p. 666) analyses the after-history of 32 eclamptic patients in whom, three to eighty-five months after discharge from hospital, the blood pressure and the fundus oculi were examined, and the renal function was investigated by diuresis, urea concentration, and other tests. At the time of discharge none had abnormally high blood pressure, but one half had small amounts or traces of albumin in the urine. The re-examinations showed that in no case were signs of chronic nephritis present, as indicated by increase in the non-protein blood nitrogen, high blood pressure, cardiac hypertrophy, and haematuria. Nineteen patients, however, showed some cardio-renal abnormality, and, after deduction of cases of comparatively recent eclampsia in which future improvement was possible, 8 showed signs of degenerative chronic nephrosis. Of the 10 patients in whom the history pointed to nephropathic conditions preceding their eclampsia, 9 showed morbid renal conditions at re-examination. More than one-half of the patients reported severe headache, faintings, excitability, timidity, and/or loss of memory—a finding which is similar to that of Nevermann, who inferred that slight organic cerebral changes often follow eclampsia. A similar "follow-up" of 19 cases of pre-eclampsia showed that 14 had albuminuria, a pathological urinary sediment, hyperpiesia, and impaired renal function—alone or in combination. In all these cases morbid renal conditions appeared to have antedated the pre-eclamptic pregnancy toxicosis. Three of these patients were found to have chronic nephritis. The general conclusion is drawn that pregnancy brings considerable danger to the kidneys of those who have already had kidney trouble, and that such subjects should be much more carefully supervised during pregnancy than is commonly the case.

437. Volvulus of the Healthy Adnexa.

THOUGH for a number of years volvulus of the healthy adnexa has been considered a very rare event, L. MICHON (*Gynécol. et Obstét.*, February, 1930, p. 103) believes that it occurs more frequently than is thought, and reports five cases of this condition. A distinction must be made between torsion of the entire adnexa and that of the tube alone. In most cases the tube only is twisted on the mesosalpinx, the ovary lying outside the torsion and being absolutely healthy. In other cases the entire adnexa are involved, and both the tube and ovary are included in the volvulus. Much rarer are cases of torsion of the ovary alone. The most frequent site of the torsion is at the uterine insertion of the tube, but one or more centimetres of the organ may be free and the volvulus be situated at its middle portion. The torsion is usually very marked—three or four turns of a spiral—and is rarely less than 360 degrees. The affected organ is very often greatly increased in volume; in one of the present cases the piece removed weighed 420 grams. The tube, as a rule, contains coagulated blood, which sometimes forms a veritable infarct. Often the termination of the oviduct cannot be seen, being obscured by adhesions, but sometimes it is clearly visible. The volvulus may be accompanied by an effusion of blood, but this rarely forms a true haematocele. The condition of the opposite adnexa should be noted; these are generally perfectly healthy, though the tube may be abnormally long and attached to an equally long meso-salpinx. The diagnosis that the adnexa involved are healthy can be made on certain presumptions: the previous integrity of the genital apparatus (this, more common in children and virgins, can be confirmed histologically), by the volume and consistency of the uterus, and by the normal condition of the opposite adnexa. The symptoms are very variable. Some cases present an acute symptomatology, simulating appendicitis or torsion of an ovarian cyst; others are subacute; while others are more or less chronic and may be mistaken for salpingitis. As regards the etiology of this condition, Michon believes that three factors should be considered: the congenital anatomy of the adnexa, such as an abnormal length of the tube; localized adhesions; and the state of the sympathetic system of the tube. The existence of peristaltic and antiperistaltic movements in this organ is well known, and it is suggested that these torsions may be due to a physiological disorder of the peri-tubals. Operation is the only treatment, and the affected part should be removed. If the tube alone is involved the ovary should be conserved. A case is reported of tuberculosis of both tubes and torsion of the left one; double salpingectomy was performed, with subsequent cure.

438. The Zondek-Aschheim Reaction in Chorion Epithelioma.

F. SCHULTZE-RHONHOF (*Zentralbl. f. Gynäk.*, March 8th, 1930, p. 578) mentions a series of 79 cases in which the Zondek-Aschheim test was performed to clear up diagnostic difficulties when early uterine or extrauterine pregnancy was suspected: the result was fallacious in one instance only. He holds that it is essential to adhere to the original technique, using five test mice. The test was positive in two patients with hydatidiform mole, and in four suffering from chorion epithelioma; the author attaches considerable prognostic importance to the test in both diseases. Histories are recorded of patients in whom the Zondek-Aschheim test gave negative results after removal of a hydatidiform mole; of patients in whom the test remained negative and clinical findings satisfactory after the operative extirpation of a chorion epithelioma; of a woman in whom the test remained positive between operation for chorion epithelioma and death three and a half months later; and of a patient whose reaction became less well marked after x-radiation and apparent regression of a metastasis following operation for chorion epithelioma. Schultze-Rhonhof remarks that the intensity of the Zondek-Aschheim reaction in cases of chorion epithelioma — in which trophoblastic tissue is abundant but pregnancy absent—points to production in the placenta of the hormone concerned.

Pathology.

439. Experimental Infection and Avitaminosis C.

L. BAJ (*La Clin. degli Organi di Movimento*, January, 1930, p. 477) has investigated experimental scurvy and the changes which arise in the manifestations of the deficiency when these are complicated by infection. The experiments were made on guinea-pigs, and a condition of scurvy was produced by an exclusive diet of corn and dried cereals, a diet absolutely free from vitamin C. Adult animals of about the same weight were chosen and are considered in four groups. (1) Those on scorbutic regime and not subjected to treatment; these all died with pronounced scorbutic symptoms. (2) Animals on the scorbutic diet and injected, some subcutaneously, others intraperitoneally, with *Staphylococcus pyogenes albus*; these showed on post-mortem examination not any or only slight symptoms of scurvy. (3) Animals on a normal diet and infected with *Staphylococcus pyogenes*; these all died with severe pyaemia. (4) Animals on the scurvy diet, with marked scorbutic symptoms, and later receiving staphylococcal infection: these showed aggravated symptoms, and death was hastened; there was no evidence of any retrogression of the scorbutic condition. The serum of the scorbutic animals was found to have a slightly raised calcium and phosphorus content. The author finds that in experimental scurvy from avitaminosis C the most constant and evident symptoms are those affecting the bones. In animals on a scorbutic diet and infected with the staphylococcus the phenomena of suppuration are dominant and the changes in the bones are less important, but the infection does not arrest the scorbutic condition, and the infection of these animals is of a more severe type than in animals under ordinary diet. The absence or less degree of avitaminotic

symptoms in the animals infected with staphylococcus may be due to the formation by the micro-organism of a substance possessing antiscorbutic properties.

440. Separation of Typhoid from Dysentery Bacilli by Motility.

J. SCHUBERT (*Zentralbl. f. Bakt.*, March 4th, 1930, p. 18) describes a method for the rapid separation of typhoid from dysentery bacilli by making use of the property of motility. The principle of the method is to inoculate a tube of semi-solid medium with the organism to be tested, and follow the rate of growth down the tube; the motile typhoid bacilli grow rapidly down through the medium, whereas the non-motile dysentery bacilli grow only on the surface. To follow the rate of growth downwards it is advisable to incorporate in the medium a fermentable sugar, and a suitable indicator to detect the formation of acid. The medium that the author recommends consists of a mixture of five parts of nutrient agar, containing 0.3 to 0.4 per cent. agar, and one part of 15 per cent. nutrient gelatin; 2.5 per cent. of glucose is added, and the reaction brought with soda to *p*H 7.4 to 7.6. The medium is coloured with watery blue, 1 c.cm. of a 1 per cent. aqueous solution being added to every 100 c.cm. Test-tubes are filled so as to contain a column of medium 10 to 12 cm. in height. Inoculation is made by pushing the charged platinum loop half-way into the surface of the medium. Incubation is performed at 37° C. After eighteen hours tubes inoculated with the typhoid bacillus are coloured blue for about 5 cm. from the surface; those inoculated with the paratyphoid bacilli are coloured the whole way; while those inoculated with dysentery bacilli show merely a surface coloration.

441. Effects of Vitamin A Insufficiency.

R. MCCARRISON (*Indian Journ. Med. Research*, January, 1930, p. 693) records certain observations with regard to the effects of insufficiency of vitamin A, in association with other food faults, on the thyroid gland and mucous membrane of the respiratory tract. Experiments were carried out on 23 rats, which were fed for twelve months on a diet chiefly lacking in vitamin A, but also in vitamins C and D and in certain mineral elements. The manganese content was relatively high. The iodine content was not determined, but, as the components of the diet were derived from an iodine-rich soil, it was assumed that iodine was not lacking in them. After the animals were killed examinations were made of the thyroid gland and trachea. No anterior or lateral enlargement of the gland was noted, but in 5 rats a backward growth of the posterior borders had occurred so that they met behind the trachea. In 15 animals proliferative changes in the tracheal mucous membrane were seen, and abnormal distension of the follicles of the thyroid had occurred in 11 of these. Keratinization of the tracheal epithelium was occasionally observed, but the proliferative changes predominated. These appeared to be the result of a chronic protracted inflammatory reaction, in which varying numbers of mononuclear cells pervaded the subepithelial layer of the mucosa, polynuclear cells being comparatively rare. In some cases the thickening of the mucosa which was thus produced was slight, but in some the membrane was thrown into polypoid or villiform elevations which greatly reduced the lumen of the trachea. These masses closely resembled the hypertrophied, hyperplastic adenoid tissues (adenoids) so frequently found in badly nourished children. The changes in the thyroid gland consisted in distension of a large proportion of the follicles with colloid material and frequent distortion of their shape, secretory activity being present in parts of the gland not affected by follicular distension. McCarrison states that these observations may be pertinent to other problems. Among these are: the possible relation of faulty food containing an insufficiency of vitamin A to adenoids, and the possible relation of insufficiency of vitamin A to iodine metabolism and goitre-formation.

442. Carotinaemia.

R. RUMMO (*Rif. Med.*, January 20th, 1930, p. 96) regards the carotinoid pigments as the most important of the lipochromes so widely diffused throughout the vegetable kingdom and more recently recognized as occurring in milk, butter, eggs, corpus luteum, fat, and in blood serum. The higher animals cannot produce carotine synthetically, but obtain it ready made from vegetables. Carotine is an unsaturated hydrocarbon ($C_{40}H_{56}$) with a strong affinity for oxygen, being transformed into colourless xanthophyll. In pure orm it appears in small variable crystals, slightly soluble in alcohol, but most soluble in chloroform, benzol, and carbon disulphide; it gives two characteristic absorption bands in the spectrum, but is inactive to polarized light. Clinically cases of carotinaemia or hypercarotinaemia are reported in which the whole body is jaundiced, the urine a dark amber colour, the stools contain bile, and the sclerotics are untinted; the blood serum shows the pre[illegible] of an excess of carotine. The condition has been reproduced by giving a diet rich in carrot; the patients are not really ill, and the condition quickly disappears by living in the fresh air. The cutaneous coloration in some cases of pernicious anaemia, diabetes, xanthelasma, and tuberculosis is possibly due to diminished organic oxidation, whereby the carotine is not completely destroyed and accumulates in the tissues and in the blood; it is suggested that perhaps the straw pallor of cancerous patients is caused by carotine, and that the hyp[illegible] on the def[illegible] relation between carotine and vitamin A; potato and maize are equally poor in this pigment and in vitamin A, whereas bone marrow, butter, and yeast extract are equally rich in both these substances. Experimentally produced avitaminosis A (dogs and rats) can be cured by the administration of small doses of carotine.

443. Epidemiological Types of Dysentery Bacilli in Denmark.

K. BOJLÉN (*C. R. Soc. de Biologie*, February 28th, 1930, p. 613) during the years 1926 to 1929 isolated dysentery bacilli from 732 cases of dysentery in Denmark. Of the strains recovered, 537 proved to be of the Kruse E-Sonne type, 193 of the Flexner type, and 2 of the Shiga type. Schmitz's bacillus has not yet been found in Denmark. No clinical difference was noticed between infections due to Sonne's and those due to Flexner's bacillus. In order to find out whether the biochemical reactions of strains of bacilli isolated from a given epidemic were constant, as many strains as possible were collected at intervals from the same patient; and, during the course of any epidemic, strains were collected from as many patients as possible. In all, 2,216 strains were isolated. It was found possible to classify the Sonne type into four different epidemiological groups on the basis of xylose and maltose fermentation. Group A was negative to xylose and positive to maltose; Group B was negative to xylose and positive to maltose, but maltose was not fermented for three to six days; Group C was positive to xylose and to maltose; Group D was also positive to xylose and to maltose, but maltose was not fermented for three to six days. The Flexner type was divided into two main groups on the basis of sucrose fermentation. The sucrose-negative group was subdivided into five subgroups on the basis of sorbite and l-arabinose fermentation and the production of indole. The sucrose-positive group was divided into four subgroups on the same series of tests. Serologically the sucrose-positive differed from the sucrose-negative strains, and within each of these groups there were serological subgroups. The author is satisfied that the different types he describes are epidemiologically constant.

444. Chronic Lymphatic Leukaemia.

E. PRIESSNER (*Wien. klin. Woch.*, February 6th, 1930, p. 170) refers to the difficulty of fixing the type of chronic lymphatic leukaemia in those cases where there is abundant myeloid growth, myelocytes and even myeloblasts appearing in the peripheral blood; he raises the question whether these cases should be regarded as mixed myeloid and lymphatic leukaemia, or whether the myeloid element indicates the occurrence of metaplasia. In a series of typical cases of chronic lymphatic leukaemia the myeloid elements generally showed a marked nuclear shift to the left; the degree of this shift is demonstrated in a table showing the ratios of unsegmented to segmented forms, the normal ratio being about 0.1. In the first eight cases, all of which showed a marked left-handed shift, there is a lowered absolute leucocyte count, which expresses a high degree of bone-marrow activity, such as occurs in the severest septic infection; contrasting with infection leucopenia with left handed shift there is often a high eosinophil value. In the three last cases, which showed no left-handed shift, there was no leucopenia, the white cell count being about normal or slightly lowered.

445. Determination of the Coagulation Rate of the Blood.

C. FLANDIN and A. TZANCK (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 7th, 1930, p. 192) advocate the following procedure for determining the rate of coagulation of the blood. A syringe for the removal of blood is filled in the usual way and then emptied, leaving only a thin film of blood spread over the inner wall of the syringe, which is now laid upon the table; the fluid blood collects on the lower part of the tube, and by turning the syringe over the blood is moved to the opposite wall. This movement is repeated every thirty seconds until at a given moment the blood remains fixed, and the coagulation is definite. To verify this a little water is aspirated into the syringe; in place of the total haemolysis obtained with fresh blood, a clot is floated in the water. The coagulation takes place normally at the second minute. Clotting occurring within a minute and a half is abnormally accelerated; a delay of more than four minutes is certainly pathological, and if delayed beyond six minutes the blood may be regarded as incoagulable.

FORMASAL AND ARTHRITONE

By Our Analytical Experts.

No. 16.—ROBOLEINE.

HAVING heard a good deal of the virtues of Roboleine as a good "body-builder" in cases of malnutrition, we selected a sample of this food for analysis by our experts this week, as we desired to know whether it was really as good as it was reported to be. The result has proved that its makers, Oppenheimer, Son and Co., Ltd., are justified in claiming that it contains all the vitamins at present known to medical science, and that it is an excellent digestive food. The sample analysed was found to contain the following:—

	Per cent.
Moisture	23.23
Fatty matter	4.04
Mineral matter	1.72
Phosphate as P_2O_5	0.78
Nitrogen	0.66
Equal to protein (Factor 6.38) ...	0.32
Maltose	Per cent. 52.00

Lecithins and citralis were also present.

Roboleine is no new product. It has been in use for fully a generation, and proved itself valuable over and over again in cases of debility, loss of weight, malnutrition, sleeplessness, and especially so in tuberculous conditions. Nursing mothers have found both the quantity and quality of their milk improved by taking it, and for artificially fed babies it makes a useful adjunct in the diet. Full directions as to dosage are issued with each bottle, and nurses may feel quite safe in taking it themselves when feeling a little run-down, or in recommending a course of it to the convalescent patient just leaving their care. After influenza, typhoid fever, or any wasting condition, Roboleine should be taken regularly for three or four weeks while strength is returning.

The extract given shows the result of an independent analysis on a sample of ROBOLEINE purchased in the open market and made by the expert analysts advising a leading professional journal. The report shows that ROBOLEINE contains all the vitamins, and it confirms all the claims made for ROBOLEINE by the manufacturers, both as a body-builder and an anti-infective.

FOR DEAFNESS

"ARDENTE" STETHOSCOPE.

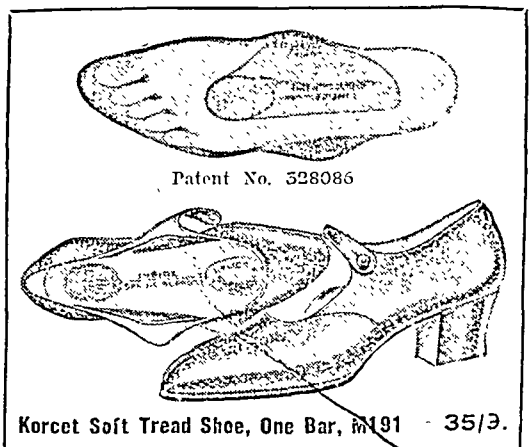
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

FREE HOME TESTS arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.



Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request

Korcet Soft Tread Shoe, One Bar, M191 35/9.

The Aching Foot

Relief for Metatarsalgia

Booklet entitled "Foot Relief" on request.

An aching foot is a factor making for nervous strain. The new KORCET Soft Tread Shoe has been specially designed to meet the objections of medical men to ordinary fashion shoes. Its construction is unique. The waist of the foot is held up by well designed lateral supports and a resilient insole spring, while the ball of the foot rests on a metatarsal pad. Correctly fitted, these shoes give the utmost measure of relief wherever there is pain or any tendency to flat-footedness.

KORCET SOFT TREAD SHOES

HUMBER

SUCH CARS AS EVEN HUMBER NEVER BUILT BEFORE

How can Keith Bradbury Ltd. sell clothes at cash prices for £1 per month?

THE ANSWER

IN providing say our first 1,000 customers with clothes upon the subscription basis, naturally we would be obliged to sink a capital sum of something like £6,000; but after this we receive a monthly income of £1,000, which automatically meets the cost of running the business.

The interest on the capital invested at 5% amounts to £300, but when this is apportioned it does not represent a per suit cost of 2/6, and even this is offset by cash discounts since a regular income enables us to pay the manufacturers cash for their cloth.

Upon the old-fashioned 'credit' cash basis of 'alleged' business, tailors doing £6 and some give 3, 12 months' credit times [illegible] results in con- which [illegible] interest siderable [illegible] dead capi- charges and [illegible] by bad tal, followed debts.

These heavy overhead expenses are not incurred by Keith Bradbury Ltd. on their monthly basis of doing business, with the result that a FREE VALET SERVICE can be provided for the care of customers' clothes after purchase.

There is nothing undignified in accepting credit from your tailor, any more than there is in arranging terms with a Bank or Building Society—and it is certainly more convenient to pay your way out of income rather than to disturb capital.

Please come and see for yourself the low-priced West End clothing which Keith Bradbury Ltd. can offer by doing business on a monthly basis at terms of from £1 per month.

An interesting catalogue and full particulars of our credit facilities gladly sent on request.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. *Milk*, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for *handicrafts*, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Tel.: 64117. *For terms etc., apply to the Medical Superintendent.*

THIS YEAR – See

CANADA

Easy to Reach
Easily Travelled

TAKE A NOVEL HOLIDAY THIS YEAR AND SEE WONDERFUL CANADA!

LAKE LOUISE

LAKE LOUISE in the Canadian Rockies, is one of the most beautiful sights in the World!
Snow-crowned peaks enclose it, where it lies 630 feet above the railway. A glacier drops into the far end, and in its glacial-green waters are seen, changing every moment, those lovely reflections that have made it the most-photographed spot on earth.
Pony trails lead away through silent, primeval forests to Lakes in the Clouds, Paradise Valley, Moraine Lake, and a score of other excursions. Swiss guides take you mountain-climbing. Smooth motor roads invite you to Banff, Yoho Valley, the Kicking Horse Trail.
And for accommodation there is the superb Chateau Lake Louise, with swimming, dancing, tennis.
Lake Louise is one of the 35 places on our "Across Canada" Tour—a seven-week trip through the Rockies to the Pacific Coast and back. Some of the other places are Quebec, Montreal, Ottawa, Toronto, Niagara, Winnipeg, Banff, Calgary, Vancouver, Victoria, Windermere Valley and Nipigon.
The Tour starts July 25th, sailing by the DUCHESS OF YORK. Special train detailed to party, kept waiting while you are sightseeing. "All in" price includes steamship, railway, and sleeping car fares, hotels, meals, drives, transfers, guide and gratuities.
And then from June 27 to August 15 we have 11 shorter tours, from 19 to 26 days, visiting some of the principal sights of Eastern Canada—some of them including New York.
Or "Go-as-you-please" holidays? We will gladly prepare itineraries, short or long.
We have just issued a beautiful little book with 32 coloured illustrations, e.g. Holidays in Canada. Shall we send you a copy of it? Ask about Booklet Tour C12.

Warwickshire and Coventry JOINT COMMITTEE FOR TUBERCULOSIS.

[illegible] SUPERINTENDENT OF THE [illegible] KING EDWARD VII [illegible] HERTFORD HILL, near WARWICK. (195 Beds.)

Applications are invited from male qualified and registered Medical Practitioners for the post of Medical Superintendent of the Warwickshire King Edward VII Memorial Sanatorium, Hertford Hill, near Warwick. The person appointed must devote the whole of his time to the duties of the office, and must have had special practical experience in the treatment of tuberculosis in sanatoria, dispensaries, and otherwise, and must be thoroughly acquainted with modern methods of diagnosis and treatment.

In addition applicants must have held the appointment of Tuberculosis Officer or Medical Superintendent with the approval of the Minister of Health, or who, subsequent to qualification:

(1) have had at least three years' experience in the practice of his profession;
(2) have spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical or surgical cases; and
(3) have received special training, for a period of not less than six months, in the diagnosis and treatment of tuberculosis.

The salary is at the rate of £800 per annum, plus unfurnished house, including fuel, light, and laundry, valued at £100 per annum, but not board. The salary will be subject to a deduction of 5 per cent. in respect of contributions under the Local Government and Other Officers Superannuation Act, 1922; in addition, motor car allowances in accordance with the Committee's scale and reasonable travelling expenses are paid.

The appointment is also subject to a satisfactory medical examination by one of the Committee's independent Medical Referees.

Forms of application and statement of the duties and terms of the appointment can be obtained from the undersigned. Applications, marked "Medical Superintendent," with copies of not more than three recent testimonials, must be received by me not later than Monday, *May 26th.*

Applicants must not be over 40 years of age. Canvassing, directly or indirectly, will be considered a disqualification.

L. EDGAR STEPHENS,
42, Warwick Street, Leamington. Clerk of the Joint Committee.
April 28th, 1930.

City of Birmingham.

SELLY OAK HOSPITAL.

APPOINTMENTS.—Contd.

Borough of Reigate.

APPOINTMENT OF MEDICAL OFFICER AT THE MATERNITY AND CHILD WELFARE CENTRE.

The Town Council invite applications from men and women Medical Practitioners for the above appointment for one year as from June 1st next. The salary will be after the rate of £150 per annum.

The duties, which must be strictly adhered to, comprise attendance at two sessions of two hours each on Tuesday and Thursday afternoons from 2.30 to 4.30 at the Health Centre in connection with Infant Welfare; and one session of two hours each month, on Wednesdays, for Ante-natal work, commencing at 2.30. The Medical Officer to arrange for a Locum Tenens in the event of his or her inability to attend.

The other duties and conditions attaching to the appointment can be obtained upon application to the undersigned.

The regulations of the Ministry of Health of February 6th, 1930, require that the Medical Officer of an Ante-Natal Clinic shall either have held such an appointment with the approval of the Ministry prior to April 1st, 1930, or who, subsequent to qualification, has had at least three years' experience in the practice of his profession and special experience of practical midwifery and ante-natal work.

Sealed applications, marked "Medical Officer—Infant Welfare Centre," should be sent to the undersigned at the Municipal Buildings, Reigate, not later than Monday, May 19th.

Dated this 30th day of April, 1930.

ALFRED SMITH, Town Clerk.

Royal Victoria Infirmary,
NEWCASTLE-UPON-TYNE.

The House Committee of the Royal Victoria Infirmary, Newcastle-upon-Tyne, invite applications for the post of HONORARY ASSISTANT GYNÆCOLOGIST.

According to statutory provision every candidate must be registered in Medicine and Surgery.

Applications, with copies of three recent testimonials, must be sent to the House Governor and Secretary, Royal Victoria Infirmary, Newcastle-upon-Tyne, not later than Monday, May 26th.

The appointment will be made on Thursday, June 5th.

Personal canvassing will be considered a disqualification for office.

S. DUNSTAN,
May 5th, 1930. House Governor & Sec.

Hospital of St. John and
ST. ELIZABETH,
60, Grove End Road, St. John's Wood, N.W.8.

There is a vacancy for the post of Temporary ANÆSTHETIST at the above Hospital during the illness of a member of the Anæsthetist staff. Honorarium at the rate of £50 per annum. Applications must reach the undersigned, from whom further particulars may be obtained, on or before May 12th.

F. DUDLEY HOBBS, B.A.,
Secretary.

Full Schedule of Terms and Conditions will be forwarded on application.

The Menace of the Overloaded Bowel

always present, easily becomes serious in women. It causes interference with the pelvic circulation and tends to produce congestion of the uterus, not infrequently followed by functional disorders, producing dysmenorrhœa, menorrhagia, and even inflammatory conditions.

AGAROL Brand Compound gives relief and frequently permanently restores the functional activity of the colon. One tablespoonful before retiring, gradually decreased as improvement takes place, is especially well adapted for the treatment of constipation in women, because of the gentle action of Agarol Brand Compound and absence of irritation from its use.

A liberal trial quantity at the disposal of physicians.

FRANCIS NEWBERY & SONS, LTD.

LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* Mineral Oil—Agar Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

THE CONSTIPATION SYNDROME

Whether the symptoms associated with constipation are partly toxaemic or entirely due to neuro-muscular disorder, there is no doubt about their reality or their gravely disturbing effect on bodily and mental efficiency.

The influence of emotion, acting through the mediation of the sympathetic nervous system, on bodily processes—markedly on those concerned with alimentation and elimination—is reversible; the psychic consequences of discordant activity of the involuntary muscles being no less striking.

Many vague discomforts and disturbances of health which are often brushed aside as neuroses, or as consequent on undefined focal infections, are, in fact, brought about by disharmonized or ineffective peristalsis.

Thus, we suggest, is explained the undoubted benefit which patients suffering from such disturbances often derive from a morning glass of Eno's "Fruit Salt," taken regularly over a period of a few weeks. In addition to—or by reason of—its purity and its complete freedom from such mineral salts as Epsom and Glauber, Eno is pleasant and refreshing to the palate, as well as effective in action. It has the further merit of being *non-habit-forming*.

"The Doctor's Emergency Reminder."

The Proprietors of ENO's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "The Doctor's Emergency Reminder" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

£980

End Results of Diabetic Foot by Conservative Treatment

"I highly recommend dressings with hot Antiphlogistine, which has a softening and resolvent action, hastening, in advanced cases, the sloughing of the necrotic tissue and core without pain and danger to the patient."

—From "Die Reizkoerperbehandlung des Diabetes," by Professor Dr. Gustav Singer, head physician at the Rudolfstiftung Hospital, Vienna.

Furuncular and Phlegmonous Complications of Diabetes

IN seemingly hopeless cases, if the general condition, metabolism and local processes do not endanger life, simple and conservative treatment should be patiently applied with the help of careful and persistent resort to minor surgery.

Surgeons, more and more, are inclined towards the Conservative Treatment of Furuncles and Carbuncles, especially those of Diabetics, and some of them even go so far, in many cases, as to refrain from incisions and to rely on outward applications.

Antiphlogistine

by hastening the disintegration of the exudates and toxins and by stimulating cellular activity, is an appropriate topical application, producing definite physiological reactions, which are the basis of all healing.

Depletant!

The Denver Chemical Mfg. Co.
London, E.3.

You may send me literature and sample of Antiphlogistine for clinical trial.

THE ENDOCRINES IN GENERAL MEDICINE

By

W. LANGDON BROWN, M.A., M.D., F.R.C.P.

"The combination of early physiological work, clinical experience, and wide reading has enabled Dr. W. Langdon Brown to write a clear and philosophical handbook full of suggestive ideas on the difficult subject of the Endocrines in General Medicine."—British Medical Journal.

"Written for the practitioner, who will find in it an account of the endocrine system and its diseases presented in a form which should certainly be of service to him."—The Lancet.

"The author gives a well-balanced review of present-day knowledge regarding the endocrine glands, summarizing the subject in such a way as will be of service to the general practitioner."
—The Prescriber.

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.),

Senior Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.
Demy 8vo. Pp. 534. With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

"The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

"We think that most of our readers engaged in general practice will find this work extremely useful."—THE JOURNAL OF CLINICAL RESEARCH.

"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW

"A book which we believe is destined to remain the standard work on Cardiology for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

OXFORD UNIVERSITY PRESS, Amen House, Warwick Square, London, E.C.4.

"Should be in the possession of every medical man."—*Glasgow Medical Journal.*

AN ACTUAL CONVERSATION:

MEMBER: "I have called to congratulate you on the manner in which you have brought the Browning case to a successful issue.

SECRETARY: "It certainly *was* a very difficult case, and we are naturally proud of our success.

MEMBER: "How did you succeed in tracing him, Mr. Watson?

SECRETARY: "We have a very unique source of enquiry, and although you could not supply us with the Debtor's initials, we were able to find those out, owing to the fact that you gave us the date when you attended his family last at Sutton. The Debtor's Christian names and our various enquiries enabled us to ultimately locate him. Five different addresses were obtained.

MEMBER: "Yes, I observed there were FIVE TRACINGS, Mr. Watson, but what pleased me most was the way you smashed all his arguments.

SECRETARY: "I have been dealing with disputations and argumentative debtors all my life."

A NEW CAR—FOR AS LONG AS YOU PLEASE

Because a car is so necessary to the practice, its cost should be calculated as a professional expense. Our guaranteed repurchase plan makes this calculation a comparatively simple one.

You let us know the make and type of car you prefer and we send you a list of suitable cars. Before you buy, we guarantee to repurchase the car at an agreed price at the end of an agreed period. The period, like every other condition of this plan, is arranged to suit your convenience. After purchase, the car is yours. There are no inspections, no irksome conditions, and no restrictions on mileage.

This plan fixes the cost of ownership because it avoids the risk of loss at resale. It is cheaper than hiring, you enjoy the benefit of the full ownership and you may change your car just when you please. Finally, because it is planned with a sure knowledge of what is helpful and necessary, you will find our Guaranteed Repurchase Plan infinitely convenient. May we send you full details of this service? They are awaiting your enquiry.

THE DERMASEPTIC QUALITIES OF PEAT

Only during the past 10 or 15 years have the therapeutic qualities contained in peat come to light.

The peat distillate principle—an acknowledged remedy for skin troubles—is embodied by the makers of Sphagnol in various media. In their ointment, soaps (medical, toilet, and shaving), lotion and suppositories, the strength in all cases being from 5 to 15 per cent., the medium is of the purest quality. The preparations can be purchased at all chemists. The prices are reasonable.

No absurdly extravagant claims are made. The makers simply wish to state that the peat distillate principle is embodied in SPHAGNOL.

Medical practitioners who desire to try this product are invited to send for a trial box of samples.

Local Anæsthesia in Surgical Practice

FRACTURE OF THE RIGHT FEMUR.

Typical Case.

Mrs. S. E. B., aged 71 years.

Diagnosis: Supra-condyloid T-fracture of the right femur.

Operation: Incision, reduction, and application of screws.

Anæsthesia: Transverse infiltration block.

Technique of Anæsthesia: Infiltration block. Novocain-Adrenaline 150 c.c. The patient was given no preliminary hypodermic medication. She was placed on the extension apparatus, great care being taken to make her as comfortable as possible. She was held in position by applying the extension screws, and the skin was prepared by painting with iodine. The line of incision—25 cm. in length—was infiltrated, each excursion of the needle bringing its point in contact with the femur. An especially large deposit of solution was made just posterior to the bone in the region of the fracture. The bone was exposed and the fragments gently separated by the use of a scalpel and chisel. In the meantime the traction screws were brought into play, and the lower fragments were gradually brought down to the proper level. One long screw and a stove bolt were introduced, after drilling the bones, in order to prevent a recurrence of the displacement after operation, the fractured surface being rather oblique. This patient left the table with a pulse of 70; there was no haemorrhage, no shock, no pain, and she presented no post-operative complications.

—EXTRACT from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

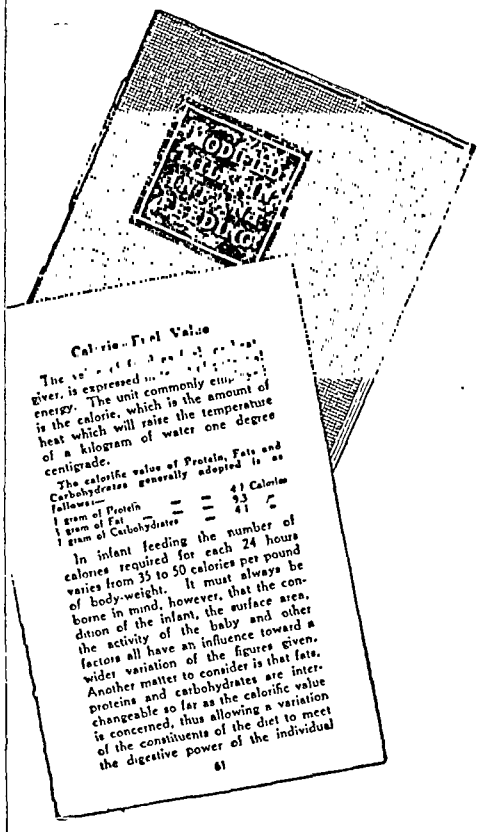
WILL YOU ACCEPT ¼lb. GRATIS?

In order that Doctors all over the country may test the tea their colleagues have so generously recommended, we will send ¼lb. free to any medical man who will write for it. This offer applies solely to members of the Medical Profession.



DOCTOR'S CHINA TEA

FOR many years Doctors have recommended our China Tea to Invalids and Dyspeptics when ordinary tea was out of the question. The Medical Press, too, has commented frequently upon the merits of this particular blend—and so we call it DOCTOR'S China Tea. It is a perfect blend of the finest China leaf with all excess tannin eliminated. Invalids and dyspeptics can drink it with no ill effects.

Priced at 3/- and 3/8 per lb. A super quality at 4/2 per lb.

CVS5

Mellin's Food

proves invaluable in the dietary of under-weight babies. Its beneficial effects are due to the high percentage of malto-dextrin which it contains and to its action upon the casein of the cow's milk with which it is prepared in the proportion directed by the doctor.

In cases of fermentative diarrhoea, Mellin's Food is advocated because the maltose and dextrose which it yields are entirely absorbed by the small intestine. Its use is accompanied by a steady and healthy increase of weight.

Members of the Medical Profession should send for a copy of the pamphlet "Modified Milk in Infant Feeding," which will be forwarded with sample, post free, on application to:

MELLIN'S FOOD Ltd., LONDON, S.E.15

Medisoap Therapy

A great advantage of the therapeutic use of Medisoaps is that the intensity of action of the medicaments may be increased or modified by varying the manner in which they are used.

Medisoap Midgley No 19

In this formula are combined the disinfectant and antiparasitic properties of Sulphur and Peruvian Balsam, with the direct cutaneous stimulation obtained by Camphor. It has been found to be very helpful in conditions such as chronic psoriasis, comedones, dermatitis, eczema, scabies and the various scaly conditions often so obstinate and unpleasant.

OVALTINE

WHEN SLEEP IS DIFFICULT

Judged by the numerous reports received from physicians and also from grateful patients, the use of "Ovaltine" for ensuring sound refreshing sleep deserves the widest recommendation.

It has been remarked that a more helpful prescription could not be wished for because:

1. Taken last thing at night before retiring it exercises a pronounced sedative effect and one that is natural in every sense.
2. It has a pleasantly soothing action on the stomach and nervous system, and does not cause the slightest digestive unrest, or occasion constipation.
3. It promotes a sufficiency of healthful sleep without recourse to hypnotic drugs.

"Ovaltine" is a delicious concentrated extraction of malt, milk, and eggs, in the form of golden granules, which dissolve instantly in milk.

A liberal supply for clinical trial sent free on request.

Calcium Deficiency in Expectant & Nursing Mothers

Pregnancy and lactation often produce manifestations of calcium deficiency because the calcium reserve cannot meet the demands made upon it. The systematic use of Kalzana in these cases stays the destructive processes in the teeth and bones of the mother, and ensures normal development of the skeletal structure of the infant. The special feature of Kalzana is that it combines calcium lactate and sodium lactate in the form of a double salt, with the result that the sodium element improves the blood alkalinity to the extent necessary to ensure adequate calcium retention.

"The Practitioner" says:

"Kalzana acts efficiently in promoting the growth of strong bones and healthy teeth, in protecting the expectant and nursing mother against a dangerous loss of calcium . . . . particularly because Kalzana promotes calcium retention."

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

calcium-sodium-lactate

Also supplied *direct* for Doctor's own dispensing at 15/- per 1000 plain tablets.

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

M-A-B

ACIDOPHILUS BACILLUS *IN A NEW FORM*

MULFORD ACIDOPHILUS BACILLUS BLOCKS are a concentrated, mass culture of the Lacto-bacillus Acidophilus, incorporated in agar jelly and protected with a chocolate coating.

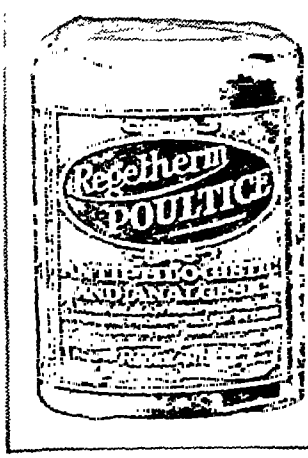
MULFORD ACIDOPHILUS BACILLUS BLOCKS, M-A-B, are used for the establishment of Acidophilus Bacillus in the intestines, supplanting the putrefactive bacteria, which flourishes under modern diet, and restoring a normal bacterial condition approximating that of early childhood.

ADVANTAGES:

Concentrated cultures of living Acidophilus Bacilli, each block containing 150 billion organisms at time of issue.

The required large dosage in small volume. An effective vehicle for carrying the bacilli to the lower bowel where they supplant the objectionable bacteria.

The most convenient, attractive, palatable, and economical way of taking the Acidophilus treatment.



Effective—yet entirely free from laxatives, cathartics, or drugs of any kind.

A full-sized trial package and literature sent free to any member of the Medical Profession.

REGETHERM POULTICE

(Cataplasma Kaolini. B.P.C.)

CLEAN & CONVENIENT IN USE

More certain in its action than the old-fashioned poultice.

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover, the ingredients are so balanced that this action does not set up any counter-irritation, but allays pain, ensures an even circulation through the congested areas, and thus induces natural and pain-free rest.

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices, and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial, or of deep-seated origin.

PRICE 2/- PER 1-lb. TIN

(NOTE THE WEIGHT).

Full size trial sample free to any medical practitioner, in British Isles on application by postcard to Boots the Chemists, Station St., Nottingham

NATURAL

CARLSBAD SPRUDEL-SALT

Prepared only by the Municipality of Carlsbad from the World-famous Sprudel "Spring" at Carlsbad
(IN CRYSTALS OR POWDER)

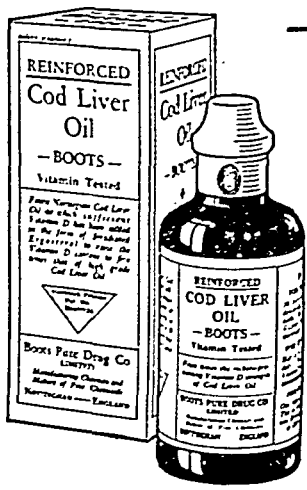
Is the Only Genuine CARLSBAD SALT.

Largely prescribed in cases of Chronic Gastric Catarrh, Hyperaemia of the Liver, Gall-stones, Chronic Constipation, Diabetes, Renal Calculi, Gout, and Diseases of the Spleen, arising from residence in the Tropics or Malarious Districts.

Medical Practitioners should kindly note, when prescribing, to specify "Carlsbad SPRUDEL-Salt" on account of the many artificial preparations upon the market.

The wrapper round each bottle of genuine Salt bears the Signature of the Sole Agents:

INGRAM & ROYLE, LTD.,



BANGOR WHARF, 45, BELVEDERE ROAD, LONDON, S.E.1.
And at LIVERPOOL and BRISTOL.

REINFORCED COD LIVER OIL —BOOTS

THE therapeutic value of Cod Liver Oil is fully appreciated by the Medical Profession. It is recognised for its specific action (due to its high content of Vitamins A and D) in rickets, affections of the chest, and diseases arising out of malnutrition. Boots Reinforced Cod Liver Oil is a biologically controlled preparation containing five times the amount of Vitamin D in addition to the normal amount of Vitamin A. The advantage of a concentrated oil needing only a fifth of the usual dose will be particularly valuable. Four fluid ounces of Reinforced Cod Liver Oil —Boots, contain the same amount of Vitamin D as one pint of the finest Norwegian oil.

In 4-oz. bottles, 2/6.

Independent Evidence by a Leading Professional Journal.

56 THE NURSING MIRROR AND MIDWIVES' JOURNAL. APRIL 19, 1930.

The Nurses' Materia Medica.
A GUARANTEED GUIDE.
By Our Analytical Experts.

No. 16.—ROBOLEINE.

HAVING heard a good deal of the virtues of Roboleine as a good "body-builder" in cases of malnutrition, we selected a sample of this food for analysis by our experts this week, as we desired to know whether it was really as good as it was reported to be. The result has proved that its makers, Oppenheimer, Son and Co, Ltd, are justified in claiming that it contains all the vitamins at present known to medical science, and that it is an excellent digestive food. The sample analysed was found to contain the following :—

	Per cent.
Moisture	23.23
Fatty matter	4.04
Mineral matter	1.72
Phosphate as P_2O_5	0.73
Nitrogen	0.06
Equal to protein (Factor 6.38) ...	0.38
Maltose	52.00

Lecithins and citralis were also present.

Roboleine is no new product. It has been in use for fully a generation, and proved itself valuable over and over again in cases of debility, loss of weight, malnutrition, sleeplessness, and especially so in tuberculous conditions. Nursing mothers have found both the quantity and quality of their milk improved by taking it, and for artificially fed babies it makes a useful adjunct in the diet. Full directions as to dosage are issued with each bottle, and nurses may feel quite safe in taking it themselves when feeling a little run-down, or in recommending a course of it to the convalescent patient just leaving their care. After influenza, typhoid fever, or any wasting condition, Roboleine should be taken regularly for three or four weeks while strength is returning.

The extract given shows the result of an independent analysis on a sample of ROBOLEINE purchased in the open market and made by the expert analysts advising a leading professional journal. The report shows that ROBOLEINE contains all the vitamins, and it confirms all the claims made for ROBOLEINE by the manufacturers, both as a body-builder and an anti-infective.

The Food that builds the Body.

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

TRADE **Endomin** MARK

Anaemia and its treatment. The use of liver has practically revolutionized the treatment of Anaemia, but it frequently gives rise to digestive disturbances. The metallic elements present in liver have a pronounced effect in increasing haemoglobin and red blood corpuscles.

Endomin—a hematopoietic based upon an entirely new principle—contains the essential metallic elements in a lipoid soluble readily assimilated tablet form. Packings of 100, 500 & 1,000 Tablets.

You are invited to send for a free stock size bottle to the Distributing Agents: Coates & Cooper, 41, Great Tower Street, London, E.C.3.

Manufactured by
REED AND CARNRICK
Pioneers in Endocrine Therapy
Jersey City, New Jersey.
South Africa: Lennon Ltd., Cape Town & Branches.

FORMULA

Each tablet contains in lipoid soluble form

Iron	8.0 mg.
Copper	0.6 mg.
Manganese	0.4 mg.
Zinc	0.3 mg.
Nickel	0.03 mg.
Cobalt	0.03 mg.

with the addition of

Sodium Germanate	0.05 mg.

'PANOPEPTON'

LEAN BEEF—the entire group of nitrogenous substances, those natively soluble and those rendered soluble by physiological hydrolysis, amino-acids, and polypeptids, with the natural savoury extractives and minerals.

ENTIRE WHEAT GRAIN—the peculiar complex of nitrogenous substances, those naturally soluble and those rendered soluble by physiological hydrolysis, amino-acids, and polypeptids, the farinaceous substance converted into dextrin and maltose, and with the associated savoury constituents and minerals.

Of the beef nothing is excluded but the indigestible connective tissue and lipoid. Of the wheat nothing is excluded but the insoluble inert cellulose and silica of the shell of the grain.

'Panopepton' is of a uniform standardized composition: it is highly agreeable: requires no preparation. It is a potent restorative and emergency food in serious straits; a fortunate recourse for the invalid.

Suppled in 12-oz. bottles.

AMYL NITRITE "STERULES"

(MARTINDALE—Regtd. T.M. & Design)

IN BOXES OF 12 "STERULES"

Containing 1, 2, 3, 4, 5, 6, or 10 minims (0.05, 0.1, 0.2, 0.25, 0.3, 0.35, or 0.6 c.c. approx.), the usual dose being 3 minims (0.2 c.c.).

For relieving ANGINA PECTORIS, SPASMODIC ASTHMA, MIGRAINE, POST-PARTUM HAEMORRHAGE, HAEMOPTYSIS, SEA-SICKNESS, to ward off EPILEPTIC ATTACKS, etc., and as an ANTIDOTE to CHLOROFORM; it is largely employed in threatened FAINTING and COLLAPSE, and as a RESTORATIVE after GAS in DENTAL OPERATIONS.

Abstracts from the medical literature:

ANGINA PECTORIS: "The best remedy. To lower blood pressure has a more rapid action than any other drug, and is useful in cutting short the paroxysms of pain." —L., ii/05, 325; ii/06, 1335.
"Gave prompt relief in the more pronounced attacks." —B.M.J., ii/06, 304.
"In all spasmodic affections, such as angina pectoris, one of the best remedies."—B.M.J., i/09, 994.
"The nitrites are indispensable."—B.M.J., ii/09, 1122.
"The quickest means of relieving the acute pains." —L., ii/08, 1132.
"Fear of death entirely disappeared."—L., ii/09, 572.
"No drug can compare with Amyl Nitrite."—L., i/09, 240; L., ii/05, 812.

INTRATHORACIC ANEURISM: "For the acute anginal attacks Amyl Nitrite inhalation, followed by internal use of Nitroglycerin or Erythrol Nitrate, is generally efficacious."—L., i/13, 948.

ASTHMA: "In most cases the reduction in blood pressure relieves."—B.M.J., ii/11, 1327.

POST-PARTUM HAEMORRHAGE: "Immediately stopped; no further trouble followed."—B.M.J., ii/06, 1125.

HAEMOPTYSIS: "With few exceptions, promptly effective. Secures peace of mind to sufferers." —L., i/08, 130.
"Some convincing cases in which it saved life." —L., i/07, 939.
"Amyl Nitrite the drug par excellence; acts better the quicker it is used."—Edin. Med. Jl., 1904; L., ii/04, 522, 942, 1446; B.M.J.E., i/06, 79.
"In severe haemoptysis—rupture of an atheromatous pulmonary vessel—free use satisfactory."—B.M.J., i/06, 917.

SEA-SICKNESS: Very useful; inhalation repeated every 2 or 3 hours if necessary.

CHLOROFORM SYNCOPE: The quickest means of restoring the heart's action.

INFANTILE CONVULSIONS: Well treated by 1 mm. "Sterule."

PLEASE SPECIFY MARTINDALE'S AMYL NITRITE "STERULES"

We also supply other vasodilators, e.g.:

MANNITOL NITRATE TABLETS: 1 gr.
ERYTHROL NITRATE TABLETS: ¼, ½, and 1 gr.

MONSOL
in
MIDWIFERY

The antiseptic employed in midwifery must be both germicidally powerful and at the same time safe and free from danger.

Monsol is the ideal preparation in such cases because:—

(1) *It is selective in its action on streptococcal bacteria, being 10 times as powerful as lysol in this respect.*

(2) *It has a perfectly non-irritant action on the tissues and mucous membranes at therapeutic concentrations.*

(3) *It keeps the hands and skin soft and does not roughen them.*

(4) *Is is a standard product and never varies in composition.*

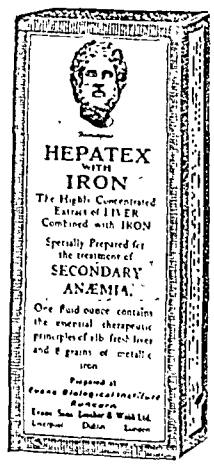
Authorities competent to judge have expressed the considered opinion that the use of Monsol in midwifery reduces the incidence of puerperal sepsis by fully 90%.

Other authorities have also stated that certain lysol and cresylic acid preparations are not efficient germicides against streptococci without being used at concentrations which involve grave risk of injuring the tissues.

Monsol is so bland in action that it can safely be used at strengths far greater than germicidally necessary without any risk of causing irritation.

MONSOL PREPARATIONS INCLUDE:
MONSOL LIQUID, OINTMENT, INTERNAL CAPSULES. PASTILLES, DENTAL CREAM, TOILET SOAP, ETC.

Manufacturers:
The Mond Staffordshire Refining Co., Ltd.
Abbey House, London, S.W.1.



Trade enquiries to:

THE SAFE GERMICIDE

(Aesculapius)

HEPATEX WITH IRON

For the Treatment of Severe Secondary ANAEMIAS

Issued in 2-oz. bottles 7/6 each. Brochure on application.

For the treatment of the severe secondary anæmias the use of liver in itself is of inconstant value. Likewise the administration of iron, while undoubtedly beneficial, does not always ensure that degree of improvement which is desirable. Liver and iron combined, however, have proved most effective.

HEPATEX WITH IRON provides a rational treatment for severe secondary anæmias. One drachm contains the essential therapeutic principles of 2 ozs. liver and 1 grain of iron. This iron, compared with ordinary iron preparations, is greatly superior as regards assimilation and absence of gastro-intestinal disturbances.

Intestinal Stasis and Vitamin Deficiency

By "Pathologist"

One of the commonest ailments with which the general practitioner has to deal is that known as "Intestinal Stasis."

The rhythmical Peristaltic Wave has been thought by some authorities to be due to the bulk of the food present in the bowel after digestion (roughage).

Serious doubts have been cast upon this view by a series of experiments upon rats conducted in the Bemax Laboratories during investigations into vitamin activity, as animals fed on large quantities of food with much roughage became constipated, but when the roughage containing vitamin B was added there was no constipation.

During post-mortem examinations on a number of animals it was repeatedly observed that in animals fed on a Bemax diet—rich in vitamin B—peristalsis persisted for fifteen or twenty minutes after death, whereas in animals on a vitamin deficient diet peristalsis was absent or ceased a few moments after death, and could only be stimulated for one or two contractions by a physical stimulus.

Animals fed on a diet deficient in B vitamin show marked symptoms, significantly akin to those exhibited by men and women who seek treatment for intestinal stasis. Subnormal temperature is common; loss of appetite is a marked symptom, followed by lack of growth, malnutrition and constipation. Paralysis and convulsions ensue if a completely deficient diet is persisted in. This is completely cured by the administration of Bemax.

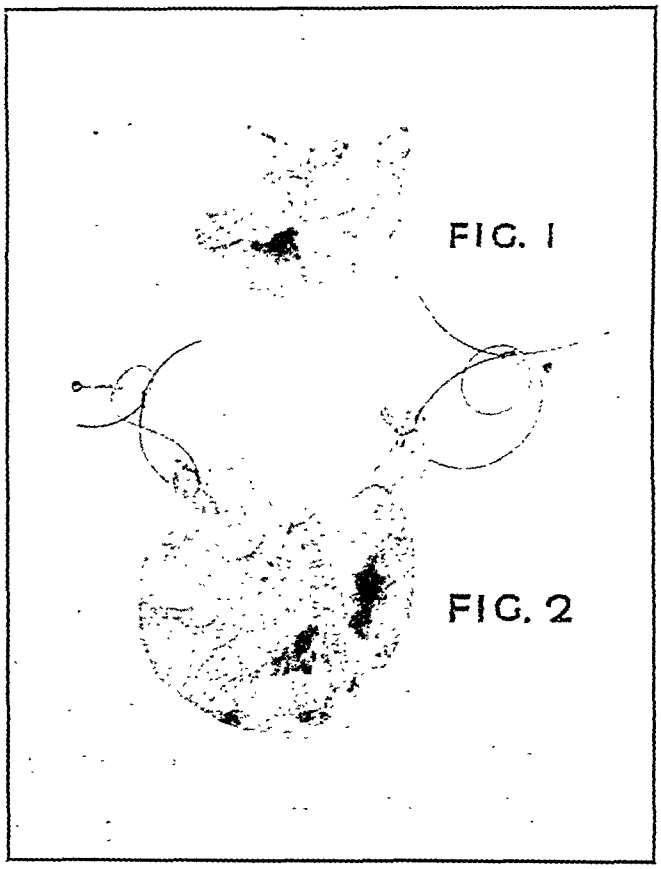

Fig. 2 shows the caecum of a rat fed on a partially deficient B vitamin diet, and Fig. 1 of a rat on the same diet but to which 10% of Bemax was added.

Detailed reports of further research work will be sent on request to any medical man interested.

INTERIOR OF THE BASILICA OF SANTA SOPHIA, "ONE OF THE FOUR GREAT PINNACLES OF ARCHITECTURE."—This miracle of building has been placed by experts as third of the four outstanding masterpieces of architecture. It is of all monuments the one pre-eminently entitled to the designation "Byzantine." Its principles of construction, taken as a whole, were new to the world, and the pioneers who planned it were the architects, Anthemius of Tralles and Isidore of Miletus, both in Asia Minor. These carried out the dream of the Emperor Justinian. The illustration shows the central area of the immense cathedral. The interior is sheeted with the rarest marble, from the ground up to the lower range of capitals. The space above, including the dome, is overlaid with mosaics. The pillars of the central nave are of verde antique; others are of porphyry, certain temples of Ephesus, Palmyra and elsewhere having been despoiled to supply the marble. Silver was used for lining the upper walls of the sanctuary. Vast though the undertaking was, the building was completed in the almost incredibly short space of five years. Ten thousand workmen were employed upon the task and were roused to great enthusiasm by the emperor, who visited them in their yards.

An Oration
ON
THE INEXORABILITY OF THE LAW OF EVOLUTION AS MANIFESTED IN MODERN MEDICINE.

DELIVERED TO THE MEDICAL SOCIETY OF LONDON ON MAY 12TH, 1930,
BY
SIR ARTHUR KEITH, M.D., F.R.S.

Medical London Fifty Years Ago.

FIFTY years ago a walk round Harley Street, Queen Anne Street, and Wimpole Street provided a medical visitor from the country with quite an interesting morning. The names on the door-plates were already familiar to him; for the greater part they were those of physicians and surgeons on the staffs of our leading hospitals. The physicians were mostly general consultants, but fame, he knew, had given some of them a reputation for being particularly skilled in certain diseases. The surgeons, too, exercised their art on all parts of the body, but already specialization had taken hold and some were devoting themselves to particular disorders, such as those of the urino-genital system, or even confining themselves to definite organs or systems of the body, such as eye, ear, nose and throat, teeth, skin, and such as required orthopaedic treatment. Our visitor would also have come across the names of men who had made their reputation in the practice of midwifery and diseases of women—a specialty which in 1880 was at least a century old.

Spencer's Law of Progress.

Our country friend, if he were familiar with Herbert Spencer's law of progress*—namely, that it was merely another name for increased specialization—would have found an opportunity, in the three streets just named, of studying the application of Spencer's law to medicine. Of the 120 men who at that time had segregated themselves from the army of practitioners and taken up an abode in the three streets, some, although on the staffs of hospitals, did engage in family practice; others were not on any hospital staff, but sought prestige in practice from their place of residence; the vast majority, however, were consulting physicians, surgeons, or obstetricians, or were specialists in one branch of these three main divisions. Their numbers represent the extent to which medical specialization had spread in the year 1880.

The Rate at which Specialization is Growing.

Were our visitor to return now, after an absence of fifty years, he would be astounded at the rate at which the wheel of evolution has moved in our medical world. Familiar names have disappeared from the doors of our three streets and been replaced by others—quite as noteworthy. The brass plates have decreased in size, but greatly increased in number; a census shows that the 120 of 1880 have been replaced by 954 in 1930. While the medical population of London (and the same is true of the provinces) has only a little more than doubled its numbers in the last fifty years, the army of specialists, in the three streets already specified, has undergone an almost eightfold increase. Progress signifies that the number of young medical men who turn aside from general practice for a specialty becomes ever greater. Everyone whose name is affixed to a Harley Street door is not necessarily a specialist, but after making all allowance on this score, there are certainly seven specialists now where there was only one fifty years ago.

How specialization has sped may also be seen from the fact that the Royal Society of Medicine finds it necessary to divide its proceedings into twenty-four sections. In our three streets we should certainly have to carry the subdivision farther and recognize about thirty-five branches of special practice in place of a bare ten of fifty years ago.

Ancillary Sciences determine the Rate and Mode of Medical Progress.

When we look beneath the surface of things and try to ascertain why the face of medicine has become so changed (and we may be certain it will continue to change) we see that the cause lies not so much in what medical men themselves are doing as in what is being accomplished in certain branches of science—particularly in chemistry, physics, physiology, pathology, and biology. The application of modern chemistry to medicine has called into being at least two groups of specialists, perhaps three. Advances in physics have opened three or four new fields of medical practice—for the application of x rays, radium, light, and electricity. Biology—in which we may reckon bacteriology, immunology, and vaccine therapy—has made and is making such progress that a greater number of specially trained men become necessary as medical advisers. The technical methods of the physiologist, pharmacologist, and pathologist are being brought more and more into clinical practice, giving those skilled in their use opportunities for fresh departures in special practice.

While the impetus to specialization comes from advances made in the ancillary sciences, our progress is also determined by the trend which events are taking in general medicine and surgery. As region after region of the body has become "safe for surgery," specialization has been found to be necessary for the patient's sake as well as for the further increase of knowledge. The same is true of medicine: knowledge regarding the ailments of each system of the body becomes so extensive and the technique needed for their full elucidation has grown so elaborate that it is no longer possible for one man to be master of all. As long as knowledge continues to increase and the methods employed to become more elaborate, division of labour—specialization—must also increase.

The Direction of Progress.

Thus we see that "progress," which is another name for "evolution," has transformed the face of medicine as practised in the West End of London in the space of time easily covered by living memory. What will be its state in another fifty years? Let us see how far Herbert Spencer in 1880 could have foretold the state which medicine has actually reached in the three streets at the present time. He would have premised that the same spirit—a spirit of humanitarianism—would continue to urge medical men onwards in their attempt to relieve mankind of its load of suffering. He would have been certain, if this were so, that knowledge must increase, and with each increase must come an augmentation of specialism. But he could not have foretold the direction in which specialism would spread. Our progress has been determined not by deliberate choice but by the force of circumstances, over which, for the greater part, medical men have had no control. That is what I mean by the "inexorability of the law of evolution as manifested in modern medicine." There is behind the medical army an irresistible pressure which thrusts it forward into the future, and it must march, not as it would, but as it needs must.

Evolution as seen in Medical Schools.

I have carried you to Harley Street to give me an opening for my thesis, but now, for the better understanding of the forces involved in medical progress, let us pay a visit to one of our larger teaching hospitals. Let us suppose that after having been in practice abroad for fifty years we are paying a first visit to our old hospital. What do we find? When we left the medical school of the hospital it was manned entirely, or almost entirely, by members of the hospital staff—surgeons and physicians. There were only two exceptions—a chemist and a biologist. Now we find the departments of the school greatly increased in number, and every one of them presided over by a man who, although trained for the practice of medicine, has elected to devote himself to teaching and research in one of its basal subjects. Physiology, taught by a surgeon when we left, has now widened its scope to such an extent that it has been found necessary to have it subdivided into three branches, each in charge of an expert. What strikes us most in our modern school is the birth of laboratories; medicine has passed into a new period—the laboratory period. When we left there was only one—the dissecting room—but now we find the old school trebled in size to accommodate great rooms for the practical study of pathology, bacteriology, pharmacology, physiology, and chemistry. In place of a plain post-mortem room, in which physicians on the staff taught us how examinations on cadavers should

* Progress, its Law and Cause, *Westminster Review*, 1857. Reprinted in *Essays, Scientific, Political, and Speculative*, 1858, vol. i, p. 1.

be made, there is now a great institute of morbid anatomy over which a director presides, and has at his command a highly trained staff—all duly qualified medical men.

Evolution is at work in our Hospitals.

In the hospital itself we find ample evidence of how potent a factor the laboratory has become in our modern advance. In place of little closets annexed to certain wards, each provided with a spirit lamp, a few test tubes, and bottles of reagents, we now find suites of laboratories—bacteriological, chemical, pathological, cardiological—each requiring a highly skilled medical staff. We find the Unit System and the Team System at work—physicians, surgeons, and obstetricians, devoting their whole time to the treatment of hospital patients, to teaching and to research. Amongst the members of the hospital staff, who have still to earn an income from consulting practice, the tendency to specialize has become more marked. The special departments of the hospital have grown in number, and everywhere we see evidence of increased technical outfit—demanding increased knowledge and skill. Under the working of Spencer's law of progress our medical schools and hospitals have undergone in these last fifty years a transformation which amounts to a revolution. The main agent in bringing about the evolutionary changes has been the introduction and spread of the "laboratory idea."

Humanitarianism as an Evolutionary Force.

Let us look for a moment at the underground forces which have speeded our hospitals and schools so quickly in the direction of division of labour and of specialization. Harley Street in the olden days had to carry a heavy burden; it had to gather enough from the rich to provide itself with the means of treating the poor in hospitals and in teaching the art of medicine. The rapid increase of knowledge, particularly in the basal subjects of medicine, and more especially the introduction of technical methods of research, made it necessary to man medical schools with specialists—all of them more or less imbued with that kind of spirit which places opportunities for scientific inquiry above those which lead to augmentation of income.

The period of the missionary professor in our medical schools was a brief one. The war brought about a financial crisis in the schools, and the State began to take a hand in their affairs. This intervention was impelled by two motives. There was, in the first place, a "heart" motive—the humanitarian principle that the poor should have, of its own right, as free an access to the best available means of treatment as the rich. The second was a "head" motive—namely, that every advance in medicine brought a clear gain to the public at large—which is the State. Through State subsidies, dispensed by various Government departments, but particularly by the University Grants Committee, it became possible to staff hospital schools and certain hospital services with medical men who could devote their lives to special branches of medical knowledge. Government has provided the sinews of war, and the vanguard of the medical army presses forwards at an unprecedented pace, but neither Government nor any power can determine or regulate the direction of the advance; that depends on what happens at a thousand points along the fighting front. Of one thing, however, we can be certain: every advance made in our medical schools will have its repercussion in the Harley Street quarter of our larger cities. The initiative has passed, or is passing, from the clinician to the laboratory worker; the laboratory has become the "pace-maker" of medical progress.

The Divorce of Research from Teaching

My aim is to ascertain how far Spencer's law of progress helps us to understand developments which are happening under our eyes in our medical world. There has been an unparalleled increase in our knowledge; that has been accompanied, as Spencer postulated would be the case, by a necessary increase in specialization. In our present ranks I see a separation of duties, a division of labour, which, although I know it to be inevitable, yet fills me nevertheless with some pangs of regret. It is the separation of teaching from research. Time was when games were the pastimes of amateurs; to develop games to their highest pitch the professional became necessary. It was also so with research; it was the pastime of amateurs. Fifty years ago if a medical man had a bent for investigation he sought for a teaching post which would permit him to earn his bread-and-butter and at the same time offer him the opportunities he desired. Such a man became a source of inspiration to his students—particularly to his best students. To gain his end, and for the advantage of his subject, he was willing to offer up his wife and family as an economic sacrifice. There was in these sturdy pioneers a quality which commands our highest respect, and we shall say good-bye to the type with the utmost regret. Go it must, I fear; the imperious law of progress, which dominates science as well as sport, demands the replacement of the amateur by the professional.

Professional Research.

The introduction of professionalism into medical research has been made possible by subsidies from State as well as from private sources. That such endowments are speeding up the rate of medical progress there is no doubt; we have only to consult the pages of the annual reports issued by the Medical Research Council, or to read the address which Sir Walter Fletcher recently delivered before the British Science Guild,* to have ample confirmation of my contention. The Medical Research Council, and the Royal Society to a lesser degree, are, to borrow Sir Walter's simile, watering the tree on which the fruits of science grow. They have planted in their research orchards only such trees as have proved their bearing capacity, and the results are promising. Nevertheless, the gardeners can but tend the trees; they cannot change their nature nor alter by regulation the kind of fruit they will produce. They can but water the ground and hope in the autumn to gather a profitable crop.

The introduction of professionalism into research illustrates very well a corollary of Spencer's law of progress. This far-seeing Victorian realized that every new departure, every discovery or advance, was attended by a multitude of secondary effects. The segregation of our most gifted investigators is impoverishing the medical staffs of our universities and schools. Our best teachers desire to be relieved of the duties of their office in order that they may devote their whole time to experiment or other forms of inquiry. The gift of teaching, of inspiring young men, of collating and disseminating knowledge, is being ranked below that of the ability to research. The ultimate result of assigning an inferior position to the teacher and to the book-maker is as likely, in the long run, to impede the progress of medicine as to accelerate it.

Results of Progress on the Output of Medical Literature.

Another result is a curious one. So prolific is the output of published researches from our laboratories that a regiment of specially trained men has become necessary to deal with it and make its assimilation by the medical profession possible. How great that output has become may be seen from recent numbers of the *Quarterly Cumulative Index Medicus*—for which we are beholden to our brethren in America. There are now over 2,000 medical journals and periodicals; to index the articles appearing in these journals in the first six months of 1929, and the titles of medical books published in the same period, required 100,000 separate entries—these entries filling a volume of 1,311 pages. A friend, who has confined his researches to a small but important gland of the body, told me that the literature relating to it had become so vast that he could read only part of it. And yet the progress of medicine demands that the output will keep expanding at an ever-increasing rate, and specialization in research becomes more and more necessary.

There is no Alternative.

What, you may ask, is to be the end of it all? There is no turning back; we must press forwards. Will then our specialization reach such a growth that, like the monstrous antlers of the Irish deer, it will sap and endanger the life of the whole body of Medicine? There is a safeguard. When our specialization reaches a stage at which its upkeep passes beyond the powers of the public and private purse,

* See *Nature*, 1929, vol. cxxiv, p. 795; also *British Medical Journal*, 1929, vol. ii, p. 993.

then perforce we shall have to limit our ambitions and discover more economical methods of attaining our ends. As yet we are not within sight of such a crisis.

Co-ordination is a Necessary Constituent of Progress.

Up to this point I have been discussing the manifestations of progress as seen in the Harley Street quarters of our greater cities, in our medical schools and hospitals, and in our subsidized laboratories. In all three quarters we find medical men pressing forwards in search of new sources of knowledge, and as they press becoming subdivided more and more into separate groups. We have, in these instances, been studying only one of the factors of medical progress; there is another which Spencer perceived was equally inevitable. Specialization, if it worked unchecked, would tend to break up our medical forces and dissipate their strength in confusion. Hence we find, in the progress of our profession, just as in the evolution of the earlier animal organizations, there come into play certain unifying influences, exerted by a crude form of nervous system. An astute student of the evolution of medicine, if he had visited London in 1880, would have perceived that this nerve centre had already come into being in the form of a Department of State, situated in Whitehall—the Local Government Board. He would have found London already divided into fifty-two districts—each with a medical officer of health—controlled more or less indirectly by the nervous centre in Whitehall. All England, Wales, and Scotland had then become so divided, and a multitude of medical men, most of whom, while still continuing to attend to their patients, served also as members of a health army, and carried out a policy formulated or suggested in Whitehall.

The Process of Integration.

Unification or integration is just as necessary an ingredient of "progress" as specialization or separation. The influences which tend to bring about the unification of our medical army, like most of the inventions which alter medical practice, arise not inside our medical ranks but outside them. Before the middle of the nineteenth century it became evident to British statesmen that the country could not drift along exposing itself to plagues and pests, to contaminated water and adulterated foods, to overflowing cesspools and to drains which led nowhere. Government began tentatively by calling into being a new kind of medical specialist—the health officer. Presently it was found to be necessary to co-ordinate the activities of the men so enrolled. Even in 1880 this brain, then represented by the Local Government Board in Whitehall, was a small and simply fashioned organ. The deliberative and executive areas of its cortex were composed of laymen; eleven medical officers entered into its texture and were relegated entirely to the sensory or recipient areas. They were advisory in function at the most. No doubt the reformers who placed all our public health Acts on the Statute Book had to fight hard and long: they fought with head and heart, and deserved their victory; but, as they gained it, it never occurred to them that they were being impelled by force of circumstances, and were unconscious exponents of a scheme of evolution. Health reformation was initiated outside the ranks of our profession, but it introduced into our ranks the first step towards their unification.

We are the Slaves of Circumstance.

What I am seeking to make clear is that in all our advances we are the slaves of circumstance rather than masters of our fate. You may ask: Does not the Ministry of Health, which succeeded the Local Government Board in 1919, determine the direction in which we shall advance? Lately I listened to a speech which was broadcast by an able member of Sir George Newman's staff—Dr. T. Carnwath. In this speech the policy of the Ministry of Health was outlined. The Ministry watches how health measures, recently sanctioned by Parliament, work out in practice. Defects become apparent, the Ministry studies how they can be mended. Local authorities may apply for a special bill to meet some local need; if leave is granted, the Ministry notes the effects. If benefits accrue, then steps are taken to extend them to the whole country. The Ministry does not create its opportunities; it waits until they come, and then utilizes them for an "advance." Sir George Newman and Sir Walter Fletcher have both to wait for their opportunities. They wait patiently for them, and then when they occur apply their genius in utilizing them for the improvement of national health.

Progress implies an increasing Integration.

Every step taken by Parliament leads towards a more perfect unification of our British medical army—in which 34,000 recruits are now enrolled. We are far enough away from the angry discussions which arose in our ranks when Mr. Lloyd George successfully carried the National Insurance Act of 1911 to take a philosophical view of what then happened. We see now that it was the inevitable that happened: it was but another turn in the screw of that evolutionary movement which tends towards the unification—the integration—of Medicine. It was a continuation of that "policy" of the nineteenth century which broadened the franchise to its present limits, gave us compulsory education, established the medical inspection of schools, and more recently gave services for the welfare of mothers and babies. The Local Government Act, which brings the staffs of our hospitals more directly under a central authority, is but another turn of the same evolutionary wheel. The art of healing in its modern development is going steadily through the stages which transformed a brood of discrete independent protozoa into the co-ordinated complexity of cells which form the body of a living animal.

The Law of Evolution.

In this lecture I have been applying a law—the law of animal evolution—to the complex affairs of modern medicine. Given human nature as it is—a nature which demands, and ever will demand, that the poor must and shall have access, so far as health is concerned, to all the privileges the rich can buy, that at all costs suffering must be relieved—then medical progress must go on and follow the path already chosen. Further progress consists, in our modern interpretation, of an ever-increasing degree of specialization, and in an ever-increasing degree of co-ordination or unification. We cannot escape State control in the long run, however much we may regret the loss of personal liberty which is thereby entailed. What I would especially lay stress on is that medicine is not so free to choose its path into the future as most of us think it is. We may mould circumstances to our wills on some occasions, but in most we are carried along in the irresistible current of events. I do not mean we should, like fatalists, cease to strive to steer a course. Nevertheless in things medical, as in all mundane affairs, the main feature of the law of evolution is its inexorability.

A British Medical Association Lecture

ON

THE LOCALIZATION OF ABDOMINAL PAIN.*

BY

V. ZACHARY COPE, M.D., M.S., F.R.C.S.,

SURGEON TO ST. MARY'S HOSPITAL, PADDINGTON.

PAIN felt in the abdominal area may for practical purposes be divided into (*a*) pain arising from a pathological stimulus applied in some other part than the abdomen, and (*b*) pain in which the causative stimulus arises within the abdominal cavity itself. The localization of the pain in the first class of case is not very difficult so long as one realizes the possibility of the source being in some more remote part. A thorough physical examination of the patient will usually detect disease of the spine or spinal cord, or throw suspicion on to the chest, in cases where that region is to blame.

A very real difficulty may arise in those cases in which physical examination (including radiography) reveals nothing abnormal, and yet the patient avers that he has very severe pain in the abdomen. Speaking generally, such patients must be regarded as suffering from some real abdominal disorder until every means of diagnosis has been tried. Only after a failure of these and the inability to fit in the symptoms with any known clinical

* Given before the Leeds Division on March 6th, 1930.

condition must one allow the term "psychogenic" to be applied. It is very easy to shirk a full examination by saying the patient is neurasthenic. Neurasthenia covers a multitude of errors of diagnosis; nevertheless no one doubts that some abdominal pains may have their origin in mental disease. In such cases the patient often makes much more of his pain than is warranted by his fairly good general condition, while the term "agonizing" is more frequently used to describe the pain than in the case of those patients who have serious organic disease.

The localization of true abdominal pain is one of the most difficult problems with which the physician and the surgeon have to deal. The difficulties are inseparable from the anatomical configuration and the physiological interrelation of the various viscera. Anatomically the various viscera are so close one to another that the symptoms caused by disease of the one may easily be thought to emanate from another. Moreover, the mobility of certain parts of the intestine, and the way in which inflammatory or other fluid may travel quickly from one end to the other of the peritoneal space make error more easy.

Physiologically we are hindered in our quest by the vague diffuseness of the pain which is caused by acute visceral disease, and by the puzzling way in which a very great stimulus may cause a widespread extension or overflowing of the pain from the usual area associated with a certain visceral lesion. There is in addition a frequent confusion of reflexes—for example, pyloric spasm, which gives rise to pain of the gastric type, may be a reflex effect not only of duodenal ulcer but also of appendicitis or cholecystitis; while a painful distended colon may follow not only from colitis but from acute cholecystitis. Pathological difficulties in locating pain result from the occasional occurrence of multiple lesions, either independent or interdependent. To point this moral I am accustomed to quote a case which I saw eight years ago.

A man, aged 55, had acute abdominal pain especially in the right lumbar region. He was distended and had a great amount of free fluid in the peritoneal cavity. The liver was large and there were cardiac murmurs. He died without any operation being performed. At the necropsy the peritoneal cavity was full of pus and bile; the common bile duct was filled by large stones; there was a large hydatid cyst of the right kidney; there was aortitis with a small saccular aneurysm, and the foramen ovale was patent; there was healed tubercle at both the lung apices, and the pericardium was adherent. As if this was not enough, when the intestines were opened they were found to contain a large tapeworm.

located. In the case of acute abdominal pain, however, the clinical examination is perforce the most important, for momentous decisions have to be taken by the practitioner on the spot, and I desire particularly to be of assistance in cases of this nature.

Most cases of acute abdominal pain may be put into one of two categories: those due to obstruction of some tube or outlet of a hollow viscus, and those due to inflammation of a viscus with or without involvement of the peritoneum. These two classes of pain I shall consider separately. Both varieties are localized by the same aids, but the importance of the various aids varies greatly in the two cases. These aids are:

Spontaneous local pain,
Tenderness (evoked local pain),
Superficial hypersensitive ess,
Pain felt at a distance (referred pain),
Pain in contiguous viscera,
The shifting of pain, and the
Clinical history.

Pain caused by obstruction of a hollow tube, preventing the outflow from a hollow viscus, may be divided into two clearly defined groups. The first is the pain due to the stoppage of a canal without any accompanying occlusion of the blood vessels. Biliary colic due to a stone stopping up the cystic or common bile duct, renal colic consequent on a small calculus becoming impacted or passing down the ureter, uterine colic due to a small polyp or blood clot in the cavity of the uterus, intestinal colic due to anything kinking or obstructing merely the lumen of the gut, and a tubal abortion, serve as examples. In all of these the blood vessels supplying the affected part are intact. Now at the onset of any of these colics one is largely dependent for localization upon the clinical history and the position of the referred segmental pain; in such cases as intussusception and tubal abortion the clinical history may suffice to point accurately to the location of the pain, while in many other cases it is a most valuable help, and it is here that clinical experience may and does prove its great worth.

The position of the pain felt at a distance—referred pain—varies according to the case. In biliary colic it is commonly epigastric and right hypochondriac, and usually it is also felt in the right subscapular region. But the pain may be referred to the left hypochondrium, and I lately had a patient whose biliary pain was only felt in that position. The pain of renal colic, apart from perinephric irritation, is felt in the iliac regions, and radiates to the groin or testicle. When the renal pelvis becomes distended loin pain is felt and parietal irritation plays a greater part. Uterine colic causes pain in the lumbar and sacral region of the spine. Small-intestine colic is referred to the epigastric and umbilical regions, while that caused by the large bowel is felt chiefly in the hypogastrium. An acutely distended bladder will irritate the parietes so that its pain is located in front; but if the distension is gradual no pain is felt anteriorly, and the patient will only complain of pain in the lumbar region.

At the onset of these colics there is usually no tenderness on deep pressure, no muscular rigidity, and only occasionally hypersensitiveness of the skin. Far from intensifying the pain, pressure will actually relieve it, and in contrast with the immobility consequent on most inflammations the patient will often turn and twist about to find relief.

An interesting referred pain is that felt in the testicle in some cases of appendicitis. It is more common with a perforated appendix, but can occur either in right or left testicle with an unperforated appendix. In some cases it may be due to a direct irritation of the nerves in the spermatic cord, but in other cases there can be little doubt that it is a referred pain, and this has made me conclude that the appendix is at least in part supplied by the tenth segment of the cord which also supplies the testicle. Whether this is so or not the importance of the fact is clear, for the confusion of renal lesions with appendicitis is thereby made more easy.

When obstructive colicky pain has continued for some hours one or both of two consequences follow: either the viscus communicating with the obstructed tube becomes distended, or inflammation extending to the peritoneum or parietes may result. In both cases local tenderness supervenes this makes localization fairly easy. An acutely ll-bladder, an acutely inflated coil of

small intestine, and a tense pelvis of the kidney are all tender on pressure, and pain in them can be accurately located. The late Sir James Mackenzie used to teach that pain in the viscera was not actually felt in them, but was actually felt in the parietes as a referred pain; this view cannot now be maintained. Pain is certainly felt in the viscera, but it is not accurately located in them without the aid of the parietes. A tense or distended viscus cries out in an unknown language, which is interpreted by the parietes when palpated, the parietes indicating the site of the pain. This point can be made clearer by considering the manipulation of a distended coil when the abdomen has been opened under local anaesthesia. If the coil is outside the body the patient experiences diffuse central pain, but can give no idea of the exact position of the coil; when the coil is pressed upon through the abdominal wall he can tell the exact site of the pain. I always compare the function of the parietes to that of a piano keyboard in relation to a tone-deaf person. Anyone who cannot tell the difference between one note and another can still tell what note is being played if he looks at the note which has been struck on the keyboard. The parietes is a keyboard which indicates the site of pain felt in the intestines and other viscera.

In those parts of the intestine which have so short a mesentery that distension of the gut drags upon the parietes pain may be more or less accurately located. Most persons have at some time or other accurately located borborygmi in the ileo-caecal region and the iliac colon. The same spontaneous location of intestinal pain is possible when gut is adherent in the sac of an umbilical hernia: when gut is merely incarcerated it may not cause spontaneous local pain, but may be tender on pressure. How often superficial hyperaesthesia occurs from visceral irritation alone I am not prepared to state, but that such hypersensitiveness does occur without parietal irritation I am quite convinced. Its frequency is, however, so inconstant that it has very little practical value. I would emphasize again the point that colic in an uninflamed undistended viscus is not usually accompanied by local tenderness on pressure.

The second obstructive group comprises cases of occlusion or torsion of hollow tubes together with obstruction of the blood vessels going to the part; volvulus and obstruction by a band serve as examples. With this group should be classed the cases of strangulation of an ovarian cyst, or of a solid viscus, since the symptoms are somewhat similar. In all these cases the blood vessels are suddenly occluded and there is a sudden onset of pain and tenderness. The pain due to irritation of nerves in the pedicle or mesentery is diffuse and does not help in localization except as between the small and large gut, but local pressure will elicit the pain, and if the viscus is near the anterior or lateral abdominal parietes spontaneous local pain will be felt.

A special case is that in which only part of the circumference of a piece of gut is strangled; here very little distension may result, and since the nerves in the mesentery are not affected the adequate stimulus for even the visceral referred pain is absent. In these cases localization depends upon the spread of inflammation to the parietes, and if, as in some cases of femoral hernia, the related part of the parietal peritoneum is almost insensitive, localization may be very difficult. Hence the common overlooking of a Richter's hernia even when gangrenous. The stoppage of blood supply to a large portion of the bowel by a mesenteric thrombosis or embolism leads to generalized abdominal pain and tenderness from the first. At the onset the pain may result from irregular peristalsis, but later it is accounted for by distension and peritonitis. Diagnosis may be possible, but accurate localization of the part involved may be, and generally is, out of the question.

To sum up: In the early obstructive lesions without vascular occlusion localization is effected by the clinical history, and the distribution of the rather vague visceral referred pain; later there supervenes local tenderness depending on distension or inflammation spreading to the peritoneum. With obstructive vascular lesions local tenderness is present from the first.

Passing to the second large group of cases causing acute abdominal pain, the inflammations, it is noteworthy that bacterial infection of the interior of a viscus may, and often does, cause no pain at all. There may be little or no pain with an infection of the ducts in the liver, and sometimes even with suppuration in the branches of the portal vein. The entire absence of pain in some cases of liver abscess is well known. Infection of the renal pelvis, and of the interior of the uterus, may be practically painless. If pain is to be caused by infection of a viscus one of three things must happen: the duct (if there be one) must become obstructed so as to bring about distension; or the inflammation must spread to the parenchyma to cause oedema and tension; or the irritation must spread to the peritoneal coat and abdominal parietes. The first two possibilities have already been considered, leaving for discussion now the localization of visceral lesions by contiguous inflammation of the abdominal parietes.

The effect of irritation of the parietal peritoneum varies greatly according to whether there is a free or scanty somatic nerve supply. Irritation of those parts of the parietes which are supplied by the lower dorsal and upper lumbar spinal nerves causes local pain, tenderness on pressure, often a considerable reflex rigidity of muscles, and sometimes a certain amount of superficial hyperaesthesia. Inflammation of those parts which have a scanty nerve supply, or a supply derived from the sympathetic system, gives few if any of these indications for localization. Intermediate in its demonstrativeness between these two areas comes the diaphragmatic area, which causes local pain when its periphery is inflamed, but when the main part is irritated merely demonstrates that irritation by distant pain felt in the acromio-clavicular region.

In discussing this question I am accustomed to emphasize these points by dividing the abdominal lining into *demonstrative* and *silent* areas. By a demonstrative area I mean one which on irritation gives rise to pain, hyperaesthesia, and muscular rigidity, which demonstrate the site of the pain. By a silent area I indicate a part in which inflammation does not provoke spontaneous pain, does not give rise to cutaneous hyperaesthesia, and never causes rigidity of the parietal muscles. Pressure on an inflamed silent area may, however, cause a certain amount of pain. This broad distinction, which I propounded eight years ago, has not yet been generally adopted, but I consider it of the first importance. In the silent area inflammation may proceed with little pain and give no indication of its presence apart from the general symptoms, unless the irritation happens to spread either to a neighbouring viscus which may betray it, or to the demonstrative area of the parietes.

From a failure to recognize this distinction many grave mistakes in the localization of abdominal pain must result; cases of deep abdominal abscess have at some time or other proved puzzling, and escaped diagnosis because they were in a silent area of the peritoneum. The best illustration of this is the inflamed pelvic appendix, which may perforate and cause local peritonitis in the pelvis without any definite localizing signs. Such cases are not infrequently diagnosed only when the pelvic abscess causes intestinal obstruction. This mistake is prevented by an early rectal examination, for local tenderness is generally to be elicited. A similar difficulty may be found in the case of an appendix which perforates behind the end of the ileum. Umbilical and inguinal hernial sacs are usually sensitive, but the femoral hernial sac is usually silent.

The demonstrative part of the parietes localizes pain in several ways. The actual spot is tender on pressure, and usually gives rise to spontaneous pain. The neighbouring muscles are tender and often rigid, there may be hyperaesthesia of the skin, and contiguous viscera may be affected.

Painful rigidity of muscles almost always indicates inflammatory irritation of the underlying peritoneum, but absence of painful rigidity does not signify absence of peritonitis, for the muscles tire after a time. Rigidity is not usual in late peritonitis. Rigidity occurs not only in the lateral and anterior abdominal muscles, but also in the quadratus lumborum, psoas, and diaphragm. An inflamed appendix lying on the psoas may be localized by putting the psoas on the stretch by extending the thigh. Diaphragmatic rigidity causes immobility of the affected part of the diaphragm on respiration. Occasionally an abscess lying against the obturator fascia may lead to oedematous infiltration of the fascia and rigidity of the

obturator internus; this may cause pain when the muscle is put on the stretch by inverting the thigh in the flexed position. When an inflamed area is in contact with the iliac vessels this may be demonstrated sometimes by occluding the femoral vessels with the finger; the increased pulsation of the iliac artery causes slight pain owing to its contiguity with the parietal peritoneum.

Cutaneous hyperaesthesia is a more common accompaniment of parietal than of visceral irritation, though I cannot agree with the view that a viscero-sensory reflex does not exist. Peritonitis in the lower abdomen, whether arising from an inflamed appendix, an infected Fallopian tube, or other cause, commonly causes hyperaesthesia somewhere below the umbilicus and above Poupart's ligament; this hypersensitiveness is more common on the right side than on the left. A narrow band of hyperaesthesia is often found just above the right Poupart's ligament in cases of appendicitis, but the same band may occur with a perforated ulcer, and occasionally with cholecystitis, so that it is likely to be due to parietal irritation in the right iliac fossa.

Pain due to irritation of adjacent viscera may be of value in localizing lesions in the silent areas of peritoneum—thus pain in passing urine, associated with frequency, may call attention to an inflamed pelvic appendix.

The shifting of a pain is often of value in localizing the lesion. Severe epigastric pain followed soon by tenderness and pain in the hypogastrium indicates an upper abdominal perforation. Severe hypogastric pain followed soon by pain at the top of the shoulder should suggest lower abdominal haemorrhage. Epigastric pain followed in a few hours by definite tenderness in the right iliac fossa usually indicates appendicitis.

The third area of the abdominal parietes—namely, the diaphragmatic—is the most interesting and the most neglected of the three. Inflammatory irritation of the central part of the diaphragm causes no pain which is felt locally, but it commonly leads to a not very acute pain felt in the acromio-clavicular region on the same side of the body. This pain is, of course, easily explained by the fact that the descending acromial and clavicular branches of the cervical plexus come from the same segments of the spinal cord as the phrenic nerve.

My interest in phrenic shoulder pain began in Mesopotamia during the war. I found that liver abscess was only accompanied by pain at the top of the shoulder when the abscess was threatening to penetrate the diaphragm. From a study of these cases I came to the conclusion that it was the diaphragm, and not the liver, which was the source of the referred pain. This led me to investigate cases of gall-stones to see if the textbooks were correct in stating that pain was felt at the top of the shoulder in such cases. Here again I found that this shoulder pain only occurred when there was inflammatory change near the diaphragm; next I found that it was a common symptom in cases of perforated ulcer of the duodenum, and from this the generalization as to its significance was easy. Similar investigations were about the same time carried out in Germany, but I did not see these till my own views were formed.

The localizing value of phrenic shoulder pain is considerable, and hardly a week passes without my finding it of use; it often gives the needed clue in unravelling a difficult case. When an abdominal lesion is accompanied by pain in the supraclavicular, supraspinous, or acromial regions it will generally be found that there is inflammatory irritation of the diaphragm on the side of the pain. There is also a correspondence between the position of the irritation and the part of the shoulder to which the pain is referred—that is, irritation of the front and back of the diaphragm causes pain respectively in the clavicular and supraspinous regions. The pain is not usually severe; it is often thought by the patient to be a rheumatic pain, and may not be mentioned unless inquiry be made; occasionally, there may be accompanying hyperaesthesia. This pain must not be confused with the subscapular pain often felt with biliary colic and other lesions. At the time of its development in the early embryo the diaphragm is in the cervical region, and only later do the heart and lungs push it down to its subsequent position; the relative positions of the diaphragmatic lesion and its referred pain are better understood by imagining that the migration has not taken place. The localizing value of such pain would then appear obvious.

Phrenic shoulder pain is of localizing value in a great variety of conditions. In three out of four cases of perforated ulcer it is present at some time or other; sometimes it comes on simultaneously with the abdominal pain, but occasionally a few hours later. With perforated ulcer the pain is generally felt in the right supraspinous fossa and acromial region, but it may be felt at the back of the neck. The general statement may be made that sudden severe right hypochondriac pain accompanied by collapse and by pain felt on the top of the shoulder is almost always due to a leaking duodenal ulcer. Pain here is seldom caused by cholecystitis, and hardly ever by uncomplicated biliary colic. The legend that gall-stone colic gave rise to pain at the tip of the shoulder arose in the days when operative confirmation of the diagnosis was not forthcoming, and has been perpetuated in the usual slack manner of textbooks from generation to generation. The clinical simulation of the one condition by the other may be extremely close.

A man, aged 41, who suffered from indigestion of no definite type, was seized with sudden acute abdominal pain on September 28th, 1922, but improved a little afterwards. When I saw him four days later, there was a tender lump at the anterior border of the liver in the region of the gall-bladder. The main feature in the case, however, was the severe pain felt all over the outer and superior aspect of the right deltoid region. The patient said the pain was so severe that he could not lie on the right arm. I thought the condition was most probably due to an inflamed gall-bladder, but at the operation I found between the liver and the diaphragm an enormous collection of bilious fluid, which came from a perforation of the duodenum.

In making a wrong diagnosis here I went against my own experience that severe shoulder pain is much more often due to a perforated ulcer than to gall-bladder conditions.

Six months ago a woman, aged 50, was seized with violent upper abdominal pain with collapse, and pain on top of the right shoulder. When I saw her, four hours later, she looked and felt *much better, there was resistance and tenderness in the right* hypochondrium, but no tenderness anywhere else in the abdomen; again I diagnosed cholecystitis with biliary colic. Four days later when I operated I found a recently sealed-up perforation of the duodenum, with a normal gall-bladder.

A medical friend of mine rang me up urgently saying he feared he had gall-stones, because he had right hypochondriac pain and pain at the tip of the shoulder. He said he thought it was gall-stones because as a student he had been taught that shoulder-tip pain meant gall-stone disease. As a matter of fact he had diaphragmatic pleurisy, and no evidence of abdominal trouble, but the case shows how erroneous teaching on this point still may be.

Phrenic shoulder pain is also of value in sudden severe intra-abdominal haemorrhage. In a young woman of child-bearing age sudden collapse with hypogastric pain and pain on top of the shoulders should lead to the suspicion of a ruptured ectopic gestation.

With peritonitis of any origin top of the shoulder pain generally indicates that the infection has reached the diaphragm.

A patient who had had an operation on the rectum developed peritonitis, which proved rapidly fatal. The day before she died she complained of pains on top of the right shoulder, which puzzled those in attendance. When told of this symptom at the necropsy I advised inspection of the top of the liver, and there, as I expected, was found a great deal of inflammatory lymph, which by its irritation of the diaphragm must have caused the pain.

Finally, attention must be directed to the important fact that even with serious advancing lesions acute pain often tends to become less acute. This may result from several factors. In the first place the stimulus may be lessened by the dilution of toxins by effused fluid, by the rupture of a distended viscus, or by the gradual localization and limitation of the lesion. Secondly, although the peripheral stimulus may be undiminished, there may be a fatigue of the reflexes which cause some of the pains. Finally, in toxic states the sensorium becomes dulled, and the patient is then no longer in a position to appreciate pain as he was in the early stages of the condition. It is often very difficult to locate the diffuse and uncertain pains of late acute abdominal disease; and the moral of that hardly needs pointing out—diagnose early.

MODERN COSMETIC PREPARATIONS.

THEIR CHEMICAL COMPOSITION, AND THE PATHOLOGICAL DEVELOPMENTS ATTRIBUTABLE TO THEM.

BY

R. M. B. MACKENNA, M.A., M.B., M.R.C.P.,

HONORARY DERMATOLOGIST, LIVERPOOL STANLEY HOSPITAL.

THE notes from which this paper is composed were made approximately a year ago; they were not intended for publication, but for my own information. A short article on cosmetics in the *British Medical Journal* of February 8th[1] stated that "information that would be gratefully received by our profession" would be that "revealing the composition of face creams of various kinds, and other secrets of the toilet." This article has prompted me to write the following paper, which will, I hope, give some of the required information. For financial reasons it has been impossible to buy many of the expensive preparations mentioned, and to have detailed analyses made; many of the formulae are therefore taken from the *Book of Receipts*[2] and from other sources mentioned in the text.

COSMETIC TREATMENT OF THE FACE.

It is of some interest to consider the cosmetic treatment of the face, as recommended by many shops, and to subject this line of treatment to a brief analysis. The majority of "beauty specialists" suggest that soap and water should not be used, but the face should be "cleansed" (*sic*) by the application of cold cream; any surplus should be removed with absorbent paper or a towel, and vanishing cream should then be applied. The toilet should be completed by the judicious use of a powder, which may vary in hue from green or mauve to pink or tan. At night the face is "cleansed" with cold cream or similar application, and a lotion or a "skin food," or both, is applied, and in many cases the lady goes to bed with a thick coating of the latter covering her face.

The superstition that soap and water are bad for the complexion probably arose in the days when toilet soaps contained an excess of alkali, and therefore did tend to irritate the skin. Nowadays, when soap-making has almost reached its zenith, it is only in exceptional cases that the skin of the face is irritated by toilet soaps. A good toilet soap does not contain more than 0.25 per cent. free alkali, an amount which does not irritate the majority of skins. Superfatted soaps contain approximately 1 per cent. of lanoline, which has the effect of counteracting any irritation caused by free alkali, and these are the best soaps for toilet use. Soaps containing coco-nut oil lather well in hard water, but the oil has an irritating effect, and these soaps should be avoided. True Castile soap is made with sodium stearates and olive oil, and is a good soap, but many of the cheaper varieties are made with coco-nut oil, and may have a deleterious effect on the skin.

"Transparent soaps are made by adding to the soap alcohol or glycerin, or sugar, to an amount that prevents crystallization, and holds the soap in a colloid state. This in no way damages its quality. Transparent soaps are usually cold made and are apt to contain an excess of free alkali, for in its absence the soap will not maintain its brilliancy. The only way to avoid this is by dissolving the soap in alcohol and resolidifying it by evaporation of the alcohol—an expensive process—so that, as a rule, only the best transparent soaps are free from an excess of alkali."—PUSEY[3]

If the patient complains that soap irritates the skin, inquiry should be made as to what soap is being used, and a superfatted soap should be ordered. In exceptional cases any good shaving soap, which is the most highly superfatted soap readily obtainable, may be recommended for cleansing purposes.

Cold Cream.

The formulae of cold creams vary considerably. The majority contain borax, and the following may be taken as typical examples:

A.	
White wax	lb.j
Liq. paraffin	Oij
Almond oil	Oij
Heat until wax is melted, then add:	
Borax	3j
Water	Oj
Misce.	

B.	
White wax	3ijss
Spermaceti	3ijss
Almond oil	3xxj
Anhydrous wool fat	3j
Melt, and add:	
Borax	3ij
Water	3x
Misce.	

H. S. Groat[4] states that "of the many formulae of this next class (that is, cold creams with an almond oil base) the following gives the most universal satisfaction:"

Ol. amygdalae dulcis	77
Lanum	15
Paraffin	18
Cera alba	18
Sodii biborate	1.5
Liq. hydrogen perox.	1.5
Ol. rosae geranii	0.2
Aq. destillata	27
Ol. rosae	0.1
Misce.	

Despite the fact that Groat's observations were made in 1915, there are many creams on the market whose formulae are slight modifications of the above. Groat also gives the two following as common formulae for cold cream:

Petrolatum liq.	120	Ol. ricini	120
Cera alba	40	Cetaceum	60
Aq.	40	Cera alba	15
Sodium biborate	1.4	Sodium biborate	1.5
Misce.		Ol. rosae, Ol. amygdalae dulc.	aa q.s.
		Misce.	

He points out that "there is a noticeable difference between cold creams made with and those made without borax"; *the former are always "whiter and fluffier and* seemingly not as greasy as the others, due to the uniting of the borax chemically with the palmitate, stearate, or fatty alcohol of the hard and soft basis." He qualifies this statement by pointing out that these reactions will occur only when the solutions are both heated to above 120° F.

There is certainly a difference in the consistency of cold creams which contain borax and those which do not, but I am advised by two authorities in chemistry that it is improbable that any chemical reactions of importance take place during the manufacture of these cold creams: in their opinion the constituents enter into that complex physical relationship known as emulsification, but in some cases a small amount of boric acid may be formed by chemical interaction.

Vanishing Creams.

A typical formula for vanishing cream is the following, which is a modification of pasta hamamelidis (*B.P.C.*):

Stearic acid	3ij
Glycerin	3ij
Sodii carb.	3iij
Aq.	3x

Melt the stearic acid and add to the hot solution of glycerin and sodium carbonate. Keep on a water-bath for one hour, stirring frequently. Add a little water from time to time to make up loss by evaporation, transfer to a water-bath, and add gradually:

Solution of witch hazel	3iv
Otto of rose	mxxx
Extract of violet	mxxx
Rose water to	lb.1

Stir until thoroughly mixed.

In this formula the stearic acid will react with the glycerin and the sodium carbonate to form stearin and sodium stearate, whilst some 13 parts of free glycerin will remain. Sodium stearate is, of course, a soap, while stearin is, to all intents and purposes, tallow.

Many other formulae are in use, but the majority contain an excess of glycerin, and a few also contain soft or liquid paraffin. It is interesting to note that, of two formulae which came to my notice, one contained approximately a drachm of casein in every ounce of the cream, while the other contained a small amount of agar-agar.

Pathological Effects Attributable to Cold Cream and Vanishing Creams.

The probable and possible ill effects of the frequent application of the preparations detailed above may be classified as: (*a*) deleterious effects caused by the chemical nature of the ingredients; (*b*) deleterious effects caused by the physical properties of the ingredients. The reader is reminded that any remarks made under these headings refer to the prolonged use of the preparations. This reservation is justifiable, because once a woman has taken the trouble to learn a beauty treatment the routine is usually carried on daily for some years.

The deleterious effects caused by the chemical nature of cold creams are slight. The creams are merely mixtures of oils, fats, and waxes, but a certain percentage of cold

creams contain liquid paraffin, which is a mixture of liquid hydrocarbons. Crude paraffin is known to have cancer-producing properties, but there is no *direct* evidence to show whether or not liquid paraffin possesses similar deleterious properties. Any irritant effect which the cold creams possess is definitely intensified by the successive application of vanishing creams, for while the stearin and the sodium stearate have but little action except to form a waxy bloom of soap *plus* tallow on the skin, the glycerin is absorbed by the skin, and, being powerfully hygroscopic, must considerably upset the metabolism of the superficial cells of the epidermis. This action is intensified by the mildly astringent action of the hamamelis, which will tend to precipitate the proteins in any cell with which it comes in contact. The glands of the skin must perforce suffer more than the cells of the epidermis, as once the creams reach the lumen of the glands the chemicals exert their action on the delicate secreting cells. In this connexion it will be remembered that the majority of rodent ulcers commence in the sebaceous glands, and it will be interesting to note whether during the next twenty years there will be a steady increase in the number of cases of rodent ulcer and epithelioma of the face in women, and whether we shall see more neoplasms of this nature in young women than is at present the case. Some patients are surprisingly susceptible to boric acid, and even a small amount absorbed through an abrasion of the skin may cause an acute generalized vesicular or scaly eruption. The boric acid in cold creams may therefore be an unsuspected source of mischief.

The physical effects of the use of vanishing and cold creams on the face are considerable. First, with the exception of the glycerin, none of the constituents are absorbed. A fatty layer is therefore left on the skin, which gives a waxy "bloom" to the cheeks and hides any defects of the skin. This is the only cosmetic value which the preparations possess. The fats block the sebaceous and sweat glands. Perspiration is interfered with, and the control of the skin temperature by the evaporation of insensible perspiration, and also the conduction and convexion of heat, is retarded. This causes the temperature of the skin to rise, and leads to a continued dilatation of the superficial blood capillaries, and eventually to the production of acne rosacea. The slight increase in temperature may also stimulate the activities of the *Demodex folliculorum*, and also of the morococcus of Unna, and any other organisms which may be present in the sebaceous ducts; as the majority of these organisms are resistant to mild antiseptics, the boric acid, etc., has but little effect on them. The formation of comedones is thus facilitated, and acne vulgaris may develop, especially if the patient is between 17 and 25 years of age.

Applications which Act by Irritation.

Of the various other cosmetic preparations on the market we may refer to "wrinkle removers" and "skin tighteners." These are of two varieties. The first variety consists of relatively innocuous ointments which may contain lard or lanoline, or both, and which have to be massaged into the skin. Their action depends entirely on the fact that massage causes contraction of the underlying muscles, and the wrinkles are thereby smoothed out. Their efficacy depends to a certain extent on the vigour with which they are applied. The second variety consists of irritant applications, and the majority of them are pernicious, as they are used chiefly by women over 45 to apply to the periorbital area, which is one of the sites of election of rodent ulcer. Two typical formulae are:

Zinc sulpho-carbolate gr.xx	Alum ... ... gr.x
Zinc oxide 3vj	Zinc sulphate... ... gr.v
Glycerin 3ij	Glycerin 3j
Rose water 3v	Tincture of benzoin 3j
Elder-flower water to Oj	Ess. of Eau de Cologne mxxx
Misce.	Distilled water to ... Oj
	Misce.

These lotions act by irritating the skin so that a reflex contraction occurs in the superficial muscles, whereby the wrinkles are obliterated. The last state of the patient who employs these lotions is invariably worse than the first, as senile changes and atrophy of the muscle fibres are hastened, and the wrinkles deepen and cannot be removed.

Lotions.

Various lotions are sold for cosmetic purposes; the majority of them are open to the same criticism as vanishing and cold creams. The following formulae are of interest.

Glycerin and Cucumber Lotion.

Beef suet	3ij
Prepared lard ...	3iv
Powdered curd soap	3iij
Borax	3j
Distilled water ...	3xviij

Strain through muslin and add:

Glycerin	3vj
Rectified spirit ...	3ss
Otto of rose... ...	mv
Oil of ylang-ylang...	mj
Essence of cucumber	3iv

Misce.

Elder-flower Milk.

Bitter almonds ...	3jss
Borax	gr.xxx
Glycerin	3ij
Elder-flower water to	Oj
Oil of ylang-ylang	mv

Misce.

Milk of Roses.

Blanched almonds...	3ij
Blanched Castile soap	3ij

Make a paste and add, previously melted together:

Spermaceti	gr.lx
White wax	gr.cxx
Almond oil	3ij

Mix; dilute with water t 19 oz., and add one ounce o essence of rose.

"*Skin Foods.*"

Various ointments are on the market and are sold "skin foods." They exert an emollient action, and th skin is stimulated by the massage with which they a applied. They are not, of course, absorbed. Care taken that they are not greasy, as it is believed th "grease makes the hair grow." The following are typic examples:

Liq. hamamelidis	5j
Ung. althcae*)	
Ung. cetacei)	āā5j
Ung. aq. rosae)	

Misce.

White wax	5jss
Spermaceti	5jss
Coco-nut oil...	3j
Wool fat	5j
Ol. amygdalae dulc.	5ij

Melt, and add:

Orange-flower water	5j
Tinct. benzoin simplex	mxij

Misce.

Like cold cream, this form of ointment softens the superficial cells of the horny layer and gives the face a smoot soft appearance, but these ointments are obviously open the objection that they tend to produce acne rosacea a acne vulgaris, and this is especially so because the "sk foods" are usually applied at night and the patient slee with her face plastered with them. It will be noticed th the last preparation contains coco-nut oil, which is de nitely a skin irritant.

Treatment.

The physician who ruthlessly forbids the use of the preparations may find his patient returning reproachful to him with an itchy red dermatitis of the face and nec and, as this dermatitis clears up as soon as she reverts her favourite "skin food," her confidence in her physici is, naturally, shaken. The explanation of the matter obvious. The normal skin does require an emollient keep the horny layer from cracking and becoming "chapped." This emollient is normally provided by the sebum manufactured by the skin itself. If, however, the sebaceous glands are continually blocked for several years with external applications they cease to function, and if the emollient applications are stopped it may take some weeks before the glands recommence to secrete. In some cases they never recover, much to the benefit of the "beauty specialist." It is therefore advisable, at the outset, to warn the patient that she may have ruined the glands of her skin by applying cosmetics, and that she may have to continue to use various creams for the rest of her life; the treatment should commence by gradually discarding the use of cosmetics, in order to give the glands time to recover. A spirituous lotion of mercury perchloride may be used for a few days to remove all traces of fats

* Ung. althcae, marshmallow ointment—a herbal remedy.

from the skin, and, as the "beauty specialist" would say, "to cleanse the pores." I suggest the following:

Hydrarg. perchlor.	... ...	gr.1/6
Glycerin	... .	3ss
Surgical spirit .	... ...	3ij
Aq	... ... ad	3i

Misce.

This lotion should be used with caution. If the patient perseveres in her refusal to use cosmetics, and avoids exposure to direct sunlight and cold winds for about fourteen days, the skin will become normal in the majority of cases, and the vicious circle engendered by the routine use of cosmetics will be broken.

The present trend of fashion seems to be that a woman considers she is looking her best if her skin is covered with a translucent layer of greasy substance. If the teachers in girls' boarding schools would prohibit the use of cosmetics we would be able to produce a race of women whose complexions were as good as those of men, but at present the possibility of this eventuality seems very remote.

The Hair.

Much ingenuity has been shown in devising shampoo lotions for the hair. The majority of these are harmless.

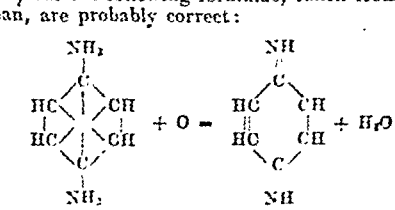
Hair-waving may be temporary or permanent. Either type of waving is comparatively innocuous, but as heat is employed in permanent waving fragility of the hair may result, and the patient may complain that the ends of the hair fray out, and that they break easily.

In regard to hair dyes: a considerable amount of research is being done by fully trained chemists in order to obtain a perfectly harmless dye which will be non-toxic to the patient, non-injurious to the hair, and which will "consist of two or three solutions of such a nature that, by adjusting the proportions of each, any and every possible shade can be produced."[4]

As nearly every English textbook of dermatology contains a phrase such as "the only duty of the dermatologist in regard to hair dyes is to warn his patient against their use," there is widespread ignorance in the profession on the subject. Before a dye is applied to the hair the sebum must be removed. This is usually done by washing the head, and thereafter applying an alkali—for example, sodium or potassium hydroxide or ammonia. If too much alkali is used a dermatitis of the scalp may occur, and the hair may be damaged. Leftwich[5] has shown that a solution containing 10 per cent. of ammonia decreases the tensile strength of hair by two-thirds, but that a solution containing 1.2 per cent. of ammonia has but little effect.

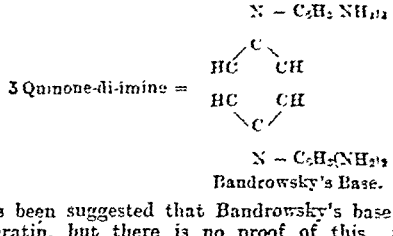
Dyes may be classified as being of two types: (1) those which are not absorbed into the cortex of the hair; (2) those which penetrate the cortex.

The first category includes kohl (antimony trisulphide), which was used by the Egyptians, but as the compounds of antimony are powerful irritants this preparation is no longer used. The modern form of kohl is finely ground carbon made up into a pencil with wax or paraffin. This is the common eyebrow pencil, and its use is obviously a dirty but innocuous habit. Iron sulphide is occasionally used to darken grey hairs. The hair is sponged with a solution containing ferrous sulphate; twenty-four hours later a lotion containing an alkaline sulphide—for example, $(NH_4)_2S$—is applied, and iron sulphide (FeS) is precipitated on the hairs. The alkaline sulphides have the property of dissolving keratin, and are used as depilatories; consequently, if the sulphide solution is too strong a regrettable accident may occur. A less nauseating but more dangerous way of obtaining the same result is by using solutions of lead acetate and sodium thiosulphate. It is obvious that if there are any abrasions on the skin there is a danger of absorption of the acetate, which, if the patient is pregnant, may have serious results. Lead dyes are usually sold as "hair restorers" for home use.



Silver dyes are also employed. They can be prepared to produce a range of shades from ash-blonde to black. The simplest method of employing these is to precipitate black sulphide of silver on the hair by the use of solutions of silver nitrate and alkaline sulphides. Another method consists in precipitating silver on the hair by the addition of a solution of pyrogallic acid to an ammoniacal solution of silver nitrate. This method is highly dangerous. Pyrogallic acid is a keratolytic, and is known to be able to cause a dermatitis in susceptible persons. An incidental disadvantage in the use of silver dyes is that some barbers use potassium cyanide to remove any traces of silver salts from the skin.

Dyes which penetrate the cortex of the hair include henna and the aniline derivatives. One can state emphatically that a pure henna dye is harmless. It produces an auburn colour, and is sometimes incorporated in shampoos. Many preparations on the market are mixed with aniline dyes, and are so compounded that any hue from light brown to black may be obtained. "Hennareng" is a mixture of henna with indigo, and is comparatively innocuous.



The Para-phenylene-diamine Dyes.

There now remains to be discussed a group of dangerous aniline dyes known collectively as "Para." These are used considerably, as they belong to the second category of dyes, and therefore are semi-permanent, and cannot be washed out. In addition, the hair may be waved after the dye has been applied, which for obvious reasons cannot be done after a precipitated "dye" has been used.

The dye of this class in common use is para-phenylene-diamine, which is generally used to dye the hair black. Para-toluylene-diamine and para-diamino-phenol are also frequently used in conjunction with para-phenylene-diamine to produce reddish, blonde, or ash shades. The exact chemical action of para-phenylene-diamine on the hair is unknown, but the following formulae, taken from Redgrove and Foan, are probably correct:

Para-phenylene diamine + Oxygen = Quinone di-imine + Water.

Bandrowsky's Base.

It has been suggested that Bandrowsky's base combines with keratin, but there is no proof of this. Schueller[4] has stated that quinone-di-imine is a substance which is toxic to the human skin, but that the pigment which is finally formed is non-toxic. Probably Bandrowsky's base is capable of causing toxic effects, because dermatitis of the neck occurs in susceptible persons who have worn furs dyed with these substances.

In order to achieve the oxidation of the para-phenylene-diamine the compound is mixed immediately before use with 15 or 20 volumes of hydrogen peroxide. Potassium dichromate, or potassium chlorate, mixed with a salt of vanadium is sometimes used as an oxidizing agent. To assist penetration of the hair a caustic alkali or ammonia is usually added. The dye is then applied to the hair by means of a brush, and approximately a quarter of an hour elapses before the correct colour develops. A wet shampoo is usually employed to remove any surplus dye.

So many accidents have occurred from the indiscriminate use of para-phenylene-diamine that the majority of barbers now employ a sensitization test, known as Sabouraud-Rousseau's test. The skin over the mastoid process is cleansed with alcohol, and the dye and its oxidant are applied. When the mixture has dried the area is covered with flexile collodion. After twenty-four hours the collodion is removed and the skin washed with soap and water. If the patient is sensitive to the dye a mild reaction will have occurred. Foan states that some of the leading French hairdressers advocate that this test should

also be made on the skin over the median basilic and internal saphenous veins, as experience has shown that some patients give a negative reaction behind the ear and a positive one over these last-mentioned areas. The probable explanation of this is that there has been some error in the application of the reagents to the skin behind the ear, so that oxidation has not occurred. A single application of the dye may sensitize a patient, and therefore the test should be applied on every occasion that the hair is dyed.

The toxic effects of para-phenylene-diamine may be classified as local and general. The local effects vary in intensity with the susceptibility of the patient and the form in which the dye is applied to the skin. For example, it is quite a common occurrence for a patient to come for advice with a blotchy erythematous dermatitis of the neck, and sometimes of the face, and to give a history that she tried on a series of furs in a shop. Half an hour later she noticed that her neck was itchy and red, but this soon passed off. The next day the fur was delivered, and in the full pride of possession she wore it for a short period. Within an hour or two the neck became red, itchy, and inflamed. In some cases vesicles form. The dermatitis arising from an hour's exposure to a fur dyed with "para" may, if untreated, last for as long as fourteen days. If the head has been dyed, and the patient is susceptible, an acute erythematous dermatitis of the scalp rapidly develops. Vesicles and bullae may form and rupture. The dermatitis spreads to the face and neck. The scalp may become "boggy" and oedematous, and periorbital oedema is a common occurrence. The patient commonly complains of headache, nausea, vomiting, and diarrhoea. The temperature may rise to 104°, and there may be a rigor. In very acute cases albuminuria occurs. These symptoms are due to two causes: (*a*) toxaemia caused by the acute dermatitis; (*b*) poisoning due to absorption of the dye.

The treatment is prophylactic (that is, avoid exposure to the dye) local, and general. In mild cases the dermatitis may subside if a simple calamine lotion containing 2 per cent. ichthyol is applied. In acute cases the hair should be cut as close to the scalp as possible, and calamine lotion with 1 per cent. ichthyol applied frequently on linen or gauze dressings, no oilsilk being used. It is most dangerous to attempt to remove the dye from the hair by the use of hydrogen peroxide or sodium thiosulphate, as these measures may only intensify the symptoms. I have found that the most efficient way of reducing the oedema of the eyelids is to use the following "drops":

R	Liq. adrenalin. hydrochlor.	mviij
	Sodii biboratis	gr.x
	Aq.	ad 3j

Misce. Sig.: Dilute with an equal quantity of warm water and use as "drops" for the eyes.

A third of a pastille dose of *x* rays will help to control the dermatitis. The general symptoms should be treated on the usual lines. As the majority of these cases result in legal proceedings, it is as well for the practitioner to ask the patient's permission to inform the barber who is responsible that an acute dermatitis has supervened, so that the case may be examined during the acute stage by the medical representative of the barber's insurance company.

Hair-bleaching.

Bleaching of the hair frequently precedes dyeing, for if the patient has had her hair dyed some months previously it is impossible to obtain a satisfactory coloration of hair which is grey in the proximal, green in the middle, and auburn in the distal thirds. The hair has to be made a single colour. Oxidizing agents—for example, sodium hypochlorite (which is sold as "eau de javel") and hydrogen peroxide (10 to 20 volumes)—are commonly used. The hydrogen peroxide is used in conjunction with ammonium hydroxide, as the latter removes sebum and also neutralizes any dilute sulphuric acid which may remain in the peroxide. Hydrogen peroxide has been shown by Leftwich[5] to have little, if any, deleterious action on the hair. Potassium cyanide and oxalic acid are both used as bleaching agents; their use cannot be too emphatically condemned.

Summary.

1. Various formulae for cold creams and vanishing creams have been considered and discussed. It has been shown that these may have an irritant effect on the skin, which may in time lead to the production of rodent ulcers and epitheliomata, and that these applications are prolific originators of comedones, acne vulgaris, and acne rosacea.

2. The formulae of irritant applications ("wrinkle removers") have been studied, and their effect in the production of neoplasms of the skin has been discussed.

3. Formulae for skin foods and lotions have been given, and a line of treatment for a skin ruined by the injudicious use of cosmetics has been indicated.

4. The hair dyes in common use have been briefly enumerated, special reference being made to the para-phenylene-diamine group of dyes. A brief account has been given of the signs, symptoms, and treatment of para-phenylene-diamine dermatitis.

It is my pleasant duty to acknowledge my indebtedness to Professor Dilling and Professor Hilditch of Liverpool University, and to W. E. de B. Diamond, Ph.D., for advice in regard to the problems in pure chemistry with which I have been confronted in the preparation of this paper. My thanks are also due to Mr. E. W. Lucas and Mr. H. B. Stevens for permission to publish formulae A and B and the formulae for vanishing cream, wrinkle removers, and the various lotions, all of which are taken from their *Book of Receipts*; also to Mr. H. S. Redgrove, B.Sc., A.I.C., and Mr. G. A. Foan, who have allowed me to make full use of their book *Blonde or Brunette?* the standard book on hair dyes and hair dyeing (Heinemann (Medical Books) Ltd.).

A CASE OF RUPTURED OVARIAN PREGNANCY.

BY

E. L. GRAFF, M.A., M.B., B.CH.CANTAB.,

LATE OBSTETRIC RESIDENT, GUY'S HOSPITAL.

THE case here recorded provides definite proof of a pregnancy occurring in the ovary. E. W. Riches,[1] in a recent publication, relates that "Lockyer, reviewing the literature from 1910 to 1917, found records of 22 genuine cases. Prior to 1910 there were recorded, according to a German estimate, 33 cases, and according to an American estimate only 19. Since 1917 a further 29 cases have been recorded

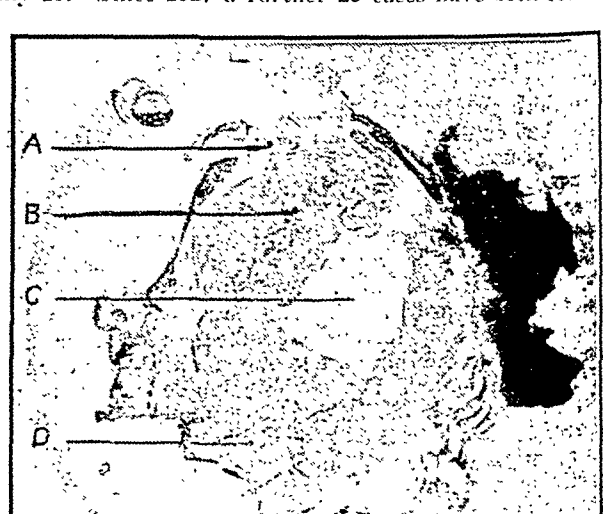

FIG. 1.—A, Corpus luteum; B, chorionic villi embedded in blood clot; C, amniotic cavity; D, blood extravasated through wall of cyst.

by various authors, making a total of 84 cases in all." This case, with Riches's, brings the total of recorded cases to 86.

N. A., aged 35 years, had had three previous normal pregnancies, her youngest child being 4 years of age. Her periods occurred at two- to three-weekly intervals, and lasted three days

A period finished on April 26th, 1928, and on May 26th she had a sudden attack of pain, simulating labour pains, in the hypogastrium and passing through to the back, and which lasted thirty-five minutes. Eleven days later, on June 6th, she experienced a second attack, which continued on and off for two days, gradually lessening in intensity till she came to Guy's Hospital and was admitted on June 8th.

On admission the temperature was 98.4° F., respirations 20, and pulse 105 per minute. The general condition of the patient was poor, the haemoglobin was 46 per cent. She complained of severe abdominal pain below and to the left of the umbilicus. On

FIG. 2.

pelvic examination there was *guarding of the abdominal muscles over the right* and tenderness in both iliac fossae. On vaginal examination the external os was found closed, the uterus was anteverted and normal in size and consistency. Through the right lateral fornix a *smooth lump the size of a tangerine orange* was felt in the position of the right ovary. A scanty clear watery discharge was present but there was no evidence of any uterine haemorrhage whatsoever. A diagnosis of ectopic gestation was made.

On June 15th the patient began to lose blood per vaginam; by the 18th however, her general condition had greatly improved, and the haemoglobin had risen to 64 per cent.

A laparotomy was performed on June 18th. On opening the abdomen through a right lower paramedian incision the peritoneum was found to contain blood clot which filled the utero-vesical pouch. The uterus, left ovary, and tubes were perfectly normal. Attached to the lateral half of the right ovary was a firm blood clot the size of a small tangerine orange. The ovary was cut across and the right half, with the attached blood clot, removed. The remaining clots were cleared out from the peritoneal cavity, and the abdomen closed without drainage. The patient made an uninterrupted recovery, and was discharged on July 9th.

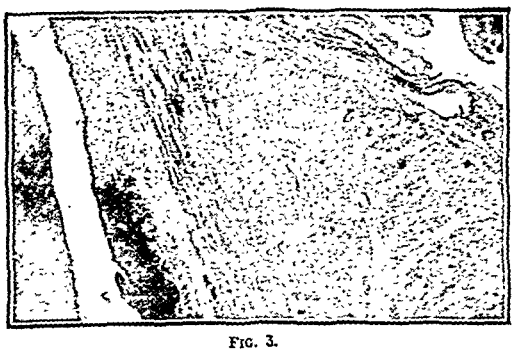

FIG. 3.

Description of Specimen.

The specimen consists of a spherical mass 5 cm. in diameter, and having half the ovary attached to its outer surface. This outer surface is for the most part smooth, and formed by a membrane in which ramify several small blood vessels. Showing through this covering is dark blood clot, and in one place (opposite to the ovarian tissue) there has occurred a rupture of the sac with haemorrhage on the exterior.

Examination of the cut surface (Fig. 1) shows quite definite ovarian tissue containing at its lower edge a recent corpus luteum. The luteal cells are thinned out over the mass of blood clot, which can, in fact, be aptly described as *haemorrhage* occurring into a corpus luteum cyst. In the centre of the clot is a somewhat irregularly shaped amniotic cavity filled with a homogeneous transparent substance, but unfortunately revealing no trace of any embryo. Dotted about in the blood clot between the wall of the sac and the amniotic cavity are several small white areas, and these, on microscopical examination, are seen to consist of typical chorionic villi (Fig. 2). Fig. 3 shows the characteristic arrangement of luteal cells and the wall of the corpus luteum in direct continuation with the wall of the cyst.

There seems to be no doubt from the specimen that this is a case of pregnancy following impregnation of a Graaffian follicle, and that the developing corpus luteum was thinned out by the growing sac. The two attacks of severe pain can be explained by a consideration of the specimen. The first doubtless occurred when the haemorrhage took place into the cyst and the gestation sac; the second when the distended cyst ruptured into the peritoneum.

I have to thank Dr. J. J. Conybeare and Mr. A. J. McNair for permission to publish this case, Dr. J. W. Shackle for preparation of the photomicrographs, and Mr. R. C. Brock for assistance in compiling the description of the specimen.

THE ADVANTAGES OF A PORTABLE THERMOSTAT FOR BLOOD TRANSFUSION.

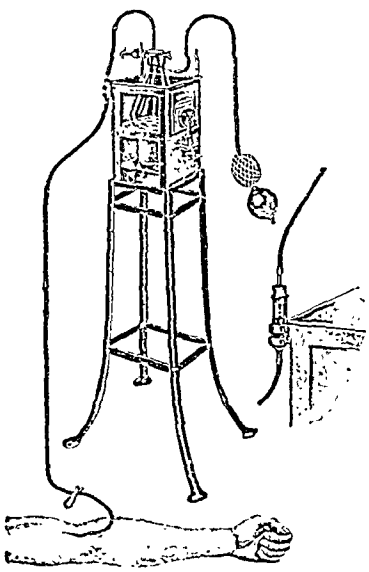
BY

GEOFFREY SHERA, M.A., M.B., B.CH.CAMB.,

CONSULTING PATHOLOGIST TO THE EASTBOURNE HOSPITALS AND TO THE EAST SUSSEX COUNTY COUNCIL.

REACTIONS after blood transfusion can be negligible, mild, moderate, or severe; they are generally regarded as unpleasant for the patient, but otherwise harmless unless due to some form of incompatibility, a contingency not, however, under discussion in this article. Whether a reaction after transfusion has any beneficial effect is a *moot point. Protein shock*, as we know from Vines's work,[1] does in fact shorten the coagulation time, and a brisk reaction after blood transfusion may act similarly. I know from experience that a single transfusion had a continued and most beneficial action in a case of purpura haemorrhagica in shortening the coagulation time and bleeding time and increasing the platelets, but this particular transfusion was unaccompanied by any appreciable reaction beyond a very short rigor lasting seven minutes and a rise of only 1° F. On the other hand, I have seen reactions so serious as to endanger life from the point of view of myocardial disturbance in splenic anaemia with haematemesis, in secondary anaemia, and in pernicious anaemia. After performing a number of transfusions I have come to the conclusion that these severe reactions, which are characterized by (1) pyrexia over 103° F., (2) a severe rigor lasting twenty minutes or longer, (3) myocardial disturbance, with arrhythmia and feeble pulse, requiring stimulants, and (4) prolonged after-sweating, were closely associated with failure to warm the blood sufficiently beforehand, and to keep it sufficiently warm during the transfusion. One case in particular impressed me in this way.

A man with very severe, sudden, and repeated haematemesis from duodenal ulcer required two transfusions on successive days. At the first, owing to the urgency of the situation and to help from assistants none of whom had ever seen a transfusion, the blood was kept far from warm; the result was a severe reaction, which was probably rather dangerous to the heart. On the next day, when a second transfusion was given, the blood was kept warm throughout the operation in warm water periodically and persistently renewed. The result was a reactionless transfusion with excellent results.



Reviewing my first fifty transfusions, I find a record of severe reactions mostly among the earlier ones, but no less than 20 per cent. showed severe rigors lasting twenty minutes or longer. In 4 per cent. there were severe and really dangerous cardiac disturbances after transfusion, associated with the rigors and prolonged for some hours afterwards. The onset of these reactions was thirty to forty-five minutes after the transfusion. Pyrexia over 103° F. occurred in 14 per cent., and prolonged after-sweating also in 14 per cent.

In practice, I found that to keep the blood at a proper temperature by adding warm water to the basin in which the flask was immersed and stirring continually was tiring to the nurses and time-wasting, necessitating the services of two people at least, sometimes more, since one became tired of holding the basin. Keynes[2] in his excellent monograph gives no very specific directions on this point, except that "the flask may be stood in a basin of warm water to keep it at body temperature." Inasmuch as, later on, he says that in certain cases—for example, of secondary anaemia, where there is a plethora of fluids—"a half to three-quarters of an hour must be occupied in giving 500 c.cm. of blood" (with which I entirely agree) —that is, forty-eight to seventy-two minutes for 800 c.cm. in a bad case—anyone who has had experience of blood warming in this way will realize the extreme irksomeness of keeping the basin at the right temperature for over an hour, not to mention the shifting of the flask, with the risk of bumping it against the basin—difficulties increased enormously in a private house.

Oswald Robertson,[3] in the classical report on "Wound Shock and Haemorrhage," commenting on this point, remarks, "the bottle is restoppered and placed in a glass jar containing water at a temperature of 106°-107° F. (41° C.). If the water is maintained at this temperature, and the bottle is occasionally agitated, the blood becomes warm in a few minutes." True enough, but keeping it at an even temperature is almost impossible by manual means with any degree of accuracy. It seemed to me, therefore, high time that a thermostat should be used —that is, an automatically regulated water-bath, such as is used in the laboratory for Wassermann tests, but adapted for this type of work.

The Thermostat.

With the collaboration of Messrs. Charles Hearson and Co. I have evolved a convenient thermostat or water-bath, which is easily portable; it is supported on a stand of the necessary rigidity and height. A collapsible stand has been, for the moment, ruled out, on account of the essential rigidity required. The stand can be introduced into the average car for transport quite easily, and the trouble of taking it to the bedside is well repaid by the convenience of having an anchor and support of just the right height.

My mode of operation is as follows. The blood is drawn into one flask and filtered into another through several thicknesses of gauze. This filtration eliminates any minute clots, which rarely, but dangerously, occur during even the best conducted bleedings. Meanwhile the thermostat has been either lighted, or the current has been turned on and the water warmed; it is a help to start with the apparatus half full of water at about the right temperature (42° C. or 107° F.). The bath has a transparent window, which is turned towards the operator, so that he can see the level of the blood. The flask is lightly clamped in, since otherwise it would rise up owing to buoyancy; the transfusion is not begun until the temperature remains constant at 42° C., which takes a few minutes. This temperature allows two degrees drop during the transit of the blood down the tube to the patient, and sufficient length of tubing is essential to comfort in working. The bath is remarkably constant, the operation of the thermostat being excellent, whether for oil or electricity. Oil is essential for general purposes and for random transport, but for installation in one building electricity is preferable. If the whole apparatus is in use when anaesthetics are being administered (a very rare occurrence, inasmuch as transfusions are usually given either before or after op tions) care must be taken to stand the apparatus away from the head of the patient.

Advantages of having a Thermostat.

1. One, if not two, assistants are dispensed with. whole transfusion can be carried out unaided if necessa
2. The blood is guarded from disturbance.
3. It arrives at the patient at the right temperat constantly throughout the transfusion, however long.
4. Reactions become negligible, assuming that the c test has been carried out properly; cardiac reactions abolished, pyrexia is reduced to practically *nil*, while ri are rare or absent, and are very mild if present.

In my experience, the case for the transfusion ther stat is so obvious as to be incontrovertible.

The apparatus is supplied by Messrs. Charles Hearson and of 27, Mortimer Street, W.1, to whom I am indebted for n help; and also by Messrs. Down Bros., St. Thomas's Street, S.

SEPTICAEMIA OF UNCOMMON ORIGIN.

BY

D. IVAN GRACEY, M.B., B.Ch.,

LATE MEDICAL OFFICER, MALAYAN MEDICAL SERVICE.

SEPTICAEMIA due to *Bacillus pyocyaneus* is of somew uncommon occurrence. Stitt[1] states that this organ has until recently been considered rather harmless, that this view can no longer be maintained, as it frequently the sole cause of middle-ear inflammatic intestinal disorders, cystitis, and possibly at times septicaemia. Park and Williams[2] conclude that, altho ordinarily but slightly pathogenic for man, it may, un certain conditions, as in general debility, become dangerous source of infection.

B. faecalis alkaligenes is a normal inhabitant of intestinal tract, and haematogenous infection due to t organism is rare. Stitt[3] mentions that it has been isola from a few cases which resembled typhoid fever. Castell and Chalmers[4] state that it may produce a fever resembl enteric, and that vaccines have been tried in a few ca but no definite results have been obtained so far. H Zinsser and Russell[5] quote a case of severe gastro-enter due to it, but add that it cannot be considered pathoge as a rule.

The following three cases, admitted to the Pen General Hospital, present some points of unusual interes

CASE I.

A male Anglo-Indian, aged 25, was admitted on September 1 1929, with a history of irregular fever for six weeks; he been treated in another hospital for one month, but had before he was well, and his condition had relapsed. His bl was there stated to be negative for malaria. On admission temperature was 99.4° F., and the pulse 90. The heart and lu were normal. The abdomen was flaccid, but showed no tension, and the spleen was not palpable. A blood film negative for malaria. The urine contained a faint trace of albu and a few pus and epithelial cells. *B. pyocyaneus* was gr in pure culture from the blood in forty-eight hours, but cultu of the stools, urine, and sputum were found negative five d later. The Widal reaction was negative.

Cough and profuse expectoration of greenish material occur two days after admission, accompanied by impairment of reson and crepitations over the right lower lobe of the lung. There w no rigors, but the patient complained of feeling cold and shiv Distension of the abdomen and enlargement of the spleen fingerbreadths below the costal margin appeared on the fifth with severe epigastric pain. The pyrexia continued for thirty- days before the temperature finally reached normal, the high point being 104° F. Constipation was a troublesome feature. testinal antiseptics, such as salol and dimol, and colonic irrigati with sodium bicarbonate or yatren, at different periods, seemed have no influence on the course of the disease; quinine also no effect. Easton's syrup, given as a simple tonic when temperature showed signs of abating, appeared to do some go The patient was discharged fit on November 7th.

CASE II.

A married Tamil woman, aged 26, was admitted on July 6 1929, with a history of fever and vomiting for three days, pain in the lower part of the left side of the chest; she had

amenorrhoea for six months. No cause could be found for the pain in the chest; the heart and lungs were normal, the abdomen showed no tenderness, and the spleen could not be felt. The temperature was 100.6° F., and the pulse 100. The blood was negative for malaria, and the urine contained a faint trace of albumin and some triple phosphates. The uterus reached just above the level of the umbilicus, and there was no vaginal discharge.

A premature male child, which only survived two hours and weighed 1 lb. 12 oz., was born five days later. The placenta and membranes were complete; the lochia were never offensive, and the uterus involuted normally. The temperature remained high, the pyrexia being sometimes continuous and sometimes intermittent. Rigors occurred at intervals. Metastatic abscesses formed in the right thigh and left side of the neck, and were incised. Pain was again felt in the lower part of the left side of the chest, accompanied by cough and expectoration. Dullness with diminution of the breath sounds was found, but this improved for a time with an expectorant mixture and the application of antiphlogistine.

On September 4th fluid was aspirated and found to be sterile on culture. A slight leucocytosis of 12,000 per c.mm. was present. Blood was withdrawn for culture on the same date, and *B. faecalis alkaligenes* was isolated. Intravenous injections of neutral acriflavine and colloidal iodine were given, and some improvement in the temperature and general condition was noted, but only for a time. Two weeks later the patient's condition became much worse, the temperature rising to 105° F.; blood culture was repeated on September 27th; *B. faecalis alkaligenes* was again isolated and a vaccine prepared. The Widal reaction was negative. On October 16th a dose of one and a half million organisms was injected followed after four days by a dose of two million. A moderately severe reaction occurred after the first injection, and definite improvement set in. The temperature subsided gradually, and remained normal after the second injection. The patient asked to return home, and was discharged well on October 26th.

Case III.

A mail European planter, aged 22, was admitted on July 21st, 1928 with a history of pain and swelling of the scrotum for four days accompanied by high fever; he strenuously denied any venereal infection. He had had a swelling of the right knee one week previously due to an injury at football, and malaria in 1927. On examination intense tenderness and marked swelling of the right testicle was found, and, to a less extent, of the epididymis the cord was much thickened and tender. There was no urethral discharge nor sore, and a prostatic examination was negative. The temperature was 102° F., and the pulse 92. Examination of the blood and stools was negative. The urine was alkaline and contained triple phosphates, but was otherwise normal.

There was continuous pyrexia, which subsided by lysis on the twenty-seventh day. An abscess of the testicle developed two weeks after admission, and was incised under general anaesthesia. The patient felt and looked remarkably well during the course of his illness, but headache, severe testicular pain, and obstinate constipation were all troublesome as regards treatment. Dimol and hexamine were administered, but did not seem to have any appreciable effect. When the temperature had subsided convalescence was uneventful, and the patient was discharged well on September 8th, 1928.

A direct smear from the urine showed no pus cells or gonococci, and culture for *B. coli communis* was negative. Blood culture gave a pure growth of *B. faecalis alkaligenes* on July 22th, and the same organism was isolated in pure culture from the pus of the testicular abscess. The Widal reaction was positive to *B. typhosus* 1 in 200 on August 8th, and one week later showed a reduction in titre to 1 in 50. As the patient had not been inoculated against enteric this may have been due to group agglutination. The Wassermann reaction was negative.

The infection in the first patient almost certainly had its origin in the intestinal canal, and was severe and prolonged for such an organism. The second case was interesting owing to its extremely lengthy course, the isolation of the organism concerned on two separate occasions at over three weeks' interval, and the remarkable response to vaccine treatment. Infection, evidently, had been sustained prior to admission. In the case of the third patient the most striking feature was his excellent general condition throughout, in spite of a fairly severe infection. An opportunity was afforded of examining him recently, and no atrophy of the testicle was found.

I have to thank Dr. H. O. Hopkins, Government Pathologist, Penang, who carried out the laboratory investigations.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A POSSIBLE CASE OF PSITTACOSIS.

In view of the recent outbreak of psittacosis the following case may be not without some interest.

On February 16th I was called to see a young woman, aged 32, who had been taken ill five days previously with a rigor and a sudden blinding headache, and went to bed. She was extremely prostrated, and vomited several times. Hoping she would feel better, she rose on February 14th, but grew worse, and went to bed again. When I saw her she was very ill. She then had a short, dry, persistent cough, a headache which she described as agonizing, a sore mouth, the tongue covered with thick, brownish fur, a slightly sore throat, and complete anorexia. Her face was of a peculiar yellowish pallor, eyes sunken and half shut, expression dull. The reflexes were sluggish. There had been no epistaxes, the spleen was not enlarged, and there were no adventitious sounds in the lungs. The abdomen was slightly distended; constipation was a prominent feature from the beginning, and she complained of a slight ache in the lumbar region. Insomnia was very troublesome, and remained so until late in the illness. The urine showed nothing abnormal. The temperature was 103° F., the pulse only 90, and the respiration rate normal. The temperature, pulse, and respiration ratio remained practically constant throughout.

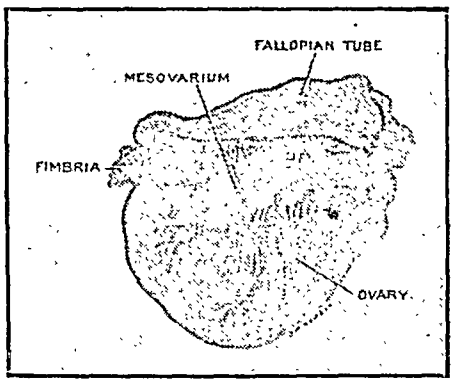
I suspected typhoid fever, and on making inquiries as to whether she was a contact I found that she had been nursing enteric cases in Las Palmas for the past three years. She said she had only returned to England a fortnight previously, and added that she had been immunized against typhoid and paratyphoid A and B. Further questioning elicited the information that during the voyage home she had had a pet parrot in her cabin with her, and had fed and kept it clean herself. No mouth-to-beak feeding had taken place, but the bird used to perch on her shoulder; it was reported to be in good health. Agglutination tests for the colon-typhoid group on February 17th were negative in all dilutions. In view of the patient's statement about immunization, this was surprising, but it turned out that, as is common in Continental countries, she had taken the immunizing substance orally, this producing local immunity in the bowel only, and not forming agglutinins in the blood.

She grew steadily worse, was collapsed and weak, and intensely depressed. On February 19th the headache was slightly better, but the patient was so weak that she could hardly move her head on the pillow, and she seemed slightly confused mentally, taking an appreciable time before answering any question. On the same day she complained of a slight pain in the left side; the chest, however, was still clear, though the cough was as troublesome as ever, and the spleen was not palpable. On February 20th the headache was better still, but she seemed even weaker, and had developed a mask-like facies. In the evening Dr. S. C. Dyke, honorary pathologist at the Royal Hospital, Wolverhampton, was kind enough to see her with me, and found a small, dull patch at the right apex, and some crepitations could be heard. Pain in the left side was now marked, but the spleen was still not palpable. He considered the case extremely suggestive of psittacosis, but as the bird, which had been left in Liverpool, was perfectly healthy, and in view of the marked toxaemia and collapse, he suggested a possible apical pneumonia, and took blood to see if a count would confirm the finding. The white count was as follows, however, practically putting pneumonia out of court. *Total white count:* 9,100 per c.mm.; *differential count:* polymorphs 65 per cent.; lymphocytes 29 per cent.; monocytes 5 per cent.; eosinophils, none seen; basophils 1 per cent.

On February 21st the headache had gone, the temperature was down to 99° F., the dull patch at the right apex had decreased in size, and the spleen was now palpable and very tender. The improvement continued, the temperature falling by lysis, and by February 23rd the dull patch at the right apex had disappeared, the cough, which had been unproductive throughout, became much better, and the spleen was no longer palpable, though there was still tenderness in the left side. Dr. Dyke saw the patient again on February 24th, and expressed the opinion that, clinically, it was a clear-cut case of psittacosis, even though the parrot remained healthy. Agglutination tests repeated on February 27th were again negative. The temperature was subnormal on March 3rd, and did not again rise above normal, but convalescence was long-drawn-out, and marked features were profound depression, a mask-like, Parkinsonian expression, and a persistence of the furring of the tongue till late on.

I regret that I could not get permission to have the parrot in the case examined, but the question arises. Is it possible for an apparently healthy bird to be a carrier of the disease? I understand that some success has followed the injection of the serum of persons lately inoculated with T.A.B. vaccine, in cases of psittacosis, but I was unable

to find such a person, and treatment was merely symptomatic. I should be interested to know, however, if this means that persons who have had T.A.B. inoculation are themselves immune to psittacosis. If so, my patient has cause to regret her merely oral immunization against typhoid fever.



My thanks are due to Dr. Dyke for his help and his great interest in the case.

Wolverhampton. A. V. RUSSELL, M.B. Ch.B.

TWISTED OVARIAN CYST IN A CHILD.

THE occurrence of torsion of an ovarian cyst in a child aged 8 is sufficiently rare to justify its being recorded.

The history of the onset is curious. During the evening of December 6th, 1929, a thunderstorm occurred. The child, being frightened, knelt on a couch and hid her head under a pillow, thus being practically in the genu-pectoral position. Immediately she rose from this position she felt a sharp pain in the left side of the abdomen in its lower half. The pain continued throughout the night; it was aching in character, and severe enough to

interfere with sleep. The next day she was kept in bed, and after vomiting three times felt better. However, the pain shortly returned, and commenced to pass across the abdomen from left to right in spasms, a little below the level of the umbilicus. The aching pain was present between the spasms.

On the third day the pain became localized at a point opposite the pelvic brim on the right side. On the same day pain was felt also at the end of the act of micturition, and continued up to the fourth day, when the patient was seen. The bowels were opened daily without any difficulty or pain.

Four days after the commencement the temperature was 100.8° F., the pulse 126, and the respiration rate 22. The lower half of the abdomen moved very little with respiration, and there was rigidity and tenderness here, more marked on the right side than on the left. The most tender spot was opposite the pelvic brim, low down on the right side. The urine was normal. A rectal examination was not performed. A diagnosis of acute appendicitis with pelvic abscess was made, and the child was operated on at once.

The abdomen was opened through a short paramedial incision below the umbilicus, and on passing two fingers into it a tense cystic swelling the size of a large hen's egg was felt in the left side of the pelvis. This proved to be a left ovarian cyst, which was twisted twice in a clockwise direction, and was bent over towards the right side of the pelvis. The pedicle was very broad, consisting of the broad ligament and Fallopian tube. The cyst, Fallopian tube, and the greater part of the broad ligament were quite black and becoming gangrenous. After undoing the twist, the cyst was easily delivered from the abdomen, and it was removed together with the gangrenous pedicle. The appendix was then excised and the abdomen closed without drainage.

The child made an uninterrupted recovery, the temperature becoming normal by the end of the second day. She was discharged fourteen days after the operation.

There are several unusual features about this case. The first of these is the early age of occurrence; then there is the unusually broad pedicle and the fact that it was gangrenous. Another interesting feature is that the greatest pain and tenderness were on the right side of the abdomen, which, taken in conjunction with the history, exactly simulated acute appendicitis.

I wish to thank Sir Arthur Keith for his kind assistance, for the drawing of the specimen, and for his permission to use it. The specimen is now in the museum of the Royal College of Surgeons.

County War Memorial Hospital.

Reports of Societies.

MENTAL FACTORS IN ORGANIC DISEASE.

A MEETING of the Devon and Exeter Medico-Chirurgic Society was held on April 24th, with the vice-presiden Dr. J. R. HARPER, in the chair. The president, Dr. F. ROPER, read a paper on possible mental factors in organ disease.

Dr. Roper described a case of encephalitis lethargi under his care; the patient, a child, besides having be under medical observation from the time of the illne eight years ago until the present, had also been close investigated by a psychologist. One of the conclusions the exhaustive report by the latter was that "though may appear to the medical mind a heresy to suggest i yet on psychological grounds it would appear that th unhappy child took flight into encephalitis lethargica an expedient to escape from an intolerable situation. In the examination of the problem arising from th finding—the particular problem of encephalitis lethargic and the general problem of the possible influence emotional states in determining susceptibility to oth infections—Dr. Roper cited other cases from his experien which appeared to be on the borderline between t functional and the organic, and others plainly organ where, however, an emotional basis seemed extreme probable. The recent monograph by Newsholme on th subject also included many cases of these types, and t views therein contained, though highly speculative a accordingly put forward with appropriate diffidence, y opened up a vista of increased knowledge if the tests future experience should substantiate them. Persiste mental strain, especially if firmly controlled, must le eventually to fatigue phenomena, in the first place fatig of nervous tissue. If sufficiently prolonged or severe su strain might render certain changes irremediable whi at an earlier stage were fully remediable. Moreove apart from direct stimuli from nerve cells under the conditions, there were the possible effects on the rest the body tissues, both neural and somatic, of the produc of the katabolism of such cells carried to them by t blood stream. When the nursing mother was under t influence of mental strain her milk was modified, an according to some, even rendered toxic, so, similarly, mu all secretions, such, for instance, as those of the nasopharyn and often of the alimentary canal, not to mention t tissues themselves, be changed. Levaditi found that t virus of encephalitis lethargica was present in an atten ated form in the nasopharyngeal secretion of certa perfectly healthy subjects. This virus in a more virule form could attack deeper structures of epiblastic origin, f instance the brain. Was it not possible that the chang in nerve cells under strain not only rendered them mo liable to attack, but by their effects on the quality of t nasopharyngeal secretion rendered possible the exaltati of a pre-existing saprophytic virus into a virulent strai capable of attacking the immediate subject and of infecti others with similarly weakened barriers? Apart also fr these considerations of infection the work of d'Here and Twort had indicated that if cells were attacked und certain conditions by bacteria they could react by splitti off a living entity—an "enzyme" or "bacteriophage perhaps—capable of propagation and transmission. If su bodies were produced by bacterial attack, could not oth intimate attacking agents such as, in the case of ner cells, severe emotional strain, conceivably bring about like result? Dr. Roper thought that such inter-reactio between the soil and seed, as well as actual events a factors, of nervous origin and largely resulting from t individual's make-up, were not only possible, but probabl further arguments from epidemiology were adduced su porting the hypotheses. On some such lines as these might be hoped eventually to bridge the gap betwe medicine and psychology, for most psychological scho nowadays postulated a biochemical basis for even the fin mechanisms of mind. The *mens sana in corpore sano* w only a partial statement unless it implied equally *corp sanum in mente sana*.

Dr. J. R. HARPER said he had seen a considera

number of cases of encephalitis lethargica, but the majority had been of a mild nature, and no notes on the condition prior to infection had been obtainable. He described a case where Parkinsonian symptoms had developed two years subsequently to a fracture of the skull. He also quoted cases where the physical signs had cleared up entirely after the acute stage, and raised the question as to what period of time must elapse before the child could be said to have escaped the risk of Parkinsonian sequels. Dr. R. WORTHINGTON recalled the novel of the Victorian era in which the hero, or heroine, was so frequently struck down by "brain fever" at a moment of intense crisis. Although the advances of pathology and bacteriology had tended to ridicule emotional disturbance as a factor in the production of inflammatory reaction, nevertheless it was possible that there was some justification for the earlier beliefs. Dr. Worthington added that apparently the lesions produced by influenza opened this gate to the virus of encephalitis lethargica, and he asked Dr. Roper if he intended to lead up to the view that depression of nerve tissue might invite the virus from healthy tissues, and thus cause injury to the brain. For example, a blow on the head might bring about loss of vitality, and permit a staphylococcus to gain entry in the same way as osteomyelitis could be originated in the long bones by trauma. Could mere psychological depression act in the same way by preparing the soil so that a virus could attack nerve tissue? Dr. SOLLY commented on the comparative immunity of the general public to infection either by the meningococcus or the virus of encephalitis lethargica. The virus concerned in the encephalitis which followed *small-pox might be*, not a direct influence, but rather a stimulator of the causal agent of the infection. Dr. G. I. THORNTON mentioned the possible association between varicella and herpes zoster, the latter so frequently occurring during an epidemic of the former as to demand an explanation other than that of mere coincidence. In view of the recent cases of encephalitis reported as following vaccination, and the similarity in the lesions of varicella and small-pox, Dr. Thornton asked Dr. Roper if he had personal experience of the herpes association—a definite expression of nerve implication, and hence important in this connexion.

Dr. ROPER replying, said that Dr. Worthington had interpreted his views correctly as regards a psychological factor in preparing the way for the entry of virus. He had not had sufficient experience of encephalitis lethargica to express an opinion as to the question of the stage when immunity from symptoms could be guaranteed in any given case. From his own experience he was able to quote cases where mere coincidence could not explain the association of herpes during an epidemic of varicella.

PRESERVATION OF THE EYESIGHT.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society, on May 1st, with the president, Dr. W. BARRINGTON PROWSE, in the chair, Mr. C. H. BRYANT read a paper entitled "The common-sense care of the eyes."

Mr. Bryant opened by remarking that regulations provided for the systematic testing of the eyes of school children, the establishment of clinics for the treatment of minor ailments, the supply of goggles for workers in dangerous trades, and regulations for the effective lighting of workshops. The approved societies administered "ophthalmic benefit" to those certified by panel practitioners as requiring glasses. Children often showed marked optical inequality, which might be the result of trauma *in utero*, caused by the cord or foetal fists. Injury by forceps at birth should not occur, but it was not uncommon; injuries after *birth might* be avoided by the nails *being kept short*, since infants had a habit of clawing their faces. Mr. Bryant strongly deprecated the excessive looking at picture books while children were in the nursery stage, as he was of opinion that this accounted for a large number of the children who were found to be myopic when they attended school. Squints could also be attributed to this, and pictures should be placed on the nursery walls and ceiling. Squint was a surgical emergency because, if untreated, it frequently resulted in one eye becoming amblyopic. The speaker said that children should be taught the alphabet as soon as possible so that their vision could be tested; any who showed a tendency to myopia should be educated *viva voce*, and not be allowed to read; he also advocated education by means of the cinema and gramophone, which offered great possibilities. The common custom of sending the boys out to play games and then, when tired, being put to two or three hours' work, often in winter in artificial light, was deprecated from the educational point of view, and also as being very dangerous for the eyes. Myopia was incurable, and condemned the patient to wearing glasses all his life; it was advisable that optical defectives should consult a specialist before deciding on an occupation. Myopes were liable to retinal detachment, but this was rare under the age of 20, and infrequent in both eyes. Feeble illumination and faulty positions were often responsible for nystagmus and vertigo. Many modern incandescent lights and fires emanated rays which irritated the eyes, and some protection should be afforded. Even in adults bodily debility increased the liability to myopia when the eyes were excessively used for near work; for this reason bedridden invalids should not be allowed to read or do needlework too much, and it should be borne in mind that spectacles did not prevent the wearer from becoming more myopic. Glasses should fit well and be worn straight. Town dwellers would probably avoid styes, meibomian cysts, and conjunctivitis if they habitually used an eyewash, antiseptic drops, or ointment. Goggles, being a complete protection from most common eye injuries, should be worn more generally in dangerous occupations.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this society on May 1st, with the president, Dr. CHARLES FORBES, in the chair, collections of recent pathological and anatomical specimens from various university departments were demonstrated. Dr. R. D. LOCKHART exhibited a series of dissections to show the comparative anatomy of the larynx, nasal cavity, and palate in man (foetal and adult), the seal, horse, sheep, dog, and cat, paying particular attention to the varying degree of coaptation between the epiglottis and the palate. He also showed a detachable model of the larynx, consisting of fifteen separate structures, to illustrate anatomical details and relations of importance in operative procedure. Mr. I. J. CUNNINGHAM presented a series of specimens of the intestinal tract of rats obtained during nutritional experiments on these animals fed solely on cow's whole milk and traces of metallic elements. After the animals had lived and grown on this diet in apparently normal fashion for a few months a considerable increase in the size of the stomach and caecum was noted. It was suggested that the greatly increased bulk of food necessary to support growth caused this adaptation in the gastro-intestinal tract: the condition was observed so regularly that it seemed probable that some relation between the size of the stomach and caecum to the bulk of food could be established by definitely planned experiments. Comparison of the specimens with the gastro-intestinal tract of normal animals demonstrated the degree of hypertrophy in the stomach and caecum. Dr. JOHN GRAY demonstrated two specimens of carcinoma of the thyroid gland. In one case the neoplasm arose from aberrant thyro-glossal tissue and had invaded the left vagus nerve. He then exhibited a specimen of congenital aneurysm of the base of the brain where there was evidence that the earliest haemorrhage had caused pressure on the third left cranial nerve. The first clinical sign in the case had been paralysis of the muscles of the left eye. Death had been due to extensive subarachnoid haemorrhage. Four specimens of cerebello-pontine angle tumour were also exhibited; in their symptomatology, defect of vision had been an unexpectedly early and marked feature. Professor ALEXANDER LOW showed the upper extremity of a recently discovered prehistoric skeleton where some pathological processes had resulted in synostosis of the radius and ulna. The ulna included the capitulum in its articulation with the humerus. Dr. ALEXANDER LYALL described a rapid and simple clinical method for the estimation of blood sugar. To 1.8 c.cm. distilled water in a test tube, 0.2 c.cm. blood was added, followed by 1 c.cm. picric acid, and the whole was shaken and filtered. The filtrate was made alkaline with 0.15 c.cm. of a 10 per cent. solution of sodium hydroxide, and boiled. The depth of the resulting red picramic colour could be estimated colorimetrically, and the blood sugar value read from a scale. Dr. Lyall demonstrated the method with specimens of normal and diabetic blood, and said that results by this method compared favourably with those found with the usual laboratory methods. An estimation of this type could be quite easily carried out where no laboratory aid was available.

Reviews.

PERNICIOUS ANAEMIA.

OWING to the recent great advance in the treatment of pernicious anaemia, the book[1] recently published by Dr. DAVIDSON and Professor LOVELL GULLAND of Edinburgh is very welcome. The discovery of "liver treatment," which must always be associated with the name of Whipple from the physiological side and Minot from the practical side, does not really represent a sudden break through, but the culmination of a steady attack from many sides on this very interesting disease and others which resemble it. It is for much more than the complete exposition of the new treatment that this book can be read with profit, since the whole story of slowly advancing knowledge in the past years is set out in perspective.

Pernicious anaemia is a disease which has always been of absorbing interest to clinicians ever since its original description by Combe, Addison, and Biermer. This was long before, as may be justly emphasized here, the discovery by Ehrlich in 1881 of the methods of staining blood cells, which founded the new science of haematology. So complete has been the revolution brought about by Ehrlich's staining methods that medical students, until very recently, could scarcely think of blood cells except in terms of the stains of Jenner, Leishman, or Giemsa. It is fortunate that the new methods of Doan, Cunningham, Sabin, and others have brought us back to the study of living and unstained or supravital stained cells, and in the book under review the drawings of Capell bring out the value of these newer methods clearly. With the development of Ehrlich's staining methods the histology of the whole haemopoietic system was systematically explored, and the different types of "red" and "white" cells were differentiated and given names. Thus the blood picture and the changes in the bone marrow in pernicious anaemia were gradually worked out. The part of the picture which gave rise to most discussion was the characteristic erythroblastic reaction of the bone marrow, and two schools disputed whether this reaction represented merely a great proliferation of normal red cells in response to urgent demand, or a definite disease or abnormality of the bone marrow itself. It soon became realized also that blood destruction, as proved by deposition of haemosiderin pigment in the liver, spleen, and kidneys, was an essential feature of the disease.

All these historic points are dealt with fully by the authors, and the work of Dr. William Hunter is very rightly given due credit. Hunter made one mistake, which it is easy enough to correct now, although this in no way detracts from the merit of his experiments. More recent work has shown that when blood destruction is induced experimentally anywhere in the animal body, haemosiderin is deposited chiefly in the liver, spleen, and kidneys. The sites of the haemosiderin deposits in pernicious anaemia do not therefore prove that the blood destruction occurs in the gastro-intestinal or portal tract, although they are not contrary to such a possibility. The authors deal fully with the importance of recent work on the products of blood destruction, and particularly with the question of bile pigment metabolism. It is now fully recognized, with the help of the van den Bergh reaction, that the lemon-yellow colour of the skin in pernicious anaemia is a real but latent jaundice, and during the active stages of the disease the van den Bergh reaction is always positive. With all these points cleared up an attack on the various aspects of the disease began anew. A notable advance in diagnosis, at first slowly realized by clinicians, but now come into its own, was the work of Price-Jones on the measurement of the diameters of red cells, and the development of his now well-known "curves." With this, and other methods of analogous kind, many doubtful diagnoses may at once be cleared up. Another point of diagnostic importance in pernicious anaemia is also well considered by the authors, which is fortunate, because many clinicians are still unaware of it. This is the marked "shift to the right" in the Arneth count of the polymorphonuclear leucocytes, and this work is largely due to Cooke of Wigan. In pernicious anaemia the number of polymorph leucocytes containing nuclei with 3, 4, 5, or even more lobes, is much higher than in normal blood, but it must be noted that this phenomenon occurs in sprue and a few other diseases.

It is impossible to deal in detail with all the eleven chapters in this book, and it would be invidious to try to find faults. There certainly exists no more complete account of the disease. The authors have wisely drawn their illustrations, many of them in colour, from well-known workers on various aspects of haematology, including Cooke Cappell, Cooke, McCluskie, Muir, Piney, Price-Jones, and Sheard, and the result is admirable. The book is so complete that every physician must profit by reading it, and its price (25s.) is reasonable.

BESREDKA ON IMMUNITY.

Immunity in Infectious Diseases[2] consists of a collection of reviews or studies on a variety of subjects, all more or less bearing on the subject of immunity, which Professor BESREDKA has published from time to time, principally in the *Bulletin* of the Pasteur Institute. The science of immunity is still in the early stages of its evolution, and in consequence, as the author points out in the preface, anything in the nature of a didactic treatise on the subject soon becomes out of date—in fact, it may even be so before it is published. Perhaps that is the reason why none of the essays here reproduced have been brought up to date, but it does not seem to be a very good one. Had these studies represented the evolution of an idea there might have been some excuse for the policy adopted by the author; but they do not, and it is hard to see what value a discussion of such a subject as "One streptococcus or many" can have which was written in 1904 and contains no reference to subsequent work, or a chapter on streptococcic serotherapy which only takes account of work published prior to 1909. The same applies to the other chapters which, with the two already mentioned, form the first half of the book. The rest of the volume is made up of Professor Besredka's more recent contributions to the subject of immunity: sensitized vaccines, oral immunization against typhoid and dysentery, the function of the skin in infection and immunity, and immunization by the cutaneous route by means of culture filtrates (antivirus). Much of this work is familiar not only to immunologists, but to clinicians also, for the use of antivirus, particularly in the treatment of coccal infections, has been a much-discussed subject in medical journals of late. Besredka's views have not met with general acceptance, and in this country the therapeutic use of antivirus has proved of little or no value in the hands of the majority who have tried it. It is true that he is able to cite a wealth of clinical evidence, coming very largely from the Latin countries of Europe, testifying to the efficacy of this form of immunotherapy, and Chapter X contains some illustrative examples. But we may be pardoned, perhaps, for thinking that some of the observations are more the outcome of enthusiasm for the method rather than a critical trial of it.

The translation leaves here and there a good deal to be desired. It is frequently too literal, and is marred by such terms as "anticolytic," which can only be understood by reference to the context. One does not speak of haemolysins being "paralysed" by serums, or of "acting on microbes with substances as anodyne as possible," though what is actually meant may be guessed. In one instance a doctor suffering from a boil on the nose, and who had tried the effect of a local application of antivirus overnight, noted next morning that his nose was no longer "incandescent"; one can imagine his relief. This book may be of some service to those who are already well grounded in the subject of immunity, and wish to acquaint themselves with Professor Besredka's views, but to the beginner it could be of little value.

[2] *Immunity in Infectious Diseases.* By A. Besredka. Authorized translation by Herbert Child, M.R.C.S., L.S.A. London: Baillière, Tindall and Cox. 1930. (Demy 8vo, pp. v.i + 364. 18s. net.)

CHEMICAL ASPECTS OF IMMUNITY.

IN preparing the new American edition of *The Chemical Aspects of Immunity*[1]—one of the series of monographs published by the American Chemical Society—the author, Professor GIDEON WELLS, follows the arrangement of the first edition published in 1925, but adds a full account of the work done during the past five years. The subject-matter dealt with in this monograph—the physico-chemical laws that govern the immunity reactions—bristles with intricate problems, and, though these are occupying workers all over the world, progress is necessarily slow. In every growing science there is a need for periodic stocktaking; facts gathered rapidly over a wide field may soon get out of hand. The value of Professor Wells's monograph is that it clears the way for further progress by assembling the established facts in an orderly and logical manner.

Among the problems on which new work has been done may be cited the influence of lipoids and carbohydrates on antigenic activity and specificity, and the manner in which antigens may be modified by chemical reagents. Progress has been achieved also in the purification of antigens and antibodies, and Professor Wells records some remarkable quantitative results. For example, purified diphtheria toxin has been obtained of which the minimum lethal dose for a guinea-pig is 0.28 microgram. Similarly, a unit of antitoxin appears to consist of a fraction of a microgram. A unit of haemolysin in pure state is only a few micrograms. Even these figures are eclipsed by those obtained in anaphylaxis, for this condition can be induced in a guinea-pig by 1/20 microgram of cristalline egg albumen. These figures are interesting and significant because they indicate one of the chief difficulties of the subject. The quantities of active substance involved are so infinitesimal that it is seldom possible to say whether an action which is produced by a substance that appears to be chemically pure may not be due to a trace of impurity present in quantities far too small to detect by chemical means. Those who are impatient at the slow progress made in elucidating the fundamental processes in immunology should remember that workers in this field have to deal with systems far more complex than those studied by the physical chemist.

"BORDERLINE" RAYS.

THE English translation of Dr. GUSTAV BUCKY's monograph *Grenz Ray Therapy*[2] is welcome, in that it gives a useful introduction to a recent development in radiotherapy. As their name implies, the Grenz or "borderline" rays occupy a position in the range of radiations between the ultra-violet and *x* rays, their wave-length being in the region of 1–3 Angström units.

To the first half of the book, devoted to physical and physiological considerations, Dr. Otto Glasser contributes a clearly and concisely written chapter on physics and apparatus, but the other chapters, notably those on the history, evolution, and guiding principles of Grenz ray therapy, are padded and somewhat involved. Similar criticism may be applied to the chapters on biological and clinical aspects of the subject, for these, too, while containing much that is of interest, are prolix and reiterative.

The chapter on the results of Grenz ray therapy in skin conditions is interesting. Without pretending to be other than tentative, it gives a list of diseases to which the method has been applied, indicates the doses used, and reports the results, whether good or bad. This, the really important chapter, occupies but twenty of the 170 odd pages of the book. Much more detail would have been of value here. Notably good results are reported in dermatitis herpetiformis, eczema of various types, rodent ulcer, naevus flammeus, and pruritus ani and vulvae. It is difficult to reconcile the results in rodent ulcer with the extremely feeble power of penetration possessed by the rays. The "half value layer" of skin for the average Grenz ray is in the region of 0.5 mm.: only 10 per cent. of the incident dose reaches a depth of 3 mm. If these initial results are confirmed by later experience, they indicate a remarkable selective action of Grenz rays on this type of carcinoma. Again, the author reports "good clinical results in six cases of tinea capitis," without depilation. The details are scanty, and only one case was followed up. The results, however, would imply a direct fungicidal action of the rays, such as is not possessed by *x* rays or thallium acetate. It is a pity that this matter, too, has not been pursued further. In a brief chapter on the treatment of internal disorders successful results are claimed in such diverse conditions as peptic ulcer, polycythaemia rubra, hypothyroidism, virilism, neurasthenia, menopausal arthritis deformans, asthma, whooping-cough, enlarged thymus, angina pectoris, myocardial degeneration, and, finally, spastic constipation. An imposing array!

In spite of the above criticisms, some of which the author discounts beforehand in a modest preface, this book, coming as it does from a pioneer in Grenz ray therapy, will be of interest and value to all interested in this form of radiotherapy.

ANTHROPOMETRY OF SCHOOL CHILDREN.

WHILE this country is notably lacking in modern statistics on the weight, height, etc., of its school children, America continues to produce many interesting studies of the "nutritional states," and the latest contribution to this subject is Dr. RAYMOND FRANZEN's *Physical Measures of Growth and Nutrition*.[3] This volume is the second of the School Health Research Monographs, and the author is director of research of the American Child Health Association. The material from which the anthropometrical analysis is made consisted of 7,509 elementary school children in seventy cities scattered over thirty-eight states. Besides crude weight and height many other measurements were made, including shoulder breadth, chest breadth and depth, girth of the upper arm, calf, and special measurements of subcutaneous tissue made possible by "subcutaneous tissue calipers." Most of the methods here described are too complicated for ordinary use—for example, in school clinics—nor does there seem to be much to be gained by such a detailed study for ordinary purposes. The first chapter is mostly concerned with showing how hopeless are the ordinary estimates of doctors in dealing with the nutritional states of children, and, in contrast, the rest of the book fairly bristles with mathematics to show how accurate such estimates can be made by measurement. The immense labour which has gone to the making of this book is of course commendable, and possibly some practical application of the results obtained will be found. For the moment the presentation of all these facts and figures is overwhelming, and the phraseology is throughout extremely difficult to follow and very "American" in style.

ANNALS OF MEDICAL HISTORY.

THE March number of the *Annals of Medical History*[4] contains seven articles dealing with very different subjects and periods, ranging from Roman architectural hygiene to the medical wisdom of Nathaniel Hawthorne, who did not "want to be a doctor and live by men's diseases." In the intervening pages there is much to interest the reader; under the heading of "Sons of Apollo" Dr. C. Jeff Miller gossips pleasantly about medical men who have written poems and verses; Dr. Carroll Camden, jun., analyses Elizabethan astrological medicine, and in much the longest article in this instalment Mr. Sonoma Cooper gives a fully annotated account of the school of Montpellier in the fourteenth century. In the article on the Irish School of Medicine, accompanied by portraits of John Cheyne on the cover and William Stokes on the frontispiece, Dr. J. Duffy Hancock devotes most of his space to the contemporaries

[1] *The Chemical Aspects of Immunity.* By H. Gideon Wells, Ph.D., M.D. Second, revised and enlarged edition. American Chemical Society Monograph Series. New York: The Chemical Catalog Company, Inc. 1929. (Med. 8vo, pp. 285. 6 dollars.)

[2] *Grenz Ray Therapy.* By Gustav Bucky, M.D., New York. Translated by Walter James Highman, M.D., New York. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1929. (Demy 8vo, pp. xii + 170, 40 figures. 15s. net.)

[3] *Physical Measures of Growth and Nutrition.* By Raymond Franzen, Ph.D. Being No. II of the School Health Research Monographs. New York: American Child Health Association. 1929. (6½ × 9¼, pp. xii + 173; illustrated. Paper cover, 1 dollar; cloth, 1.25 dollars.)

[4] *Annals of Medical History.* New Series, vol. ii, No. 2, March, 1930. Edited by Francis R. Packard, M.D. New York: P. B. Hoeber Inc.; London: Baillière, Tindall and Cox. (8 × 11¼, pp. 135–243; illustrated. Subscription in Great Britain £2 5s. per volume of six numbers.)

of Sir Dominic Corrigan, and records that, when a candidate for membership of the Royal College of Surgeons of England, the only question Corrigan was asked was "Are you the author of the essay on the patency of the aortic valves?" Dr. Hancock's contribution forms an admirable sequel to Professor Riesman's article on "The Dublin medical school and its influence on medicine in America," which appeared in the *Annals* in 1922. Another favourite subject with medical historians on both sides of the Atlantic is John Coakley Lettsom, and rightly so, for he had many points of contact with the United States of America; he was the first to send Jenner's vaccine lymph across the ocean, to Benjamin Waterhouse of Cambridge, Massachusetts, and, as recently pointed out in the *Annals* by Sir StClair Thomson, he provided Dr. Benjamin Rush with the seeds of the mangel-wurzel. In this number his relations with Jonathan Carver, the explorer of the Middle West, are set out by Dr. Victor C. Jacobsen. Among the reviews, always a pleasant feature, is an appreciative notice by Professor Thomas McCrae of Dr. Winslow's life of Hermann M. Biggs.

NOTES ON BOOKS.

The Life of Hermann M. Biggs,[7] by Dr. C.-E. A. WINSLOW, contains a captivating account of one who for the first ten years of his professional life was a pathologist, teacher, and practitioner, and then became a health administrator, with teaching and the practice of medicine as subsidiary activities. Besides being one of the foremost New York consultants in internal medicine, Biggs made the following contributions to the public health programme during his service with the New York Health Department: (1) the establishment of the laboratory; (2) the introduction of diphtheria antitoxin for prophylactic as well as therapeutic purposes; (3) the administrative control of tuberculosis; (4) the development of a scheme for the protection of child health, which included the control of midwives, the reduction of infantile mortality, the supervision of day nurses, and medical inspection of school children; (5) the promotion of rural health services; and (6) the control of venereal disease by the provision of laboratory tests for gonorrhoea and syphilis. Dr. Winslow emphasizes the point that Hermann Biggs was the most internationally minded of American health administrators. He paid frequent visits to Europe, where he took part in medical congresses, including the annual meetings of the British Medical Association. In London his fame has been perpetuated by the carving of his name on the façade of the London School of Hygiene and Tropical Medicine with those of twenty other sanitarians. Dr. Winslow's sympathetic biography is illustrated by numerous portraits of Biggs at different stages of his career and his contemporaries. A bibliography of Biggs's contributions to scientific and popular literature is appended.

We have received the entirely rewritten second edition of *Psychiatrie du Médecin Praticien*,[8] by Drs. DIDE and GUIRAUD. The book has been brought thoroughly up to date, and the authors have felt it desirable to accord more space than in the previous edition to the exposition and discussion of the most important recent contributions to psychiatry in France and other countries. The volume deals adequately with the clinical, pathological, therapeutic, and medico-legal aspects of psychiatry, and is sufficiently comprehensive to meet the needs of the student and medical practitioner. We have no doubt it will maintain the popularity which the first edition achieved.

The volume of clinical lectures by Dr. CONSTANTIN BACALOGLU,[9] professor of clinical medicine in the University of Jassy, contains 27 addresses, 16 of which are in Rumanian and 11 in French. The first lecture deals with the life of Laennec, and the second with medicine of the past compared with the present day, while the remainder are devoted to disorders of the circulatory system, especially angina pectoris, and blood, and hydatid disease. An introduction by Professor Emile Sergent of Paris is prefixed to the work.

Plant Biology,[10] by Dr. H. GODWIN, is based on lectures to first year medical students, and is intended to be a textbook primarily for their use. As principles have been selected that are likely to have a direct application to later and more specialized medical work, Dr. Godwin pays special attention to the physiology of the green plant, of bacteria and fungi, and to the chemistry of simple organic substances, as a preparation for animal physiology. Lucid and is given on such themes as crystalloids and olism of the higher plant, photosynthesis, yeasts, green algae, root, stem, and leaf. Another textbook, dealing with the economic aspects of the subject and addressed particularly to the honours student, is *Recent Advances in Plant Physiology*.[11] Mr. BARTON-WRIGHT urges the importance of research in plant physiology for its economic values, and surveys its progress from 1918 to 1929, discussing critically some of the more important papers that were published during that period in regard to the soil and water relations of the plant, transpiration, carbon assimilation, and nitrogen metabolism. The chapters of most general interest are those on respiration and the physiology of growth. Without deprecating the value of either of these books, it is possible to feel the need of a third book on the subject, with an approach neither entirely informative nor economic, but more comprehensive and synthetic in weaving plant physiology into the general scheme of biology.

A number of papers contributed by workers in the Connaught laboratories of the University of Toronto to British, Canadian, American, and French periodicals, from 1926 to 1928, are been collected and published as a third volume of studies.[12]

PREPARATIONS AND APPLIANCES.

RETRACTORS FOR BONE-PLATING.

MR. MAURICE G. PEARSON, M.B., F.R.C.S. (Durban), writes: The accompanying illustration shows a pair of retractors made for me by Messrs. Allen and Hanbury's Ltd. They have been in use for the last two years, and I have found them a great convenience, particularly in plating the shaft of the femur through the anterior incision described by Henry. Owing to their slightly clawed edges, which meet behind the linea aspera,

and to their weighted outer ends, they are self-retaining. When they are in place, with the towels tucked round outside of them, they leave nothing exposed except the necessary length of bone including the fracture. The risk of infection or laceration of soft structures is minimized, and the fixation of the plate is easier because the exposure is so complete. There is no difficulty in applying them; they "stay put" until removed, and their weighted outer extremities tend to lift forward the bone and restore its natural anterior bow.

AN AUTOMATIC ASPIRATING SYRINGE.

We have received from Bayer Products Ltd. (19, St. Dunstan's Hill, E.C.3) a sample of the "Behring-venule," which is an automatic syringe designed for the withdrawal of blood and other body fluids for pathological investigation. The venule consists of a stout glass tube from which the air has been removed. It is plugged by a special indiarubber cork in which is an ingenious valve connected with a hypodermic needle sealed to a glass tube. For use the tube covering the needle is filed and broken off, the needle is inserted into a vein, and by pressure the valve mechanism is opened so that the fluid enters the container; when sufficient fluid has been withdrawn the valve automatically closes. Special venules are provided containing sterile ox bile, sodium taurocholate, citrate, or fluoride, and other agents. In another type the fluid or pus collected is led on to an agar slope. These tubes can be obtained in packages conforming to the Postmaster-General's regulations for the transmission of pathological specimens, and accompanied by a wrapper for postal dispatch. They are also issued without this packing, in corrugated cardboard cartons containing twenty or one hundred.

RADIUM TREATMENT OF CANCER.

LECTURES BY PROFESSOR MURDOCH OF BRUSSELS.

PROFESSOR JOHN MURDOCH, head of the clinic of radiology in the Faculty of Medicine at Brussels University, and editor of the *Journal belge de radiologie*, delivered two lectures in London last week, one at a general meeting of the Fellows of the Royal Society of Medicine, with Lord Dawson in the chair, when the subject was "The radium treatment of cancer," and the other at the British Institute of Radiology, with Dr. N. S. Finzi presiding.

In his lecture before the Royal Society of Medicine Professor Murdoch said that all new methods of treatment passed through periods of exaggerated acclaim alternating with periods of equally exaggerated scepticism. Some radium institutes, however, had now been sufficiently long in existence to furnish statistics of a satisfactory kind; it was remarkable how similar were the results obtained in various clinics, although the methods used were entirely different. His lecture would be confined to those types of cancer in which the technique was more or less fixed—namely, epitheliomas of the skin, cancer of the tongue, and cancer of the uterine cervix. The various forms of treatment employed included external applications at certain distances from the skin, interstitial radiation by needles, intracavital applications, and distance treatment with the radium "bomb."

Cancer of the Skin.

In cancer of the skin the superiority of radium over *x*-ray therapy had been demonstrated. The reason for such superiority, whether due to the shorter wave-length of the gamma rays, or to the fact that radium was continuously applied for several days while *x* rays were applied only for short periods, was not very clear, nor was it known whether there was any essential difference between the biological effects of *x* rays and of radium when the time of application was identical. According to some research carried out at Brussels, it seemed probable that in order to produce the same amount of biological reaction, such as the erythema dose in the case of the skin, it was necessary to apply to the tissues a much larger amount of energy in the form of gamma rays than in the form of *x* rays, the proportion was about 4 to 1.

When it was necessary to limit radiation strictly to the part, on account of possible danger to adjacent structures, interstitial radiation by needling was employed. When the lesion was larger and situated in regions easily accessible, radium tubes, disposed in a carefully calculated manner, were mounted in a mould of Columbia wax, which was adapted to the shape of the part. Cures had been obtained in about 80 per cent. of cutaneous cancers of the face and lips, and in about 50 per cent. of the deeply infiltrated varieties, these last including a large number of inoperable cases. Cancer of the skin was never too large or too far advanced for radium therapy.

Cancer of the Tongue.

Cancer of the tongue was a condition most willingly handed over to the radium therapist by the surgeon, because surgical intervention caused an extensive mutilation, or operation might be contraindicated for other reasons. Even if operation was successful, local and glandular recurrences only too often took place. Whilst treatment by radium had not completely changed the aspect of this problem, yet even a slight improvement on the surgical results was a great boon to the patient. Cancer of the tongue was not a radiosensitive variety, and the radiosensitivity of the glandular metastases was even less than that of the primary lesion. After the first treatment acquired radio-resistance was very marked, and he preferred to resort to diathermy rather than to a second treatment with radium, although such second treatment might be useful. *X*-ray therapy of the tongue involved difficult technique; there was danger that the rays might injure the salivary glands, and also produce other damaging effects. Owing to the bad results obtained by deep *x*-ray therapy, preference was given to local radium treatment.

The methods of radium therapy of cancer of the tongue had been modified considerably. The introduction of radium into the tumour itself was the method now generally adopted, this interstitial radiation being applied by needles of platinum. Capillary glass tubes with emanation had been used, but a large proportion of the beta rays passed through, and the selective action of the gamma rays was entirely lost. Although the results obtained by Janeway and Quick were interesting, the speaker did not think the method had any future. His own method was to place in the growth platinum needles 1 cm. from each other containing radium element. This needling was quite easy when the lesion had developed at the margin or back of the tongue; it was more difficult, or even impossible, when the growth was situated at the base. The results of radium treatment of cancer of the tongue at the lecturer's clinic showed that in about 50 per cent. of all cases the local lesion could be cured.

Cancer of the Cervix Uteri.

Cancer of the uterine cervix was one of the first deep cancers to be successfully treated by radium, the good results being due primarily to the anatomy of the part, which was specially favourable to the disposition of the agent. *X*-ray methods had also reached in this condition a high degree of perfection, especially in Germany. Far from being opposed to each other, the two methods were probably destined more and more to be used together in the future. Definite statistics of the cures of cancer of the cervix uteri should include only such cases as had been under observation for five years following treatment. The method used in Brussels was the intracavital one. Radium tubes were introduced into the uterus and vagina, and to this was added transcutaneous irradiation by *x* rays. The disadvantages of the inter-titial method were the difficulty of disposing the needles correctly and of judging the size of the tumour.

Before the patients were admitted to treatment they had to undergo special examinations by the surgeon and the radiologist, and they were watched for twenty-four hours before the application of radium to ensure that there was no fever; only when the temperature was normal was treatment begun; dilatation of the cervix itself sometimes caused a rise of temperature. A simple apparatus had been devised, consisting of a small tube of aluminium, the walls of which were provided with grooves to ensure drainage; this enabled the radium tube to be inserted into the uterus with the minimum of dilatation. The intrauterine tube was left *in situ* for nine days, and the tubes in the vagina for five days. The absorption of quantities of energy equal to eight times the erythema dose to the skin—the maximum dose which could be applied to the skin with safety—produced no exaggerated reaction in this region. Trans-cutaneous irradiation with deep *x*-ray therapy was applied one month after radium treatment. An apparatus of 186 kilovolts constant tension was used, with a filter of 0.5 mm. copper and 1 mm. aluminium, the rays being directed through four portals of entry. Distant radium therapy with a "bomb" of four grams of pure radium might appear to be the ideal method of treatment for cancer of the uterus, but all who had tried it had seemed to come back to the local application. Hysterectomy after radium therapy had not been followed by very good results, and his own clinic had given it up entirely.

Results in Uterine Cancer.

After quoting the report of the subcommission of experts of the Health Committee of the League of Nations on the radiotherapy of cancer, the results obtained by Heyman of Stockholm and Regaud of Paris, which showed that it was possible to cure 40 per cent. of operable cases, the lecturer furnished some provisional statistics for his Brussels centre, which, he said, however, could not be

compared with the others because the five-year period for cases treated on the established technique was not yet completed. The total cases treated in 1925 and 1926 showed three years' cure in 28.5 per cent., the cases treated in 1927 showed two years' cure in 40.4 per cent., and the cases treated in 1928 one year's cure in 45.9 per cent. In the cases of 1928 the one-year cure was obtained in 50 per cent. of those which were operable, in 47.6 per cent. of the borderline, and in 45.4 per cent. of the inoperable.

Taking the figures reported from various centres, the five years' cure after surgery was obtained in about 35 per cent. of cases, and after radium therapy, in the operable cases, in about 40 per cent. Therefore radium therapy of the cervix uteri appeared to have a slight advantage over surgery. But it must be remembered that the results with radium were likely to be improved by successive developments in the technique, whereas Wertheim's operation was stabilized. In a very large number of cases where cure was not permanent, radium therapy made life tolerable. It would be premature to decide at present whether in quite early cases there should be an operation or radium treatment.

Time did not permit the lecturer to discuss fully the value of radiation in other forms of cancer, but he mentioned that, so far, cancer of the digestive tract had not given results with radium comparable with cancer in the regions with which he had already dealt. The introduction of radium tubes into the lumen of the oesophagus had proved a failure; it was possible that here the radium bomb might be useful. Radium in cancer of the stomach and duodenum was not satisfactory, and in Brussels these conditions were operated on as early as possible. Radium in cancer of the rectum gave similarly disappointing results. An ingenious method by Neuman and Coryn of interstitial needling from outside was used only in inoperable cases, and sometimes resulted in making a case operable.

Clinic Organization in Belgium.

To obtain the best results from radium therapy in cancer certain conditions of research and treatment were indispensable. The technique of radium therapy was not quite so simple as it looked. The co-operation of a large number of workers was necessary, and no branch of medicine called for so much team work. Professor Murdoch outlined briefly the way in which the cancer campaign had been organized in his country. There were State-endowed centres of research in each of the four universities; the subsidy was calculated according to the number of patients treated. Social work—the following up of patients—over the whole country was undertaken by a special organization. The university assumed the responsibility for the medical and surgical organization. At Brussels the senior professor of surgery, who was also in charge of the general surgical clinic, delegated to his senior assistant the responsibility for the surgical and radio-surgical work in the radium clinic. One pathologist dealt with the histological side, and there was a professor of radiology assisted by two physicists and another full-time assistant who specialized in radio-biological research. The staff also included a physician. Consultations were arranged three times a week. The surgeon, the pathologist, and the radiologist saw the patients together, and decided on the best method of treatment. The speaker remarked that this organization might appear rather complicated, but it had given good results during the four and a half years of its existence. The surgeon and the radiologist had come to have a great respect for one another, and mutual and unceasing criticism prevented any one member of the staff from becoming biased in favour of his own specialty. The surgeon even showed signs of becoming an enthusiast for radiation; the physician was one of the most useful members of the team.

The Role of the General Practitioner.

Although treatment by radiation was being perfected, said Professor Murdoch in conclusion, it was reasonably certain that radium would never cure more than a percentage of the cases, and cure of cancer ought not to be spoken of until some method was discovered of dealing with metastases as effectively as with primary growth. He paid a tribute to the work of Blair Bell and his associates, and also to the researches of Todd of Bristol, in chemotherapy, but he thought that these methods could not take the place of treatment by radiation, although they might be useful adjuncts. It seemed to him that the effective co-operation of many specialists such as were available in the modern clinic was likely to lead to the best possible results. The principle of centralization, however, was far from being approved, at least in his country, by the whole of the medical profession, and this was much to be regretted, since the efforts of the centres would be in vain unless they could count upon the effective and sincere co-operation of the general medical practitioner. In order to make the work of the centres really efficient it was imperative that patients should be sent to them at the first stage of their illness. Organized cancer centres had had to go through the disappointing period when only apparently hopeless cases were committed to their care. Happily now an ever-growing number of cancer patients were being received who had a good chance of being cured, but it was very necessary from this point of view that the general practitioners should work in close co-operation with the staff of the centre. The general practitioner had the most delicate task of all—namely, early diagnosis; he must encourage his patients to be thoroughly examined at the first suspicious symptom. Although there could be a too considerable increase in the number of centres of treatment, there could never be too many cancer diagnosis clinics.

Sir Charles Gordon-Watson, who proposed a vote of thanks to the lecturer, said that those who worked with radium in this country owed to Belgium—to Brussels particularly—much of their inspiration. The measurement of dosage was the outstanding problem at the present time, and here all workers felt that they were very largely in the dark; the work of Professor Murdoch and his Belgian colleagues had had its greatest value in the development of exact and standardized methods.

Professor Murdoch, in response, said that it had been a great encouragement to find that in England men were working in the same directions as in Belgium. In Belgium they had followed with great interest and with not a little envy the admirable effort which was being made under the auspices of the British Empire Cancer Campaign. Although the means at their disposal in Belgium were limited in proportion to the size of the country, he thought the methods and results were very much the same. There as elsewhere it was necessary to combat the idea that radium was a panacea for cancer, and that it would be sufficient to acquire increasing amounts of radium to solve the problem. More radium was certainly wanted, but not all the money should be spent on its acquisition; the provision of research laboratories was equally necessary.

Measurement of Radium Dosage.

In his lecture at the British Institute of Radiology, to an audience which greatly overcrowded the hall, Professor Murdoch entered more particularly into the question of measurement. He discussed the various units of radium absorption which had been put forward from time to time, and gave the reasons why in Belgium the ingenious method brought out by Stahel in 1928 had been adopted. This was expressed in ergs per cubic centimetre for the amount of radium energy absorbed. He showed many slides illustrating the disposal of the radium tubes so as to secure homogeneous radiation, gave tables for the distribution of the energy, and explained his method of interstitial radiation by means of needles laid parallel, as nearly as possible, in the tissues. He also exhibited the wax mould in which the tubes were mounted and which was adapted to the convexities and concavities of the part to be treated. He pointed out the limitations of the "bomb" method as compared with the interstitial method for securing intense action on the growth.

A vote of thanks was proposed by Professor F. L. Hopwood, and seconded by Dr. N. S. Finzi.

British Medical Journal.

SATURDAY, MAY 17TH, 1930.

SIR ARTHUR KEITH ON SPECIALISM.

In the oration which we publish in another column Sir Arthur Keith offers a critical examination of the facts and tendencies of modern medicine. Having emphasized the present picture by contrasting it with the picture of fifty years ago, he ventures into the realm of speculation, and wonders, with native and scientific caution, what developments are to mark medicine in the future. Nor is this all. As an observer and recorder of facts Sir Arthur deservedly enjoys an established authority. Not less is his zeal in the art of interpretation. And when all things are duly considered it is hardly a matter for surprise that the author of a famous presidential address to the British Association should find in "evolution" a collective phrase for the medical happenings and movements with which he is immediately concerned. Brass plates multiply in Harley Street, young doctors incline more and more to a consultant status and practice, seven specialists grow where only one grew before, hospital staffs are enlarged and particularized, laboratories displace closets with a few test tubes in our medical schools, National Health Insurance Acts and Local Government Acts, Sir George Newman and Sir Walter Fletcher appear in due season, and each as a distinctive mark of the "progress" which is another name for "evolution."

To some ears "evolution" is indeed a blessed word, but it does not suffice for those who seek after causes, and naturally, therefore, Sir Arthur Keith turns to consider what agency or influence is responsible for the phenomena he notes and describes. This he finds largely outside the strict field of medicine. It is not the ambitions or aspirations of medical practitioners, but new knowledge and new discoveries in chemistry, physics, and biology that account for added decorative displays in solemn West End streets, and for growing complexities in our hospitals and medical schools and daily practice. And the driving force behind all these activities and movements is provided hardly at all by human choice or even by human will. It is a stern and continuing Fate which points the way and provides the imperative impulse; that is, to modify a well-known couplet, "We progress because we must and not because we will." In short, what the philosophers foresaw is now being illustrated in medicine: increase in knowledge means increase in specialization, and increase in specialization is progress, and progress is evolution, and evolution is an "inexorable law." Effectively there is no escape, and therefore the outlook, provided it is not carried so far as to approach the end of all things, is a cheerful one. A regretful sigh the orator will permit over the disappearance of the pleasing illusion known as individual liberty, and he declines to write "fatalism," at least in large letters, as the title of his philosophy. None the less, in the procession of events which have carried medicine to the present phase and will continue to carry it, he detects little more than the fateful turning of the inexorable evolutionary wheel.

With Sir Arthur Keith's chapter of facts, whether his philosophy is accepted or not, there can be no dispute. Nor can anyone question the proposition that no man can be master of all that is known in medicine or efficient in all forms of diagnostic and therapeutic technique. A reasonable ambition does not nowadays take all knowledge, or even all medicine, for its province. Yet in spite of inexorable fate, we are tempted to suggest that in life, and even in medicine, specialism may possibly err by excess. Is there not a story of an earnest entomologist who, shutting out all other interests, spent unnumbered years in the study of one particular species of beetle only to find his closing years embittered by the caustic contradictions of an equally devoted observer? And was it a wrong judgement which, in the election of a president, directed the choice of a famous philosophical society against a distinguished judge who was reported to know nothing but the law, and in favour of a learned colleague who, on repute, knew everything except the law? The general has its value as well as the particular, and man may not live on specialisms alone. However plausible the suggestion that he is not "the master of his fate," he will yet surely strive to be "the captain of his soul."

Specialism in medicine is a well-worn theme. Even those who lament it allow that at least in some degree it is unavoidable. But this is not to admit either that every practitioner ought to be a "specialist" or that every patient ought to be examined by "a team." To put the position at its lowest, someone must remain to point the way to the appropriate expert, for it seems to be granted that the wrong expert may well be worse than no expert at all. More seriously, is it not beyond dispute that in numberless daily instances what the patient needs for his personal welfare is the general competence and trained judgement of one who has learned by first-hand experience to cultivate a wide outlook on clinical situations and problems, and to know that not everything is said by physical and chemical testings, however elaborate these may be? That in particular directions and at particular times such an adviser may need expert technical assistance is quite true. But this is to reinforce his value, not to diminish it. The art of medicine is a real thing, and it means something more than figures on a dial. When the issue concerns the individual patient someone must be prepared to see the problem as a whole and to exercise authority and to accept responsibility. Even when, as sometimes happens, contributions have to be brought together from many sources, there is need for a comprehensive and consistent picture in which each item is allowed its due proportion and is placed in a correct perspective. Someone in the last resort is in command of the ship and has the duty to speak the authoritative word. The individual clinical problem calls for balance and judgement as well as for knowledge and technical skill.

Sir Arthur Keith finds further illustrations of "inexorable law" both in the teaching organizations of

the profession and in the relation of the profession to the body politic. The pressure of advancing knowledge requires laboratories instead of lecture rooms, and a division and subdivision of subjects each of which but a few years ago was deemed well within the compass of a single teacher. No one, we imagine, will quarrel with laboratory instruction or greatly regret that a certain type of lecture is suffering eclipse. The more, however, the individual field is extended the more necessary becomes the need for selection. The medical student has much to learn and only a short time in which to learn it; and the practitioner of medicine deals in very practical affairs. Our pastors and masters must realize this position; for if, as we are told, physiology in the medical curriculum can now only be covered by three teachers where formerly one sufficed, it is certain that some selection in relation to utilitarian values will have to be made so far at least as the medical student is concerned. It was a substantial grievance that led an undergraduate to write over the entrance to a famous physiological laboratory "Abandon medicine, all ye who enter here." Sir Arthur fears that the urge towards research is depreciating the status of the teacher with corresponding prejudice to the education of the student—a development which those who value the disciplinary and cultural influences of a medical training must certainly regret. What is true of the curriculum is true also of new developments having clinical aims and ambitions. Here clearly the maximum of service is with those that come into widespread use in the ranks of the profession. With some technical methods and tests a restricted field is unavoidable, but the larger the area of possible employment the more substantial the gain to the art of medicine and the greater the benefit to those who look for advice and relief. The ideal practitioner would be able to use for himself all the methods and to collect at first hand all the evidence. Admittedly this is not possible or likely to be possible. All the same, the most effective pioneer is he who can devise methods which render new knowledge applicable over a wide field.

In the concluding part of his oration Sir Arthur Keith recognizes the pressure of the inevitable in the growing contact of medicine with Government and municipal departments and with public policy and opinion. Those who think that the profession can take its proper share in these enterprises without organization and a deliberate voice may read his argument with advantage. On the whole, though not without regret, he finds us the mere slaves of circumstance. A struggle for a fancied freedom may indeed continue, but with no real prospect of success. Yet it is well to be assured that even an apostle and prophet of inexorable law is ready to encourage our dreams and to cheer us on our fateful and inevitable way.

SICKNESS BENEFIT CLAIMS.

THE provision made for sickness and disablement benefits under the National Insurance Acts on the present valuation basis is such as to reproduce in the case of men the expenditure which would have been incurred had the claims been in agreement with the Manchester Unity of Oddfellows' experience for the years 1894 to 1897, due allowance being made for the first three days. In the case of women the basis is the actual experience of certain selected societies in the year 1923, *plus* ten per cent. For the purpose of the Royal Commission on National Health Insurance an analysis was made of the sickness experience of a large number of insured persons during the years 1921, 1922, and 1923, these persons being so chosen as to give a fair representation of the whole insured population. The Government actuary has now made a new examination of the experience of the years 1924 to 1927 of a comparable group of insured persons, and has issued a report (summarized in last week's *Supplement*) on the sickness and disablement experience of a group of approved societies during the whole period of 1921-27. The results set out in the report are somewhat remarkable and disquieting, and it is stated that the experience of 1928 and 1929 does not show any real betterment of the situation.

Separate analyses have been made throughout of the respective experience of men, of unmarried women (including widows as well as spinsters), and of married women, and it is found that with respect to each of these classes claims both for sickness and for disablement benefit have been rising continuously during the seven years. In the first three years all classes were well within the provision made for them, but for the last two years in the case of men and the last four years in the case of women the expenditure has been substantially greater than the provision. Comparing 1927 with 1921 the growth is such that as regards sickness benefit the claims of men have risen by 41 per cent., those of unmarried women by 60 per cent., and those of married women by 106 per cent., and as regards disablement benefit the percentages are 85, 100, and 159 respectively. A further analysis shows that the average length of the period over which the claim lasts has not materially altered. The increase must therefore be due to the variation in the number of claimants, and it is found that in the seven years the proportion of members claiming each year has increased by about 60 per cent. among men, 75 per cent. among unmarried women, and 100 per cent. among married women; and that of every thousand married women no fewer than 430 drew either sickness benefit or disablement benefit, or both, in 1927. A further conclusion to be drawn from the analysis is that the increase of claims is most pronounced in short illnesses.

A remarkable and significant state of affairs is disclosed as the result of an inquiry into the extent to which insured persons "declared off" the funds of approved societies soon after benefit was reduced from the sickness rate to the disablement rate. Of all claimants who passed from the one rate to the other during 1927 and ceased to draw benefit before the end of that year, more than one in six went off the funds almost immediately the reduction in benefit took place. Within a month of the reduction 50 per cent., and within eight weeks 70 per cent., had found their working capacity restored. This high proportion of restored capacity after reduction in the amount of benefit is common to both sexes and to all ages, but the proportion is much higher at the younger ages than at the older, and is especially heavy, at any rate up to the age of 50 years, among married women. It is true that a large proportion of those who "declared off" while in receipt of disablement benefit had to reclaim that benefit within a year thereafter, but a considerable degree of suspicion may reasonably attach to those cases where it was found necessary to reclaim shortly after the lapse of a year had enabled the claim to be made once more at the higher sickness rate.

The important bearing of the facts disclosed in this report upon the future of national health insurance is evident. If the present rate of expenditure on sickness and disablement benefits continues, most approved societies must experience a steady decline in the surpluses available for additional benefits at subsequent valuations, and ultimately many such surpluses,

and consequently such benefits, will disappear. It is not so easy to draw the moral. In the first place, some further investigation in certain directions is necessary, and, we understand, is being undertaken. This would seem particularly desirable with reference to recent or short claims, and with regard to recurrent claims. In the next place, it would seem that the policy of most societies in using their disposable surplus wholly or mainly for increasing the amount of sick pay is a mistaken one, and that, as we have urged before, it would be much better to use it for the provision of treatment, nursing, or convalescent benefits. In the third place, it must be remembered that the insurance medical practitioner's duty is to give a certificate of incapacity only at the request of an insured person, and, of course, then only when he assures himself that actual incapacity exists. Any increase in the readiness of insured patients to ask for certificates must therefore be a predominant factor in the number of claims made. Circumstances which promote this readiness are: (1) an increased familiarity with the working of the national insurance system and the opportunities it affords; (2) any widespread system of social legislation (whatever be its justification on other grounds) which tends to lessen reliance upon individual effort, thrift, and self-help; (3) a state of economic and industrial depression, and consequently a large volume of unemployment. It can scarcely be questioned that all these factors are at work to-day. In this regard the position of a married woman is different from that of others. Usually the husband also is employed, and a portion only of the family income is suspended when the woman ceases to work. A large acquaintance with the work of insurance practice leads to the belief that the insured man would as a rule far rather be at work than in receipt of benefit; that this is true also, though perhaps to a less degree, of the bulk of insured unmarried women; but that in a large proportion of cases the married insured woman would prefer to be at home attending as best she can to domestic duties and in receipt of sickness benefit, rather than to be engaged in other employment. A special class of whom this is largely true is the young pregnant woman or woman with a young baby. In all these cases it is often extraordinarily difficult to resist the patient's claim that she is "incapable of work" even though some doubt may exist. It may, nevertheless, be true that some insurance practitioners fail to remember that the contract between the patient and her society is an insurance contract in which the premiums entitle her to certain defined and limited benefits only and do not justify any claim to things beyond these, however desirable such other things may be.

Two inferences appear to be clear: first, that there is very little actual malingering among insured persons; and, second, that there is no widespread deliberate laxity of certification among insurance practitioners. We understand that statistics are now available showing the results of the cases referred to regional medical officers in respect of each insurance practitioner in comparison with the results for the area as a whole, and it is possible that there may be some individual cases in which it can be shown that a practitioner has failed to exercise reasonable care in the issue of certificates. If so, it will only serve to emphasize the fact, now, happily, more fully recognized than it was at one time, that any wanton or culpable laxity in certification cannot be charged against insurance practitioners, and that certainly any such laxity must occupy a very small place as a causal factor in the increased claims to sickness and disablement benefits.

THE SHAFTESBURY LECTURE.

THE eighth Shaftesbury lecture, delivered to the Shaftesbury Society and Ragged School Union last week by Sir George Newman, has been published as a pamphlet, and deserves the careful attention of all who are interested in the social welfare of the country. The lecture was entitled "Lord Shaftesbury's Legacy to the Children of England," and is one of those comprehensive, eloquent, suggestive, and essentially wise surveys of certain aspects of history and spheres of social science which we have learnt to expect from the Chief Medical Officer to the Ministry of Health and the Board of Education. After an admirably condensed summary of the condition of England into which Lord Shaftesbury (then Lord Ashley) emerged in 1832, and of some of the causes which had led up to that condition, Sir George Newman enunciates the social principles on which the reformer's zeal and actions were founded, and shows how, since Lord Shaftesbury's death in 1885, "his life was his bequest and the nation has become its executor: his vision and dream has become actual and has entered into the law and custom of the English people." Lord Shaftesbury's chief concern was with the children, and he was wise enough to see that it was with them that the country's chief concern should lie; in no place and at no time has so much been done for the welfare of the young as in England to-day. Though much may remain to be done, yet this is true with regard to the child's health of body, its education, its welfare in industry, and its protection from that which is evil. Sir George Newman well points out that in all these respects it was voluntary effort, drawing its inspiration from the example of Lord Shaftesbury and others, which led the way to State or communal action. "It is sometimes complained," he says, "that this is the wrong way round, and that there ought to be no need for voluntary effort, as the State should do it all. But our English way has substantial advantages on its side. It springs from the will of the people and has their assent; it throws the onus of responsibility on the parent; and it allows full weight to be given to experiment by trial and to experience." It is to the great, and yet largely unrecognized, honour of the medical profession that in the earlier part of the eighteenth century, when complete inattention to child welfare actually threatened the life of the nation, it was they, and they alone, who roused public opinion and initiated inquiries into cause and prevention, and that, much more recently, it was they who first suggested and continued to urge that attention to the physical condition of the child at school was a prime necessity. It has become clear that the chief difficulty of relying to any very large extent on voluntary effort is its uncertain and unequal scope and operation; nevertheless, such effort retains its virtues and advantages, and it is to be hoped that it may long be used wherever it can be made applicable. In spite of all Lord Shaftesbury's advocacy and effort it remained largely true, throughout at least the greater part of his life, that the welfare of industry, and not the welfare of the worker, was the main object of the nation's concern. It is not far from the fact to say that it is only in the present century that it has become generally recognized that, as the Duke of York said not long ago, "the welfare of the worker leads to the welfare of the industry." It is possible that to-day the vast extent and rapid expansion of State social services may be tending to outstrip resources; and Sir George Newman's lecture concludes with some suggestive but unanswered questions as to the exact results of our methods of attention to the child's physical health, of education, of imposing safeguarding conditions of juvenile labour, of dealing with juvenile delinquents and offenders. In the end "the State cannot usurp the place and duty of the parent in the upbringing of his child: it

[1] London: Shaftesbury Society and Ragged School Union, John Kirk House, 32, John Street, W.C.1. 2d.

cannot engender that domestic discipline and diligence which can alone prepare the adolescent for a world where 'play-atmosphere' must be exchanged for 'work-atmosphere'; and it cannot furnish the child with the uplifting and protective moral consciousness of a happy home life. It is in the home that the first victory must be won."

CHRONIC DUODENAL ILEUS IN CHILDREN.

AMONG the factors underlying chronic duodenal ileus in adults is believed to be some congenital malformation; it might be expected, therefore, that the investigation of cases in childhood might throw some light on the etiology of this condition. A valuable contribution to this end has been made by Drs. Reginald Miller and Courtney Gage, who, in a paper published in the current number of the *Archives of Disease in Childhood*,[1] describe a series of nine children who exhibited enlargement of the stomach, with visible gastric peristalsis or other signs of obstruction high in the alimentary tract. In summarizing the scanty literature they point out that cases have hitherto been classified in three main groups: one in which the type of duodenal obstruction is severe enough to produce a megaduodenum forming a visible and palpable tumour, usually during infancy; a second, among older children, in which the condition corresponds to the adult type; and a third, in which are included cases associated with other conditions and maldevelopments—for example, disease of the mesentery, or malposition of the duodenum. In two of the cases in the series described by Drs. Miller and Gage duodenal obstruction was proved at operation to be due to arterio-mesenteric compression of the duodenum. The symptoms of chronic duodenal ileus start in early life, even from birth, and are for the most part mild. The duodenal obstruction leads to gastric stasis and secondary catarrh, so that loss of appetite is the most troublesome symptom at first, with the development of vomiting as the child gets on to solid food and is forced to eat against its will. The physical signs of obstruction are not obstrusive; chief of them are enlargement of the stomach lying across the upper abdomen, and visible peristalsis. *X*-ray examination confirms the presence of obstruction to the evacuation of the stomach, and excludes the stomach itself as the site of the obstruction. More definite radiological information as to the presence of obstruction in the duodenum is usually lacking. The cases as a whole show a tendency towards gradual recovery, and although at first the obstruction is persistent with intermittent exacerbations, later, as spontaneous improvement sets in, the obstruction becomes intermittent, and suitable dietetic treatment may lead to the cessation of symptoms. It is thought, partly on the evidence of operation in two cases, that these signs and symptoms are due to some congenital anatomical obstruction in the duodenum, but lest the diagnosis be disputed in the cases under review Dr. Miller and Dr. Gage have used the term gastromegaly as an alternative to duodenal ileus, so that the syndrome may be recognized and described by other observers under one of these headings. In very young infants diagnosis of this condition has to be made from chronic duodenal obstruction due to other causes, such as congenital atresia or stenosis of the duodenum, or cicatrization of a peptic ulcer in the newborn, a very rare condition, an example of which is reported by Dr. Miller in the same issue of the *Archives* (p. 133). In children more than a few weeks old the differentiation of gastromegaly from duodenal obstruction produced by a peritoneal band gives rise to some difficulty. Clinically, cases of the latter type seem to fall into two groups: one of cases presenting the symptoms of megaduodenum; the second, of cases with dyspeptic symptoms, usually painful and interrupted by attacks of vomiting, in which the presence of an obstructive factor may be far less easy to recognize. With regard to prognosis it appears that the power of the stomach to develop hypertrophy and overcome the obstruction is almost the deciding factor. There seems to be a tendency for gradual improvement to set in spontaneously some time after the age of 5 years, though it may be many years before the vomiting attacks cease altogether. Under treatment Drs. Miller and Gage consider first of all the medical measures. The chief indication is to give a diet which is small in volume, highly nutritious, not too rich in fat, and calculated to pass out of the stomach as quickly as possible. To prevent fermentation of the stagnant gastric contents an alkaline antiseptic such as glycothymoline is advised. Castor oil is recommended as the best aperient, and gastric lavage and massage may be required. Surgical treatment, such as gastro-enterostomy, is to be considered as a last resource, and should only be performed when gastric hypertrophy has occurred.

THE CASSEL HOSPITAL.

THE annual report for 1929 of the Cassel Hospital for Functional Nervous Disorders by the director, Dr. T. A. Ross, deals only with patients treated during the previous year, as it is now the custom of the hospital to give only every third year a full report on all patients treated since it was opened. The interest of the triennial reports with their up-to-date after-histories on practically every patient is therefore lacking, but the present report raises some very interesting questions in its comparatively brief compass. During 1928 179 patients were discharged, of whom 145 were new. Of these, 94 were classed as psychoneurotics, and 81 of them improved or became well during their stay in the hospital. Six relapsed and some have not been heard from, but 71 out of the 94 have remained well or maintained their improvement for at least a year after discharge. The percentage of recoveries in this group remains remarkably constant from year to year. Some of the cases referred to are of exceptional interest. Two patients with an obsessive-compulsive psychoneurosis improved considerably with treatment, and one of them recovered completely after discharge. Recovery in long-standing instances of this condition is rare, and definite and lasting improvement after any form of therapy is also uncommon. It is interesting to note that the obsessive fears of one of these patients were found to be of things of which he had felt his father would disapprove, and that he recovered completely soon after his father's death. As happens too often, the credit for the process of recovery which was initiated by psychotherapy was given by the patient's relations to another form of treatment altogether, in this case osteopathy. Dr. Ross thinks that the role of the latter was to find a peg upon which the patient could hang the reason for his recovery, comfortably for himself, since it saved a direct admission of the real origin of his fears. The apparently direct relationship between the father's death and the cessation of symptoms is uncommon in obsessive-compulsive psychoneuroses, and is remarkable. Compensation neuroses are everywhere regarded as an insoluble therapeutic problem. Dr. Ross describes one case and alludes to several others under his care, which have recovered in response to psychotherapy. The usual advice is to hasten the conclusion of whatever litigation is impending, and, if compensation is obtained, that it should be a permanent settlement, not open to revision. After that, one hopes that recovery will spontaneously occur, since there is presumably no more to be gained. But this line of action is slow and unsatisfactory, and not seldom fails, at least for a long time, to produce any effect, since other factors may enter and prolong the symptoms. Sometimes a lump sum looks so much like a fortune that the bene-

ficiary remains luxuriously idle. The slow "spontaneous" type of recovery is so much the rule that it is very rare to find a case in which recovery could be reasonably attributed to psychotherapy. The Cassel Hospital cases should therefore be of considerable medico-legal importance when published in extenso. The origin and treatment of spasmodic torticollis is a vexed question. The present report mentions one case in which recovery followed psychotherapy. We know of a patient of this type who recovered in response to suggestion, only to relapse, and another with typical symptoms of short duration, who recovered for no apparent reason. With other types of spasmodic neck movements, the essential basis is often clearly compulsive or hysterical, but the origin of typical spasmodic torticollis remains obscure in most instances. Enough has been said to show that the report alludes to much that is of interest to practitioners of other branches of medicine besides psychotherapy.

WELFARE OF THE BLIND.

THE most noteworthy feature of the report of the Advisory Committee on the Welfare of the Blind[1] for the past year is the return of the number of the blind upon the register. The total of the registered blind population in England and Wales is now 52,727, an increase of 12.6 per cent. as compared with 1927. The ratio of the blind to the general population shows a steady upward movement. In 1919 it was 1 to 1,451, last year it had reached the high ratio of 1 to 749. The report, in commenting upon these figures, shows that as regards blind children under 5 years old there has been no increase. In respect of the age period below 21 there has been a decrease of 163 between 1927 and 1929, and a decrease of 177 in the preceding two years. The increase is most heavy after the age of 50, and these older blind persons account for 5,263 of the total increase of 5,905. It is reassuring to learn that there has been a decline in blindness among children. The committee hopes that further inquiry will be made as to the causes of blindness in infants, for it is still infants under the age of 1 that show the greatest incidence of blindness. Some concern is also felt at the proportion of the general population whose vision is so bad as to make them "too blind to perform work for which eyesight is essential," and at the large number of persons who become blind soon after reaching middle age. Many of these cases are known to be due to accidents and industrial operations; but there would appear to be an appreciable residuum in whom the underlying causes of the loss of sight are not so clearly defined. Blindness is, unfortunately, too often the concomitant of old age, but it is not certain that this need so often be the case, and we agree with the suggestion that there may be a fruitful field for inquiry into the whole question of the care and preservation of the sight of the adult population. In view of the substantial benefits now available for the blind, there is an inducement for persons who have serious defects of vision, but who are not strictly blind within the meaning of the statutory definition, to apply for inclusion in the register of the blind. In this connexion it is urged that medical evidence of blindness, based upon the considerations set out in the Ministry's circulars, should be obtained in every case before a person is accepted as eligible for registration. Investigation into the occupations of the blind reveals a steady increase in the number of those engaged in useful work, but this advance is set off by the huge increase in the number of the unemployable blind. In 1923 and 1929 the employed blind numbered 8,235 and 9,548. The corresponding figures for the unemployable were 20,759 and 37,563, and it should be noted that this increase of the unemployable is mainly after the age of 50. It is possible for many blind persons aged 50 (or even more in some instances) to be trained for successful employment; nevertheless, experience has shown that for reasons of health and aptitude it is an economic proposition for most. For this reason the committee is of opinion that the reduction of the age limit of 50 years for a blind pension under Section 1 of the Blind Persons Act, of 1920 to 40 years would be fully justified. Note is made of the valuable survey of the blind in this and other countries carried out under the auspices of the Health Section of the League of Nations; it was reviewed in the *Journal* of October 12th, 1929 (p. 685). This survey revealed that the services for the blind in this country are, on the whole, in advance of those abroad. There does not appear to be anything in other countries quite comparable to the home teaching and visiting service which has grown up here during the past ten years and has been of such high value in the amelioration of the hard lot of those blinded late in life.

THE BRITISH ASSOCIATION IN BRISTOL.

THE British Association for the Advancement of Science, which celebrates its centenary next year in London, will meet in Bristol from September 3rd to 10th, 1930, under the presidency of Professor F. O. Bower. The annual meeting in 1932 will be held at York, and that in 1933 at Leicester. The discussions this year at Bristol are being arranged in thirteen sections, most of whose sessions will be held in the magnificent new University buildings. The list of sectional officers has now been published in the preliminary programme issued from Burlington House. In the Section of Physiology all four vice-presidents are members of the medical profession—Professor G. A. Buckmaster, Dr. Carey Coombs, Professor W. E. Dixon, and Professor J. A. Nixon. Professor Edward Fawcett and Dr. George Parker are vice-presidents of the Section of Anthropology, and Dr. R. G. Gordon is a vice-president of the Section of Psychology. At the inaugural general meeting on Wednesday, September 3rd, Professor Bower will give his presidential address to the Association on "Size and form in plants," and on September 9th Dr. R. E. Slade will give an evening discourse on "The nitrogen industry and our food supply." Professor H. S. Raper's presidential address to the Section of Physiology will deal with the synthetic activities of the cell, and Professor C. W. Valentine's, in the Section of Psychology, with the foundations of child psychology. The Sections of Engineering and Physiology will combine for a discussion on air pressure variations encountered in engineering works and their physiological effects; and the latter section will debate jointly with the Section of Psychology "In what sense can we speak of primary colours?" This will be the fourth occasion on which the British Association has met in Bristol, previous meetings having been held in 1836, 1875, and 1898.

THE KING has appointed Mr. T. P. Dunhill, C.M.G., assistant director of surgery at St. Bartholomew's Hospital, to be one of His Majesty's Honorary Surgeons in succession to Sir Alfred D. Fripp (deceased). Mr. A. J. Walton, surgeon to the London Hospital, is appointed Surgeon to His Majesty's Household in the room of Mr. T. P. Dunhill.

THE British Empire Red Cross Conference, arranged by the British Red Cross Society, will be held on Monday, Tuesday, and Friday, May 19th, 20th, and 23rd. The proceedings will open on May 19th with an address of welcome by H.R.H. The Duke of York.

DIABETES AS A PHYSIOLOGICAL PROBLEM.

SECOND OLIVER-SHARPEY LECTURE BY PROFESSOR J. J. R. MACLEOD.

THE second and final Oliver-Sharpey Lecture by Professor J. J. R. MACLEOD of Aberdeen, on "Diabetes as a physiological problem," was delivered at the Royal College of Physicians on May 1st.

The lecturer reminded his hearers that in his first lecture two days previously (*British Medical Journal*, May 10th, p. 868) he had dealt with some of the laboratory observations which had recently been made on depancreatized animals, paying attention particularly to the difference in the course of the diabetes observed in fattened and in lean animals. Diabetes was found to be very much more acute in the former type of animal, and this indicated, or at least suggested, that some of the sugar must be derived from fat. At the end of the lecture he had alluded to certain other experiments which furnished more direct proof that this was the case. He did not intend to go further into that subject, as it had been sufficiently canvassed recently in another connexion, but would turn his attention to a part of the subject which he thought would be of increasing interest in the next few years—namely, the mechanism of the control of insulin secretion.

Control of the Secretion of Insulin.

It had become evident that deviations from the normal in respect to the control of the secretion of insulin might be responsible not only for symptoms of diabetes, but also for other conditions related to metabolic disturbances, particularly in connexion with excessive corpulence, excessive leanness, and several other disorders of similar type. The subject was a difficult one to deal with, because the information was so fragmentary in nature, but he had to make the most of it. The possibilities were, of course, that the secretion of insulin in the intact animal was regulated through the nervous system or through hormones. In the case of glands having an external secretion, like the salivary glands, it was very easy to demonstrate by direct methods control over the secretion. It was known, in a general way, that certain glands—more particularly those which had to act, as it were, at short notice, like the salivary glands, already mentioned, the lacrymal glands, and the sweat glands—were under nerve control, while others, which could act more leisurely, were subject rather to control by chemical influences.

The question was in what way any manner of control over the secretion of insulin could be demonstrated. It could not be expected that the difficulty of measuring the secretion was to be overcome by chemical analysis of the blood for insulin. The methods of preparing this substance, although admirable for its isolation in a purified state, were not sufficiently quantitative to be useful for detecting changes in its concentration in the blood. The production must therefore be measured by indirect methods, and obviously the most simple of these was to observe the behaviour of the blood sugar. A biological test for insulin was that it lowered the blood sugar, and therefore if it should be found, on stimulating a nerve, for example, that the blood sugar fell, it could be at least inferred that there was an increased secretion of insulin. That method had been used quite considerably, and he projected slides which indicated the results obtained by its use.

There were other methods, however, whereby variation in the secretion of insulin could be observed. They were, frankly, more or less indirect, but, taken together, he thought they were valuable methods. It was necessary to think of their use, not only in the laboratory animals, but also, of course, in man. The lecturer proceeded to describe the methods which were, in his opinion, the most useful. In the first place, it was interesting to observe the effect of the administration of sugar, given by the mouth or intravenously. This brought about an immediate rise in the blood sugar level, and produced the so-called assimilation limit curve, which, within certain limits, always followed a particular pattern. Sometimes, however, it was observed that the curve did not respond in a normal fashion irrespective of the diabetes. For example, it was found, after sugar was given, that the curve was likely to be more marked, to rise higher, and to be maintained longer in animals which had previously been deprived of carbohydrate than in those which had received this foodstuff. That, of course, recalled the old observation on so-called "starvation diabetes." After starvation the blood sugar, upon an administration of glucose, rose much higher and remained longer at the higher level than would otherwise have been the case. This was interpreted as meaning that the secretion of insulin was dependent on the amount of pre-formed carbohydrate. The observation had been made repeatedly also in man. It was made first of all really satisfactorily by Bang, but had been repeated many times since, and various things followed from it. It was found that when sugar was injected in divided quantities intravenously in man the effect of the first injection was much more pronounced than that of the later injections, and when the solution of glucose was continuously infused into the veins the blood sugar curve at first rose, then maintained a certain level for an hour or so, and gradually came down. Constant infusion of the sugar kept up a stimulation of the islets, so that the insulin that was secreted became effective as a result in lowering the blood sugar.

The Effect of Insulin on Blood Sugar.

The above was one interesting method of testing the secretion of insulin—namely, that of observing the response to the injection of a measured quantity of sugar. Some very definite results had been obtained by that method. Another obvious method was to observe the effect of insulin itself on blood sugar. The effect of a given quantity of insulin injected into an animal under standard conditions would vary according to the amount of the insulin that was being produced by the animal itself. Taking again fasting as compared with fed animals, it was easy to see that insulin had a much greater effect on animals previously fed on carbohydrate than on those which had undergone carbohydrate deprivation. The lecturer showed curves and tables illustrating the results of experiments in his former Toronto laboratory, the curves representing the blood sugar level in response to injection of glucose in solution and of insulin in normally fed rabbits. This particular influence of insulin was also very striking in the case of man, and was a factor of importance to remember, especially when insulin was being given for the first time in a case of diabetes. When insulin was injected alone into the animal it did not produce so marked a fall in blood sugar as when it was injected along with sugar. The injection of insulin along with sugar produced at first a slight rise in the blood sugar curve, followed by a fall.

Again, the difference between the percentage of sugar in the arterial and in the venous blood could be observed. This was really a very easy test to carry out. It was not necessary actually to obtain arterial blood for the purpose, the blood from the capillaries could be taken to represent it. The method consisted of comparing the blood sugar in capillary blood with the blood sugar in venous blood. There was normally a distinct difference between the percentages of sugar in the two bloods, but when insulin was injected or when insulin was being produced in excess from the pancreas this difference became much more accentuated. Instead of being somewhere about 10 per cent. it might increase to 20 or 30 per cent. This method was probably of value because it was a little more precise than any other dependent on the examination of venous blood alone. It showed what was happening in the tissues apart from the liver.

Nerve Control of Secretion.

Such were the principal indirect methods which could be used for measuring the internal secretion of insulin, and the question now arose as to what had been found out as to control. There was some considerable evidence that nerve control of the secretion actually existed, and that it was an important method for the adjustment of insulin production and relationship to carbohydrate metabolism. That the islets were under nerve control was suggested many years ago by the work of the anatomists. Several histologists had observed that the islets were richly supplied with nerves.

With these anatomical facts in mind, some demonstrations of nerve control were attempted in the lecturer's laboratory several years ago, and he showed a tabulation of the results. A fairly constant curve represented the blood sugar in an animal kept under ether anaesthesia. Another represented the result of stimulation of the right vagus nerves at the oesophageal end of the stomach. The stimulation of this nerve for a short period produced a very definite fall in blood sugar, with immediate recovery after the stimulation was removed, suggesting that the stimulation produced an internal secretion of insulin. The results not being conclusive, the subject was further pursued, but during the vagus stimulation there was quite definitely a fall in the blood sugar level and recovery after the stimulation was removed, showing that, at least under experimental conditions, the vagus had such an effect.

In France, La Barre had achieved, by an entirely different method, results which were of extreme importance. He used the method of cross-circulation, which had been extensively adopted in France in studying these problems of physiology. He connected, for example, the pancreatic-duodenal vein of one animal with the jugular vein of another. The second animal, into which the transfusion took place, would therefore respond to insulin by showing a fall in blood sugar if insulin were present in the blood. The anastomosis was not very difficult. La Barre found, after anastomosing the vein from the head of the pancreas of a large dog with the jugular vein of a small one, that the result of transfusing blood from the normal animal into one that was diabetic consequent upon the removal of the pancreas produced a definite fall in blood sugar in the diabetic animal. The insulin in the blood of the normal animal was sufficient to have an influence on the one which had been depancreatized. When both animals were normal there was no effect on blood sugar. Presumably the insulin content of the blood in the case of the other two animals, one normal and the other diabetic, was not the same. If he stimulated the vagus nerve in the normal animal, the blood sugar came down in the diabetic animal, the stimulation evidently exciting the secretion of insulin.

So far these results merely corroborated those of other workers in demonstrating the effect of stimulation of the vagus on blood sugar, but further researches by others showed that such nerve control was stimulated by an increase in the blood sugar. Intravenous injection of glucose into the donor animal caused the blood sugar of the recipient to fall by one-third. When the vagus nerve was cut in the thorax of the donor injection of sugar into this animal did not lower the blood sugar in the recipient.

Mode of Action of Injected Sugar.

The question which next presented itself concerned the mode of action of the sugar on the vagus. Did it act on the nerve centre itself, or might it be acting peripherally, as, for example, on the terminations of the vagus in the gland cells? That was a difficult thing to test experimentally, but it was done by La Barre by using three animals, between two of which a double carotid-jugular anastomosis was established, and the pancreatic vein of one of them anastomosed with the jugular of a third animal. The result of the experiment appeared to show that the secretory activity of the islets was under the control of the vagus centre, and that this was stimulated by concentration of glucose in the blood. When it was stated that the secretion of insulin was under nerve control it did not mean that nerve control was the mechanism by which those fine adjustments of insulin which must occur from time to time were regulated. Nerve control might be only an emergency control and occur only under certain conditions, but that it occurred was quite demonstrable.

The lecturer then referred to further experiments made on this subject by Clark of Sheffield, in some work which had been published in the *Journal of Physiology*, and which showed that in rabbits, besides nerves which could excite the secretion of insulin, there were also vagus fibres which produced a tonic inhibition of the secretion. After cutting the right vagus in rabbits, the animals, for about two months following the operation, being apparently in a normal condition, responded to the injection of sugar or to the injection of measured quantities of insulin in such a way as to indicate that the inhibition had been removed from the islets. Clark's conclusion was that the vagus, in addition to containing stimulating fibres, contained also tonic inhibitory fibres, which must be assumed to be more or less active all the time. There were in Clark's researches certain things rather difficult to explain, but it was not at all unlikely that the same nerve contained both excitatory and inhibitory fibres. For example, in connexion with respiration, the respiratory centre was constantly under the influence of impulses which were inhibitory in nature, and yet it could be excited by impulses which were excitatory, but which acted only under occasional conditions.

Hormone Control.

The fact that nerve control came into play under certain experimental conditions did not mean necessarily that the variations occurring in the discharge of insulin into the blood in ordinary life were regulated in that way. Indeed, it seemed reasonable to suppose that the islets were under chemical rather than under nerve control. Certain questions in connexion with hormone control here arose. Changes in the concentration of sugar in the blood might act directly on the hormones, and it was possible that if the tension of glucose began to rise above a certain level some other ductless gland was stimulated to produce a hormone which thus acted on the islets so as to bring about the secretion of insulin.

Were there any effects suggesting that hormones other than insulin had an influence on the carbohydrate metabolism, and, if so, did they act directly on the various mechanisms concerned in the production of sugar, or indirectly by influencing secretion in the islets? He took by way of example the results of experiments on the thyroid gland. It had been known for some time that the sugar was altered significantly by thyroidectomy or by feeding with thyroid. The thyroid gland, quite conclusively, had some very real connexion with the condition of the islets of Langerhans. How the results were to be explained it was difficult to say, but the fact was demonstrable, and was one that must have a very direct clinical application. It had to be borne in mind that thyroxine also had a very profound effect on metabolism in general, and it was permissible to suppose that the influence it had on hypoglycaemia was dependent on the over-stimulation of the secretory powers of the tissues which it brought about.

The lecturer went on to refer to certain cases in which there had been a pronounced hyper-insulinaemia. He read a number of reported cases, which, he said, established the existence of a hitherto unknown disease. One case described from Toronto by Campbell and others was of a woman, aged 52, who had noticed a gradual development of vague mental symptoms accompanied by excessive sweating for a period of six years before admission to hospital. Hyperglycaemia was found on admission, but there was a very dramatic response of the blood sugar to carbohydrate administration. The authors called the case "dysinsulinism." On operation a pancreatic tumour was found which proved to be a slowly growing carcinoma. The patient during the four weeks which the record covered remained free from her previous symptoms. The lecturer described other cases. There had been further advance in the clinical study of conditions which were not diabetic in the ordinary sense, but which bordered on the diabetic. Some very interesting results had been obtained in Vienna in patients showing excessive corpulence or excessive leanness, in children with epilepsy, and in cases of progressive muscular dystrophy, in which there were perfectly definite disturbances in the amount of insulin which could be measured in the blood by the methods he had indicated. It opened up an interesting field well worth exploring.

Substitutes for Insulin.

In some concluding remarks about substitutes for insulin, Professor Macleod said that a number of these substitutes had from time to time been sent to his laboratory. He had used one test for them. Could they, or could they not, remove the symptoms of diabetes from a depancreatized animal? None of them could. It was said that synthalin did remove the symptoms of diabetes from such animals,

but in his view it only did so very slightly, and it was quite possible that the effects which it appeared to have were dependent on the undoubted damage which it did to the liver cells. The whole work on synthalin pointed quite clearly to the fact that it had no action at all comparable with that of insulin, and that it was a dangerous drug to use on account of the indisputable damage to the liver cells which it occasioned. It had interesting effects on the consumption of sugar in the muscles, but it also produced lactic acid in the organism. It was always possible that these substances might have a pseudo-diabetic effect. The same applied to myrtillin, a preparation made from plants of the myrtle family.

MEDICAL CONGRESSES, 1930.

THE following congresses and conferences on medical and allied subjects have been announced for 1930. Particulars are given below in the following order: Date, name of organizing body, place of meeting, name of person to whom inquiries should be addressed. More detailed information about these meetings is given from time to time, as it becomes available, in the news columns of the *British Medical Journal*.

May 17.—International Exhibition of Hygiene. Dresden.

May 19–21.—International Congress on Malaria. Algiers. General Secretary, Institut Pasteur, Algiers.

May 30.—Société d'Ophtalmologie. Paris. Dr. René Onfray, 6, Avenue de la Motte Picquet, Paris, VII.

June 4–9.—Royal Institute of Public Health. Portsmouth. Secretary of Institute, 37, Russell Square, W.C.1.

June 5–7.—German Society for Psychology and Psychopathology. Vienna.

June 11–14.—German Society for Tuberculosis. Norderney.

June 21–28.—Royal Sanitary Institute. Margate. Secretary of Institute, 90, Buckingham Palace Road, S.W.1.

June 28 to July 2.—Journées Médicales de Bruxelles. Brussels.

July 3–5.—National Association for the Prevention of Tuberculosis. London. Secretary of Association, Tavistock House (North), Tavistock Square, W.C.1.

July 10–12.—Oxford Ophthalmological Congress. Oxford. Mr. C. G. Russ Wood, 12, St. John's Hill, Shrewsbury.

July 20–25.—International Society of Microbiology. Paris. Dr. St. John Brooks, Lister Institute, Chelsea Gardens, S.W.1.

July 26.—International League for Combating Trachoma. Geneva.

July 26–27.—Belgian Congress of Neurology and Psychiatry. Liège. Dr. Leroy, 30, Rue Hemricourt, Liège.

August.—International Congress of Cytology. Amsterdam. Fran Professor Rh. Erdmann, Berlin-Wilmersdorf, Nassauischestrasse 17.

August 3–10.—International Society of Sexology. London. Professor F. A. E. Crew, The University, Edinburgh.

August 4–9.—International Veterinary Congress. London. Dr. F. Bullock, 10, Red Lion Square, W.C.1.

August 5–9.—International Congress of Dermatology and Syphilology. Copenhagen. Dr. S. Lumholt, 45, Raadhusplads, Copenhagen.

August 12–15.—International Union against Tuberculosis. Oslo. Secretary of Union, 2, Avenue Velasquez, Paris, VIII.

August 18–21.—International Congress of Paediatrics. Stockholm.

August 26–29.—British Medical Association Annual Meeting. Winnipeg. Financial Secretary of British Medical Association, Tavistock Square, London, W.C.1.

August to September.—International Congress of Neurologists. Bern.

August.—International Congress on Miners' Phthisis. Johannesburg. International Labour Office, Geneva.

August.—Congress of Northern Neurologists. Stockholm.

September 1–6.—International Birth Control Conference. Zürich. Mrs. Janet Chance, c.o. A. S. Cobden, Esq., 10, Adelphi Terrace, W.C.2.

September 4–8.—International Congress of Physiotherapy. Liège. Dr. Dubois-Trépagne, 25, Rue Louvreux, Liège.

September 7–10.—German Society for Natural Sciences and Medicine. Königsberg.

September 15–17.—German Orthopaedic Association. Heidelberg.

September 22–27.—International Congress of the History of Medicine. Rome. Dr. F. Rocchi, Corso Vittorio Emanuele 173, Rome.

October 2–4.—International Society of Orthopaedic Surgery. Paris.

October 6–8.—Society for the Study of Diseases of Digestion and Metabolism. Budapest.

October 9.—Association Professionnelle Internationale des Médecins. Geneva. Dr. F. Decourt, Mitry-Mory (Seine-et-Marne), France.

October 27.—American Public Health Association. Fort Worth, Texas. Dr. H. N. Calver, 370, Seventh Avenue, New York City.

1930.—International Cancer Conference. Madrid.

1930.—Congress of Equatorial Medicine. Guayaquil, Ecuador

England and Wales.

Dr. Brackenbury a Freeman of Hornsey.

ON May 10th a special meeting of the Hornsey Town Council was held for the purpose of presenting to Dr. H. B. Brackenbury, a former mayor of Hornsey, and now Chairman of Council of the British Medical Association, the freedom of the borough. Consequent upon retirement from practice and removal from the locality, Dr. Brackenbury recently resigned his membership of the Hornsey Town Council. The occasion of the resignation called forth many tributes from his colleagues, and it was resolved to express in a tangible form to Dr. Brackenbury the council's appreciation of his services. The meeting, over which the mayor (Councillor Summersby) presided, was largely attended by members of the council and burgesses. The resolution that Dr. Brackenbury be admitted an honorary freeman was proposed by the deputy mayor, Alderman Double, who said that Dr. Brackenbury's long service to Hornsey was the more notable because he had never been a man of leisure, but had had to carry the burdens of a busy practice. A man's worth might be estimated by his reputation in his own profession, and there Dr. Brackenbury was held in signal honour. The Bar suffered when he decided to enter medicine rather than law, for his deadly logic and precision of speech had been extraordinarily effective in the furtherance of the causes he had at heart. The speaker associated Mrs. Brackenbury in the compliments. The resolution was seconded by Alderman Jenkinson, who claimed for Hornsey a certain credit because it was in the affairs of that borough that Dr. Brackenbury first won his spurs as a public man and discovered his gift of utterance. After the resolution had been carried unanimously and with acclamation, the roll was signed by the new freeman, and the illuminated scroll, having been read by the town clerk, was placed in a silver casket and presented by the Mayor to Dr. Brackenbury. The scroll recalled Dr. Brackenbury's periods of service in various capacities, enumerated some special achievements, notably in educational directions, in which he had played a leading part, and went on:

"... the special knowledge and extraordinary ability which have been brought to bear by Dr. Brackenbury on his conduct of public business, combined with his personal qualities and an untiring zeal devoted especially to the causes of education and public health over so long a period of time, have earned for Dr. Brackenbury a position of great authority in the whole country, and for this borough a reputation for progress and sound administration of which the town council and the burgesses are justly proud."

Dr. Brackenbury, who was very warmly greeted, said that the occasion might be considered as being both personal and public. On the personal side he felt great pride and honour at the passing of this resolution. According to the Oxford Dictionary, a "freedom" was the citizenship of a town or city conferred *honoris causa* upon eminent persons or those who had special claims to distinction. He repudiated once for all any claim to eminence, but he supposed that every person had a certain distinction, and the council had been good enough to indicate the distinctions he was supposed to possess, on the one hand, in the length of service, and on the other, in some degree of commendable accomplishment. The length of service was a mere historical fact, and, given good will on the part of those concerned, it was largely accidental that men gave long service in public capacities. His own entrance on public life was more or less accidental. In 1898 he was invited to stand for the old Hornsey school board, and under the curious system of the cumulative vote then prevailing he was returned at the head of the poll. During his first year he was wise enough to sit and listen to what appeared to him the remarkable and unintelligible jargon that educationists spoke in those days, and to say nothing at all. In 1902 he entered the council by uncontested election, and during the sixteen years that he was a councillor his return for South Harringay was never challenged. During his entire membership of the council he had never expended a penny on elections. But in other ways undoubtedly certain sacrifices were demanded. Service on public bodies

entailed a good deal of domestic separation, and here he paid a charming tribute to his wife for her patient co-operation. Asking why men entered the service of local councils, Dr. Brackenbury said that in almost every case the reason was public spirit, a desire for the public good. He believed there were very few instances of men seeking election on public bodies for some pecuniary or other advantage. In such a borough as Hornsey those engaged in its affairs had an enormously important task in teaching the growing citizens the way of life. Not that a local authority should supply everything that everybody could need, but it should see that those who were unable to provide the means for pursuing a good life themselves were *not deprived of them. He was quite unable to* enter into any community of feeling with those people who thought that the only or the first thing for a town council to do was to keep down the rates. He agreed that there should be no waste or laxity in the administration of public funds, but he had no sympathy at all with the attitude of such people as a motive for service. In the spheres of education and public health, Dr. Brackenbury continued, he had certainly done his best to help towards the necessary teaching and provision, and when he looked at what had been accomplished in thirty years he had no regrets. He claimed that in Hornsey rather more was being done for education than in the area of other local authorities. With regard to public health, here there had been nothing less than a revolution during the last thirty years. At the beginning of the century it was considered to be the function of a public health authority merely to look after such things as sanitation, water supply, and control, as far as was then possible, of infectious diseases. A wider conception had now come in, involving the inspection and treatment of school children, infant welfare, maternity care, and a widening of many things which pertained to the office of medical officer of health. There has been brought about a peculiarly intimate and confidential relationship between the administrators of public health and the profession to which he had the honour to belong. The authorities were using the profession in various ways to such an extent that as a consequence, by reason of the Municipal Corporation Act and other Acts, members of the profession, because they were rendering these services, could not themselves be members of public bodies. He pleaded, in the public interest—not in the interest of the medical profession—that those methods and wholesome traditions which had grown up in connexion with medical practice in this country should be as far as possible respected and encouraged. They would never have taken root as they had done if they had not contained some essential good. He hoped that his old colleagues in Middlesex, in their various health and sanitary services, would utilize all the knowledge and experience which the medical profession could bring, and would regard, at least with tolerance, if not with sympathy, the established methods and traditions to which he had referred.

London Voluntary Hospitals Committee.

"The London Voluntary Hospitals Committee" is the title that has been taken by the committee elected by the hospitals in the County of London for the purpose of consultations with the London County Council under Section 13 of the Local Government Act, 1929. The Section provides that:

> "The council of every county and county borough shall, when making provision for hospital accommodation in discharge of the functions transferred to them under this Part of this Act, consult such committee or other body as they consider to represent both the governing bodies and the medical and surgical staffs of the voluntary hospitals providing services in or for the benefit of the county or county borough as to the accommodation to be provided and as to the purposes for which it is to be used."

There has not hitherto existed in London any suitable body for this purpose, and a scheme of representation was therefore drawn up and submitted to the hospitals for their comments and approval by a *joint committee consisting* of representatives of the Voluntary Hospitals (Local Government Bill) Committee of the King's Fund, the Conference of Teaching Hospitals, and the London Regional Committee of the British Hospitals Association. The scheme provides that every hospital in the area shall have the right to nominate at least two representatives, one representing the governing body and one the medical and surgical staff, upon an electoral body which is divided into six sections for the purpose of representing five areas (North-Western, Northern, North-Eastern, South-Eastern, and South-Western) and the special hospitals whose work cannot be localized in relation to any particular area. Each of these five area committees and the Non-localized Special Hospitals Committee in turn elects its own representatives upon the central committee, the method of representation being such as to ensure that teaching, non-teaching, and special hospitals are each given proportionate representation. The meetings of the various electoral bodies were *convened in the latter part of March* by members of the joint committee, to which reference has been made above, and the central committee was able to hold its first two meetings during April. Lord Riddell is the chairman of the committee, and Dr. Geoffrey Evans the honorary secretary; the address of the committee is 23, Park Square East, N.W.1. The following are the members of the committee:

Mr. A. Lawrence Abel, F.R.C.S.	Mr. M. S. Mayou, F.R.C.S.
Mr. F. S. A. Baker.	Mr. E. Vernor Miles.
Lady Barrett, M.D.	Mr. Arthur Morley.
Mr. O. N. Chadwyck-Healey.	Mrs. E. W. Morris.
Mr. Thomas Clapham.	Mr. Gilbert G. Panter.
Lieut.-Colonel *Clement* Colbeld.	Mr. D. D. Pinnock, F.R.C.S.
Dr. Edmund H. Colbeck.	Dr. Arthur Porter.
The Right Hon. C. G. Craig.	Dr. Harold Pritchard.
Mr. R. Davies-Colley, F.R.C.S.	Lord Riddell.
Prof. L. S. Dudgeon, F.R.C.P.	Mr. D. W. Roy, F.R.C.S.
Dr. Geoffrey Evans.	Dr. T. H. G. Shore.
Mr. Arthur G. Ferard.	Dr. E. Bellingham Smith.
Mr. Charles Gibbs, F.R.C.S.	Mr. H. S. Souttar, F.R.C.S.
Sir Henry Gooch.	Mr. Widdrington Stafford.
Mr. E. L. Pearce Gould, F.R.C.S.	Mr. T. G. Stevens, F.R.C.S.
Dr. A. M. H. Gray.	Mr. Austin Taylor.
Captain A. M. Hughes.	Sir William H. Wells.
Sir Henry Jackson.	Mr. J. P. Wetenhall.
Dr. J. M. H. MacLeod.	Mr. Francis P. Whitbread.
Sir George Makins, F.R.C.S.	Dr. C. M. Wilson.

Medical Society of London.

Sir Arthur Keith's oration, printed at page 893, was preceded by a general meeting of the Medical Society of London on May 12th, at which Dr. R. A. Young was elected president for the next session, in succession to Mr. *Donald Armour*. Two interesting presentations were made to the society during the evening. Dr. Voelcker, the honorary librarian, announced that Dr. James Stowers, the oldest Fellow, had presented a portrait of Robert Willan (1757–1812), who might be called the first of British dermatologists, together with some manuscript letters and some pamphlets on skin diseases. The other presentation was made by Dr. Herbert Spencer, and consisted of fifty-three autograph letters by John Coakley Lettsom (founder of the society), together with a fair typescript of the same. Dr. Spencer said that the letters, which he had acquired from a bookseller, were dated from 1799 to Lettsom's death in 1815, and thus formed a supplement to the 293 published letters (of which only eighty were written by Lettsom) in his *Life and Writings*. The letters were addressed to John Nichols, the celebrated antiquary, who was also publisher of the *Gentleman's Magazine*, and to his son John Bowyer Nichols. The subject-matter was chiefly with regard to publications appearing in the magazine; in one letter Lettsom was pleased to observe that Mr. Nichols had mentioned the Medical Society fully and politely in his last number. The letters also dealt with the affairs of the Royal Humane Society, and touched on vaccination, bills of mortality, and other topics. The handwriting, Dr. Spencer said, was accounted for by the fact that Lettsom, a busy man, customarily wrote in his carriage. The letters gave a vivid glimpse of his activities. One of them offered an appointment at twelve midnight, but said that if that was unsuitable Lettsom would see his correspondent at seven in the morning. In one letter, writing about tobacco, he gave the authority of John Hunter and Benjamin Brodie as confirming his own experience with regard to the deleterious effects of that "vegetable." Although Lettsom made from £5,000 to £12,000 a year in practice, his many charitable gifts landed him in financial difficulties; in 1803 he proposed to sell his natural history collection, and in 1814 it appeared from the letters that he borrowed £100 from

Nichols. Some of the letters were letters of condolence, including one to his friend of forty years' standing, Dr. Combe (whose mother-in-law married Lettsom's son Pickering), on the loss of his son, and a few weeks later he records the death of his own son Pickering five weeks after his marriage. "My path," he writes, "seems to be over the ashes of my children."

Central Midwives Board.

At the meeting of the Central Midwives Board for England and Wales on May 1st a letter was read from the Maternal Mortality Committee, referring to the correspondence which has taken place between the Board and the Pharmaceutical Society with regard to the fixing of a standard of lysol suitable for use by midwives, and stating that a special investigation into the relative effectiveness of the various methods of hand disinfection was being undertaken under the auspices of the Medical Research Council and of the Maternal Mortality Committee. The Maternal Mortality Committee suggested that it was desirable to await the results of such investigation before laying down a specification as to the constitution of a solution of lysol suitable for use by midwives. The Board resolved to agree to this suggestion. A letter was read from the medical officer of health for the County of London stating that he proposed to recommend to his Public Health Committee that lectures on the rules and the relationship of midwives to the various health authorities should be delivered at the County Hall to the pupil midwives in training at the Council's various hospitals by the principal medical officer of the branch of the department dealing with the supervision of midwives, or by some other medical officer engaged in that work, and asking if the Board approved his proposal. The Board welcomed the proposal.

Scotland.

Health of Scotland.

As announced in this column last week, the first annual report of the Department of Health for Scotland, covering the year 1929, has now been issued.[1] Much preliminary work has been done by the Department in preparing for the transfer on May 16th, 1930, to county councils and town councils of large burghs of the functions previously discharged by local authorities of smaller districts. It is pointed out that there is a widespread intention to transfer hospital treatment of the sick from the Poor Law, but that it will take some time to carry this into practice; for while the Poor Law stigma may be removed by treating patients under public health powers instead of under those of the Poor Law, there still remains the discrimination against the sick poor in consequence of their treatment in institutions having a lower standard of equipment than the public health hospitals. The two main difficulties in the way of reorganization are the general shortage of hospital beds in Scotland and the fact that existing Poor Law buildings are, as a rule, not suitable for the work of a modern hospital.

Housing and Town Planning.

In the ten years that have elapsed since the first Act authorizing State assistance for housing schemes in 1919, over 106,000 houses have been built in Scotland, accommodating nearly half a million persons, or one-ninth of the working-class population of Scotland. There is still, however, a shortage of at least 100,000 houses, which are estimated to take another decade to provide at the present rate of building. The output of houses has been steadily diminishing during the last two or three years, and as this may have been caused by the reduction of the rate of the subsidy in 1928, attention is drawn to the means by which greater allowances may be obtained by local authorities. The report urges the necessity for proceeding with the improvement of the housing conditions of farm servants, and outlines the directions in which this might take place. It mentions that in one large burgh 346 houses have been erected in which lighting, cooking, and the washing of clothes are done by electricity at an extra capital cost of only £7 per house, and that the corporation of Glasgow is making experiments with this type of house in four large rehousing schemes. Some idea of the future of regional planning in Scotland is obtained by the statement that over 3,000 square miles are included in four regional schemes which are in course of preparation for an area extending across the Scottish Midlands and embracing the industrial belt.

Slum Clearance.

The shortage of houses in Scotland during the last fifteen years has intensified the problem of the slum, so that many houses ready for demolition must continue to be occupied until alternative accommodation has been provided. Local authorities after the passing of the Housing (Scotland) Act, 1919, advised the closing down of over 34,000 houses. In ten years 11,000 houses have been provided to replace those closed under improvement schemes, but 23,000 houses are still required in the five large cities of Scotland alone for this purpose, according to the reports of medical officers of health. The census of 1921 revealed that the number of one-apartment houses in Scotland was 124,369, of two-apartment houses 424,238, while nearly one-fifth of the total population was living more than three to a room, and about one-half more than two to a room. The hope is expressed that the census of 1931 will indicate some improvement on these figures owing to the activities of local authorities, but it is pointed out that the problem of overcrowding is closely connected with the problem of slum clearance. The reports of the medical officers of health for Glasgow and for Edinburgh show that high death rates and high infant mortality rates are also associated with overcrowded areas. Medical officers of health and school medical officers reported that during 1928 and 1929 the condition of children affected by slum clearance schemes had materially improved.

Food Supply.

The report remarks that the consumption of milk in Scotland is still too low, and that an educational effort is required to bring home to consumers the high value of milk as a food for children. Experience of the working of the Milk and Dairies (Scotland) Act, 1914, has shown that if veterinary inspection is to have a reasonable measure of success in preventing the retention of tuberculous and other diseased animals, it must take place more than once a year. Four inspections a year are common in burghs, and in some instances there are monthly inspections, but in most inland districts, which include some of the leading dairying counties, the local authorities have not yet seen their way to provide for more than the statutory minimum of inspection. Dairy by-laws of local authorities under this Act are in operation, however, in practically all landward areas, and help to prevent contamination of milk supplies by dirt and disease of dairy workers. Reports by some county sanitary inspectors have revealed a formidable list of defects at dairy premises, such as lack of adequate water supply and of facilities for washing and scalding milk vessels. About 108 tubercle-free herds of cattle are now supplying graded milk. The Department has issued a direction that on and after July 1st, 1930, the double intradermal test alone should be used in all tuberculin testing of cattle, and that this test should meet the desire of producers for a uniform test upon which reliance can be placed. Meat inspection has been greatly improved by the operation of the Public Health (Meat) Regulation (Scotland), 1924; the arrangements under this Act are stated to be working effectively. Regulations concerning preservatives in food are also working smoothly, and the trades concerned are apparently adjusting themselves to the new conditions. Of 264 samples of mince analysed for local authorities during 1929, 29.9 per cent. were found to have been adulterated by preservatives.

Mental Welfare in Scotland.

The Rt. Hon. William Adamson, M.P., Secretary of State for Scotland, delivered an address on May 4th in Glasgow at the annual meeting of the members of the Scottish Association on Mental Welfare, under the chairmanship of Sir Henry S. Keith. Mr. Adamson referred to the recent opening of two institutions for mental defectives in Scotland—namely, Lennox Castle, provided by the Glasgow

[1] Cmd. 3529. Edinburgh: H.M. Stationery Office. 3s. 6d. net.

authorities, and Gogarburn House, established by the Edinburgh Parish Council. He thought that many more of these institutions would probably be required. Apart from institutions altogether, there would always be many mentally defective persons who required the care and friendly help of that association, which had about nineteen local care committees operating in the areas of twelve different education authorities. Some of these had done pioneer work in setting up employment and occupation centres which encouraged out-of-work pupils to develop the knowledge they had obtained in special schools, and to earn a little towards their maintenance. These centres kept the mentally defective under supervision, and prevented deterioration of mind and body. The careful notes that were being made of individual development would undoubtedly be of value in research on mental deficiency problems. Great progress had been achieved since the association was founded seven or eight years ago. The present was an important period in the history of the association because many local authorities would shortly disappear. Mr. Adamson recommended all county and town councils in Scotland to support the association by appointing representative members and by subscribing liberally to its funds. Councils could secure much valuable help in their work from local care committees. Dr. D. K. Henderson of the Glasgow Royal Mental Hospital thought that a research centre should be established to set a standard for mental work throughout the community.

The Menace of Smoke to Health.

Dr. J. R. Currie, professor of public health at Glasgow University, who delivered an address on May 9th to the Scottish branch of the National Smoke Abatement Society, on smoke nuisance and radiation, said that in winter the smoke cloud over cities assumed the form of fog, because condensation readily occurred on the numberless particles of soot in the atmosphere when damp air was near the point of saturation. The total quantity of this material in Glasgow during 1929 was equivalent to a fall of soot of 278 tons per square mile. The thick pall created by such fogs shut out sunlight and reduced the temperature. Frost combined with fog raised the respiratory death rate; in Glasgow one November a five-day fog accompanied by frost increased the number of deaths from respiratory diseases from 75 to 138 in the week of fog and to 233 in the following week. In order to diminish this evil Dr. Currie suggested that gas fires or electric radiators were excellent for household heating and cooking, although the open fire might be most suitable on hygienic grounds in a room which was continuously occupied. Dr. A. S. M. Macgregor, medical officer of health for Glasgow, remarked that respiratory diseases now constituted the infectious diseases of their large cities. With the decrease in the effects of other diseases more and more attention was being paid to the incidence and control of respiratory disease, with which the question of smoke abatement was intimately associated. Experiments had revealed that the pollution of the air in Glasgow was caused largely by domestic fires; the elimination of domestic smoke was one of the problems of this campaign. A completely smokeless atmosphere might be anticipated as coal became too precious to be wasted. Professor R. W. Dron, of the department of mining engineering at Glasgow University, advocated the use of anthracite as a smokeless fuel, and said that the smokeless condition of such cities as Paris and Berlin could be explained mainly by the fact that these cities used Scottish anthracite. It was a curious fact that anthracite was sent overseas to make other cities smokeless, while Glasgow and Edinburgh remained in smoke and grime.

Edinburgh University Chancellor.

A meeting of the General Council of Edinburgh University, which comprises all the graduates on the roll of the university, was held on May 7th. The Principal, Sir Thomas Holland, presided, and three candidates, the Marquess of Linlithgow, Sir James M. Barrie, and Lord Macmillan, were nominated. A vote by a show of hands resulted in Sir James Barrie obtaining a majority of nineteen votes over Lord Linlithgow, whose supporters, according to the regulations governing the appointment, demanded a poll of all the members of the General Council resident in Great Britain. Voting papers have therefore been sent out to the 18,000 graduates of the university; these must be returned within twenty-one days from the date of nomination.

India.

Kashmir Mission Hospital.

THE importance of co-ordination in medical relief is emphasized in the annual report of the Kashmir Mission Hospital in Srinagar for 1929. Dr. E. F. Neve, medical superintendent of the hospital, comments on the necessity of co-operation between official and voluntary health organizations, and commends the marked sympathy and help which have been received from the medical department of the Kashmir Government and its director, Lieut.-Colonel Hugo, I.M.S. Dr. Neve mentions a liberal grant made towards the work of the hospital by the Maharajah of Kashmir, and adds that the improvement in the general medical service in Kashmir during the last twenty years has been particularly notable. He contributes to the report an account of the maternity and infant welfare work in that State. About one-third of the patients who attend the hospital are women and children, insufficient food being in many cases one of the chief causes of illness. Osteomalacia is common; Dr. Neve thinks that this disease is probably toxic and, like goitre, is due to some special form of infection related to insufficient exposure to sunshine consequent on the conditions of life. Hindu women form less than 10 per cent. of the population of Kashmir, but nearly 30 per cent. of the osteomalacia patients are of this nationality. Cholera has been practically absent since 1925, when there was a serious outbreak affecting about 22,000 cases, with a mortality of 50 per cent.; this disease reappeared, however, in October, 1929, when between 200 and 300 widely scattered cases appeared, and the danger of a grave recrudescence in this present year is obvious. A Government tuberculosis dispensary has been started in Srinagar, and it is hoped that a sanatorium will be established later at Tangmarg or elsewhere. Tuberculous joint disease seems to be becoming more common. The total number of surgical operations performed in the Mission Hospital during 1929 was 6,015, with a mortality of 19. This hospital—which is conducted by the Church Missionary Society—has won widespread popularity, and the present report illustrates well the variety of ways in which it is rendering most effective service to the community.

Progress of Antirabic Treatment.

An apparent decrease in the mortality from rabies in the Madras Presidency is indicated by the report of the Pasteur Institute at Coonoor for 1928–29. In 1928 the number of deaths from rabies registered in the towns was 71, and 493 were recorded in the rural areas, giving a total of 564, as compared with 636 in the previous year. Registration of statistics appears to be defective, however, in many towns and districts. On the other hand, the fall in the death rate may be partly explained by the fact that larger numbers are reported to be seeking treatment as a result of effective propaganda on the part of the public health authorities and the provision of more facilities for treatment. Four additional centres were opened during the year. A new concession has been granted by the Government to local bodies, exempting them from the payment of the cost of antirabic vaccine supplied by the institute to Government hospitals for the treatment of indigent patients from district and municipal areas. Issues of vaccines at local centres rose from 4,700 to 5,600, and 465 patients were treated at the institute, an increase of 71. Following the recommendation of the international rabies conference, held in Paris in 1927, statistics were not compiled until six months had elapsed from the date of the completion of treatment. Four patients, who had completed the full course at the institute, are reported to have died of hydrophobia, one less than fifteen days, and three more than fifteen days, after treatment. Semple's carbolized vaccine was used throughout the year; the vaccine is

allowed to mature for a fortnight in the refrigerator before it is used, and it is not considered efficient for more than three months after the date of its preparation. During the last two years patients attending the Kasauli Institute have been treated with etherized vaccines (Alivisatos's method) as well, and the dose and period of treatment have been varied according to the severity of the case. Comparison of the effects of the different methods in use was expected to be published at an early date. Major R. H. Malone, I.M.S., officiating director, Pasteur Institute of India, draws attention in his report to the difference of opinion that seems to exist in regard to the period that must elapse before treatment is considered unnecessary in suspected cases. The two months which has been suggested is too short, he thinks, because he has found that about 12 per cent. of the deaths from hydrophobia among patients who have been treated occur between three and six months after they have been bitten. At Kasauli, during 1928, treatment was regarded as unnecessary where a period of six months had elapsed. The death is recorded of a European whose hands were licked by a rabid animal, though he was subsequently treated with carbolized vaccine; the saliva alone came into contact with scratches on both hands, the patient not being bitten. A few complaints were received about the unfavourable effects of antirabic treatment on the general condition of health. It has been observed at Kasauli that patients who have previously had malaria tend to have a relapse during a course of antirabic treatment. Experience has also shown that headache and insomnia are comparatively common complaints, and that giddiness, fainting, and palpitation may be reasonably ascribed, partly at least, to this cause.

Correspondence.

ACUTE PERFORATION OF THE STOMACH AND DUODENUM.

SIR,—While appendicitis still holds first place as a cause of the "acute abdomen," pyloric perforation will probably soon occupy second place, if it does not already do so, and perhaps I may comment, therefore, on the pyloric aspect alone of some of the points raised by Mr. A. G. Bryce in his interesting article in the *Journal* of April 26th (p. 774) and in the letter of Mr. Struthers (May 3rd, p. 838).

I am glad to find that Mr. Bryce supports my contention that many of these ulcers should be described as pyloric. What is probably of greater importance than the relationship of the ulcer to the pyloric vein is its relationship to the sudden transition from the thick-walled, freely movable, and easily stitched stomach, with a thick succulent mucosa, to the thin-walled, fixed, and rather rigid duodenum, with a thin mucosa, which does not lend itself so readily to plastic requirements and stitching.

Mr. Struthers agrees with Mr. Bryce that the addition of a gastro-enterostomy to an operation for the closure of a perforation should be reserved for cases in which stenosis is present or is likely to result from healing. I also feel strongly that a gastro-enterostomy is an undesirable addition, particularly where the patient is already suffering from shock, and speed is desirable, but I would like to raise the question whether there is any need of this operation, or whether any advantage is to be gained by performing it in the great majority of cases, provided that the pyloric ulcer is appropriately treated. When Mr. Struthers states that the results obtained by Mr. Bryce are exceptionally good, and should be accepted with caution as a guide, I think it is worth while asking whether Mr. Struthers and Mr. Bryce have exactly the same treatment of the pyloric condition in view. Mr. Bryce says: "The method of treatment was to invaginate the perforation by two layers of suture. . . . At the pylorus and in the duodenum the *suture line was made to lie in the transverse axis of the bowel*" (italics mine). If I understand Mr. Bryce aright, therefore, his method of treatment approximates to mine, which has the double object of removing the ulcer and of widening the pylorus by means of a pyloroplasty, thereby rendering the occurrence of stenosis extremely unlikely. I think it is wise to excise the ulcer, since, whatever its pathology may be, its walls are not healthy, and frequently present a curious cartilage-like consistency and brittleness. This condition may invade a considerable portion of the pyloric wall, rendering any but through-and-through stitches liable to cut out.

The method of excising the ulcer and performing at the same time and by means of the same incision a pyloroplasty, so as to produce a wide pylorus, is one I adopted some twenty years ago; I became so convinced of its value both as regards the immediate results and, so far as I could judge, the later effects, that I have advocated it to my students for many years past, and gave a short description of it in my *Textbook of Surgery*, published in 1922. At first I made the ulcer the centre of a horizontal incision running parallel with the axis of the bowel, but I now prefer to place the ulcer near the duodenal extremity of this incision. The ulcer is excised and the pylorus opened. The finger is introduced through the opening, and both stomach and duodenum are explored to ensure the existence of a perfectly free passage; with the finger still in position, a couple of retracting stitches are introduced, one at the middle of each side of the horizontal incision. On an assistant making traction by these stitches the horizontal incision becomes first diamond-shaped, and finally reverses its axis, so that it is now vertical, or transverse to the axis of the bowel, while the pylorus becomes correspondingly short and wide. The wound is stitched in this position, transverse to the axis of the bowel. As it is difficult to close this wound with an ordinary continuous in-and-out and-across stitch, such as is used in a gastro-enterostomy, three or more interrupted sutures on the in-out-and-across principle are inserted; these are tightened; the edges of the wound are seen to be inverted, and then they are further tightened and tied. The wound may be reinforced by a continuous serous-to-serous suturing, if the condition of the tissues will permit, but it is seldom necessary, and omental tissue is fixed down over the line of incision, and a drain inserted. The operation occupies little more time than any other method of dealing with the ulcer, and, in my opinion, renders it quite unnecessary to consider the pros and cons of a gastro-enterostomy. Only very rarely, in my experience, is the pylorus so extensively diseased and deformed as to render this operation inadvisable, although it may be difficult.

Notwithstanding the excellent results obtained by this method I now consider it important, irrespective of the type of operative treatment adopted, to administer a *teameal before the patient leaves hospital, and, founded on* this, to give him advice as to diet, regulation of the bowels, and in particular, if there be hyperacidity, to insist on the regular use of an antacid. In this connexion I am pleased to see Sir James Barr recommending chalk as an antacid in his letter (May 3rd, p. 839). Long personal experience enables me to say that prepared chalk is the only antacid of the many I have tried that is really suitable for regular use. Its chief drawback is messiness, and this can be largely obviated by using tablets.

Mr. Bryce refers to a pre-perforation stage, with severe and uncontrollable epigastric pain, as described by Continental writers. I have seen a few cases of this type recently. On account of the character and severity of the pain they were sent to hospital as acute perforations, and were operated on under the belief that they had perforated some hours previously. In one, operated on by Miss Ellen B. Orr, one of my assistants, the ulcer had not given way, the serous coat remaining intact, although covered with inflammatory lymph. In another, on which I operated, the ulcer gave way just as my hand was introduced over it, the hand receiving a jet of stomach content. In yet another the ulcer had obviously just perforated although it was not actually seen giving way.—I am, etc.

Glasgow, May 3rd. J. MACEWEN.

SLEEP IN HOSPITALS.

SIR,—May I congratulate you on bringing the question of sleep in hospitals to the notice of your readers?

The difficulty of allowing the patients who are seriously ill to sleep whilst the more convalescent are being washed is of primary importance. I have asked some of my architect friends to design shutters which could be unrolled from the ceiling and thus enclose special patients in a sound-proof box; but so far no practical solution has been sent to us.

The point about hospital patients being accustomed to early rising is not so true at the present day as it used to be. Many big firms have given up work before breakfast because of the greater efficiency obtained by men starting work later.

There is one other point that you do not mention in your article—that is, the effect that this early waking and washing has on the training of nurses. They carry out into the world the idea that it is essential for patients in private to be washed before 7 a.m.—I am, etc.,

London, W.1, May 6th. MALCOLM DONALDSON.

PUERPERAL INFECTION.

SIR,—The article on puerperal sepsis by Dr. Farquhar Murray in the *Journal* of May 3rd (p. 814) is concerned with matters of such importance that it cannot be allowed to pass without comment. Dr. Murray has compared, during two successive years, the incidence of sepsis amongst parturient women before and after exclusion of all possible sources of infection. From May till December, 1929, all cases infected on admission to hospital or likely to become septic were nursed in special isolation wards. Any case of pyrexia which subsequently developed in the general maternity ward was also removed for isolation. The net result of these procedures has been the reduction of the sepsis rate in the maternity wards to the low figure of 1.6 per cent. Dr. Farquhar Murray attributes these favourable results to removal of infected contacts, and concludes that puerperal pyrexia in maternity hospitals is due to contagion.

The result of our personal investigations has been to convince us that the problem of puerperal pyrexia resolves itself into a consideration of two main groups of cases: (1) a contagious group due to *Streptococcus pyogenes*, including the severest forms of puerperal fever; and (2) a much larger group of milder cases, the result of autogenous infection by a variety of organisms normally present in the female passages, which assume minor pathogenicity in consequence of the injuries and exhaustion associated with prolonged labour and instrumental delivery. It is, we believe, a common experience that cases belonging to this milder group (to which undoubtedly the *majority* of Dr. Murray's cases belong, although no bacteriological data are reported) can safely be nursed in general wards without showing any tendency to spread.

What, then, is the explanation of Dr. Murray's favourable experience? Excluding all cases with raised temperature or septic foci on admission, the groups selected by him for study comprise (*a*) cases with or without minor intervention, such as low forceps or simple perineal repair; and (*b*) cases handicapped by cardiac or renal disease, by ante-partum or post-partum haemorrhage, by slight degrees of pelvic contraction, and by certain obstetrical manipulations, including induction of labour. But having selected these two groups of cases Dr. Murray also eliminated from consideration a group of cases which he calls "suspect" for the reason that they were specially prone to become septic. The "suspect" cases, we are told, were for the most part sent into hospital by doctors, and included cases of accidental haemorrhage, placenta praevia, contracted pelvis, etc.

We find it hard to discriminate between the obstetrical complications in Group B and in the "suspect" group, and we submit that the more favourable experience in 1929 may be due, in part, to unconscious favourable selection in the 1929 cases belonging to Group B. Secondly, it is to be noted that the incidence of sepsis diminished in the isolated "suspect" group from 12.4 in the control period in 1928 to 6.9 during the experiment in 1929; this improvement is attributed by Dr. Murray to intensive supervision and nursing. Does it not follow that the "clean" cases, which remained in the general ward, being also under particular observation, profited to at least as great an extent from the same influences? Thirdly, in view of the known variations in the sepsis rate in institutions, it is probably unsafe to generalize on the limited basis of a comparison between two successive years.

The evidence discussed under the heading "Throat carriers of the haemolytic streptococcus" appears to us of subordinate value. The number of carriers of haemolytic streptococci—68 per cent.—amongst a body of healthy attendants seems abnormally high in the absence of an outbreak of sore throat. The question arises whether the haemolytic streptococci isolated can be considered identical with *S. pyogenes*, the cause of severe puerperal fever. As to the author's admission that a case of acute sore throat constitutes a danger in a maternity ward, it is surely impossible to-day that such a person should be permitted access to a parturient woman. If danger there be from this source, it is the apparently healthy ambulant throat carrier of *S. pyogenes* who is to be dreaded.

To summarize, we beg to record our unstinted admiration of the methods and results of Dr. Farquhar Murray and his colleagues, but to maintain an open mind, on the evidence available, with regard to the explanation of his success.—We are, etc.,

St. Bartholomew's Hospital, E.C.1, May 7th. H. BURY-WHITE, R. R. ARMSTRONG.

GLANDULAR FEVER.

SIR,—I was pleased to find that so competent an authority as Dr. Tidy (*Journal*, May 10th, p. 881) has confirmed the suspicion which I had had for some weeks that glandular fever is much more prevalent than is generally supposed. Although I have been familiar with the literature of the subject for several years, as my summaries in the *Medical Annual* since 1923 can testify, it was only last month that I actually recognized as glandular fever some cases which had been sent to the Western Hospital certified as typhus in two instances, and as scarlet fever in another. The diagnosis in each case was rendered difficult by the late development of the glandular swelling. The occurrence of this at once prompted a haematological examination, for which I am indebted to Dr. J. E. McCartney; he reported a condition of infective mononucleosis. I have no doubt, however, that I have previously seen many cases of glandular fever without identifying them, just as before 1905, when I first became familiar with Vincent's angina, I had seen several cases which, on retrospective consideration, were probably examples of that condition, but which I had not learnt to recognize. Many others have doubtless had a similar experience.

In its slight but undoubted degree of contagiousness, its tendency to appear in sporadic as well as in epidemic form, and the long subsequent period of depressed health which Dr. Tidy has emphasized, glandular fever resembles the epidemic diseases of the nervous system. The question therefore will doubtless arise of making glandular fever a notifiable disease and admitting patients suffering from it to isolation hospitals.

I take this opportunity of referring those interested in the subject of glandular fever, which appeals alike to the clinician, pathologist, and epidemiologist, to the excellent *monograph*[1] *recently published by Dr. E. Glanzmann* of Bern, who shows an exemplary appreciation of the labours of British workers in this field.—I am, etc.,

London, S.W.6, May 10th. J. D. ROLLESTON.

SIR,—For the second time in eight years I have had to contend with a small epidemic of mild glandular fever at Repton. This occurred last term, and after reading Dr. Letheby Tidy's article last week I write to record a few personal observations.

The infectivity of the disease is very mild, even in a school house where fifty boys are congregated together. It is possible that in view of the low virulence of the infection many cases go unobserved. No cases have occurred in a boy over 16 years of age, but the older a boy is the more severe are his symptoms. The left parotid gland is often affected first, giving rise to a diagnosis of mumps in the original patient. The glands affected are nearly always on the left side of the neck, and in mild cases there is no following infection of those on the right side. In families of several children where one child has developed glandular fever I have only seen the infection passed on once. This was in a family of six small boys, where one only developed the disease a week after his brother.—I am, etc.,

Repton, Derby, May 12th. RONALD HODSON.

TREATMENT OF MAMMARY CARCINOMA BY RADIATION.

SIR,—Sir G. Lenthal Cheatle's lecture on this subject, published in the *Journal* of May 3rd (p. 807), is of great interest to professional radiologists, coming as it does from the pen of a distinguished surgeon. Perhaps you will permit me to make a few comments from the point of view of one who has for twenty years been concerned with the radiation treatment of breast cancer.

First, as to points of agreement. Sir Lenthal Cheatle calls attention to the prevalent practice of increasing the dose if treatment seems to be ineffective; he expresses the view that in many instances reduction might be more successful. There is no doubt in my mind that over-dosage is more common that under-dosage. With the apparatus of twenty years ago, incapable as it was of delivering a large dose in a short time, the results were often quite as good as they are now, and patients were never made *ill* by the treatment. I hasten to add that apparatus capable of delivering concentrated doses of very penetrating rays is an essential part of the equipment of a modern radiologist. It will sometimes relieve pain when small repeated doses are ineffective, and is the only form of treatment which does any good in mediastinal growth, in the swollen "fore-quarter" which follows invasion of the axillary and cervical regions, and in metastases attacking bone.

The lecturer laid stress on a wide area of irradiation, pointing out that no one can say from clinical investigation exactly where cancerous cells are located. He also called attention to the experimental work of Professor Russ, which showed that previously irradiated tissues acquired an increased resistance to implanted cancer. This necessity for wide fields has always been present to my mind. At a discussion at the Royal Society of Medicine I once heard the late Dr. Ironside Bruce say: "A widely opened diaphragm; a long anticathode skin distance; a shield over the patient's face; and the more surface your rays cover, the better." To my mind, this dictum remains good at the present day, certainly so far as prophylactic work is concerned. It implies that the actual quantity of rays falling on any given area of skin is very small—so small that no "direct lethal action" upon carcinoma cells can be conceived of as possible. Therefore, if good effects are clinically proved, they must be due in large measure to a stimulation of the local and general resistance.

There are, however, some statements made by Sir Lenthal Cheatle with which I cannot agree. If I preface my remarks by saying that during the past two decades I have dealt with thousands, rather than hundreds of cases, I do so in modesty, because, while Sir Lenthal has no need to refer to his experience, I feel that, in disagreeing with him, I must state my credentials. He says that cancers of the breast do not as a rule regress with external radiation, and that when they do they are also highly anaplastic, so that the prognosis is, in such circumstances, grave. My own experience is that most breast carcinomata can be made to diminish in size, and many to disappear, by comparatively small divided doses of *x* rays of medium quality. In the hospitals to which I am attached it is usual to send patients for a two to three weeks' course of pre-operative radiation. At the end of this time, short as it is, the tumours are usually smaller, and, more important, the pathologist's report is to the effect that the carcinoma cells show degenerative changes. The difference between my experience and that of Sir Lenthal Cheatle may be due to the dosage employed, which, in my cases, is certainly much less than is customary, and has even been ridiculed by some of my colleagues as a mere playing with, rather than a serious use of, *x* rays.

The lecturer points out that it is by no means certain that expensive radium bombs for external radiation will give better results than deep *x* rays; he adds that "the interstitial application of *x* rays is at present impracticable." This latter statement is correct only in the sense that it is not possible to get an intense interstitial action comparable with that of buried radium tubes without at the same time having an external source of radiation. But it is an easy matter to intensify the action of an external beam of *x* rays in any desired locality. This can be done by utilizing the phenomenon of secondary radiation. The heavier elements when struck by *x* rays emit a specific or characteristic radiation depending upon their atomic weight. In a paper read before the Electro-Therapeutic Section of the Royal Society of Medicine in 1912, I discussed this subject at length in its possible therapeutic applications, and showed that if a finely divided metal such as precipitated silver were injected into a tumour, each minute particle emitted secondary *x* rays in all directions when excited by a primary beam outside the body. These rays I called "pandrastic" to indicate their universal distribution. If I have not followed this up to any great extent in practice, it has been due to a wholesome dread of trauma, even a needle puncture in malignant growths. If, however, Moppett's observations on the specific effects of different wave-lengths should be confirmed, the subject of secondary rays may assume great importance, since the introduction of suitable materials into and around tumours would at one and the same time provide interstitial action and a choice of wave-lengths.—I am, etc.,

London, W.1, May 3rd. F. HERNAMAN-JOHNSON.

BLOOD CULTURE IN UNDULANT FEVER.

SIR,—The reports in the *Journal* of May 10th of five cases of undulant fever, four at least of which were apparently due to infection with *Br. abortus*, will be read with interest by all who are anxious to ascertain the frequency of this disease in Great Britain. Over twenty cases have now been reported, but in only two of them has the causative organism been isolated—once from the blood and once from the urine. In the remainder the diagnosis has been based on the results of the agglutination reaction. From the bacteriological point of view it is of importance to determine the exact type of the infecting organism, and this can be done only by its recovery from the patient. Since there still seems to be a considerable amount of uncertainty as to the best method to be adopted for this purpose, I venture to make the following remarks.

The blood should be withdrawn during a pyrexial period, and should be distributed into flasks of a suitable medium. Probably Stafseth's liver infusion broth is the most satisfactory; for a description of this medium reference should be made to Duncan's article in the *Transactions of the Royal Society of Tropical Medicine and Hygiene*, 1928, xxii, 269. Plain ordinary heart extract broth adjusted to *p*H 6.6 to 7.0 may be used. Two flasks should be inoculated: one of them should be incubated aerobically, in case the infecting organism is of the *melitensis* or of the porcine *abortus* type; the other should be incubated in a closed jar containing air, 10 per cent. of which has been replaced by CO_2, in case, as is most likely in this country, the infecting organism is of the bovine *abortus* type. The simplest way of providing the requisite CO_2 content is to connect the jar to a filter-pump, reduce the pressure by 76 mm.—1/10 of an atmosphere—and then run in CO_2 from a cylinder or from a Kipp's apparatus containing HCl and marble till the pressure is restored to that of the atmosphere. The flasks should be incubated for three weeks, subcultures being made on agar plates every five days.

It may be pointed out that CO_2 is absolutely essential for the growth of the bovine *abortus* type, and that a reduced oxygen pressure, as was used, for example, by Dr. Baxter, is not sufficient to ensure growth. If routine blood cultures were made according to this technique on all patients giving a positive agglutination reaction to *Br. abortus*, I feel sure that the infecting organism would be recovered in a considerable proportion of cases.—I am, etc.,

London School of Hygiene and Tropical Medicine, May 10th. G. S. WILSON.

BRUCELLA ABORTUS INFECTION.

SIR,—In view of the cases of *Brucella abortus* infection reported in the *Journal* of May 10th, and the editorial comments thereon, it seems desirable to refer to a case I attended in 1896 in Plymouth.

The patient, aged about 25, had recently passed into the Indian Medical Service, and had been through a special course of instruction at Netley in preparation for his duties. He came home to Plymouth before sailing for India, and was seized with a febrile attack. His brother, a medical practitioner in this city, asked me to assist him in the attendance. His symptoms were those of

an acute febrile illness, with a temperature of the typhoid type and abdominal distension: we considered the case one of typhoid fever. At the end of the third week the temperature fell to normal and his symptoms subsided, to be followed after a few days by a relapse lasting about a week, accompanied by pain in the right hip. A second similar attack with joint pain succeeded recovery from this relapse. By this time we were becoming doubtful of the correctness of our diagnosis, when fortunately he was seen by a retired Indian Medical Service officer, who recognized the disease as undulant fever. A prolonged convalescence followed the onset of recovery ensued.

The origin of the infection was a mystery. The patient had never been out of England, and the suggestion was made that possibly he might have accidentally contracted the infection during his work in the bacteriological laboratory at Netley.—I am, etc.,

H. W. WEBBER.

Royal Naval Hospital, Plymouth, May 12th.

STERILITY IN WOMAN.

SIR,—There is an interesting side-issue to the discussion on sterility started by Mr. Leith Murray's letter (April 26th). It seems to be becoming the practice among gynaecologists to advise that the seminal fluid be examined as a routine in the investigation of cases of sterility. I wish to question both the practical utility and the desirability of this examination, and, indeed, to urge that it should not be carried out unless the husband asks that it should be done. Mr. Leith Murray mentions one or two cases of threatened suicide in men who have been informed, as the result of this examination, that they are incapable of procreation. Mr. Connell (May 3rd) says that we can easily understand this (as indeed we all can), and proceeds to recommend that in all cases the semen should be examined before subjecting any woman to operation. In cases where operation is advised for a definite lesion discovered on examination, surely it is unnecessary to demand that the husband should consent to an examination some of the details of which may well appear to him to be revolting. In cases where nothing is found in the woman to account for the sterility but where dilatation is advised as a sort of forlorn hope, then I consider that the risk and inconvenience associated with this operation (which is unlikely to be successful in any case) are trifling and not worth considering when compared with the risk of humiliation and domestic unhappiness that may follow a report adverse to the husband. It may be argued that the man can refuse to have this examination made; he is unlikely to refuse, however, even if unwilling, for two reasons—first, because, if he trusts his doctor, he is likely to follow his advice, and secondly, because to decline examination is almost tantamount to admitting that he fears to face the verdict. If it were merely a question of barrenness to both that the "blame" should be laid on the responsible partner, it would be comparatively easy to do so. But I submit that there is little to be gained by this straining after scientific accuracy, and a risk that much harm may be done; for it is much more humiliating to the man (or him (and his wife) to be assured that he is incapable of procreation than it is to the woman for her to be informed that she is unlikely, as the result of conditions found on examination, to be able to have children. A woman who comes for examination on account of sterility wants to know "if there is anything wrong with her," and, if there is, what can be done about it; she rarely, in my experience, makes the suggestion that her husband should be examined. I therefore advocate that, except in special circumstances, the semen should only be examined when the husband asks for it.—I am, etc.,

Leicester, May 5th. T. C. CLARE.

HYPOGLYCAEMIA.

SIR,—The illuminating article on chronic hypoglycaemia by D. P. J. Cammidge in your issue of May 3rd (p. 812) is of particular interest to me. For some years my attention has been directed to what I can best describe as an acute manifestation of hypoglycaemia. Of the 26 such cases of which I have notes in only 3 have I been able to estimate the blood sugar at times other than those when acute symptoms have occurred. Although in each of these hypoglycaemia persisted between the acute manifestations, my investigations do not permit me to say that hypoglycaemia was chronic in every case. I need only quote one case in detail, as the clinical symptoms are precisely the same in every case.

The patient was a male, aged 31. His family history revealed nothing of importance. In childhood he had had the usual exanthemata—including diphtheria at the age of 5—and recurrent attacks of acute follicular tonsillitis; the tonsils were not removed. At the age of 11 he had an acute abdominal illness—probably an acute appendicitis. At 14, for a period of a few weeks, he had eructations of sulphuretted hydrogen. This occurred at school, and was associated with a yellow vision. He did not report it, and so was not seen by a doctor. From 19 onwards he suffered from severe hunger pain on and off for periods of several months at a time. He was very thin. There was epigastric pain of an aching character with the first few deep breaths on awakening in the morning. At 25 he suffered severe pain immediately after food, and saw a physician. At this time there was gastric dilatation and succussion, which attracted the patient's notice when he turned over in bed, and he described it as resembling the disturbance of a rubber hot-water bottle.

After he had led a stomach-tube life for a year laparotomy was performed. The surgeon's notes on the operation show that there was an enormously dilated stomach, extending down to the pelvis. No duodenal or gastric ulcer was found, and no evidence of mechanical obstruction of the pylorus or duodenum. There was no report on the appendix, which was apparently not removed. A posterior no-loop gastro-jejunostomy was performed. The operation almost entirely relieved the patient's digestive troubles, but a few weeks later hypoglycaemic symptoms appeared. About half an hour after a short spell of very active exercise the patient "felt faint," and had to sit by the road-side. During such an attack he had the following symptoms: slight hypogastric discomfort, pallor, sweating, and a sense of extreme muscular weakness associated with a fine tremor of the hands, slight dyspnoea, and a craving for food (not hunger pain). As time went on these attacks recurred from time to time; they were precipitated if the patient went without food, or if he took coffee or strong tea, and they were always associated with a craving for food, especially starches and sugar.

When I saw him he was aged 30. He was a tall, spare man, with musculature lacking in tone, and long-chested; the tonsils were flat, the fauces injected, and the tongue slightly coated. The first heart sound was accentuated at the apex; the systolic pressure was 105. His urine contained excess of phosphates; no sugar. The resemblance of these attacks to the symptoms of insulin hypoglycaemia led me to test his sugar tolerance. Fasting it was 0.08. At the end of half an hour it had risen to 0.14, and returned to 0.08 at the end of two hours. A few weeks later I had an opportunity of seeing him in an attack. The symptoms were such as I have already described. His systolic blood pressure was then 95, and his blood sugar 0.06.

Among my other cases was a lady aged 38 who, a few months previously, had had a partial gastrectomy done. She was picked up unconscious in the street. A doctor who saw her on the spot found her collapsed and pulseless; her pupils were slightly dilated, and there was no corneal reflex. I saw her half an hour later. She was then conscious, but profoundly shocked, with a pulse of 140, which was of the soon full, soon empty type. Her blood sugar was 0.05; systolic blood pressure 110. I gave her one pint of 5 per cent. solution of dextrose, which produced a most dramatic recovery. She was then given some well-sweetened cocoa, and half an hour later she insisted on going out and completing her shopping expedition. I recommended her always to carry barley sugar in her handbag, and to eat some when she felt one of these attacks threatening. Several attacks were thus averted. Some eighteen months later, with the premonitory symptoms of an attack, she found herself without her barley sugar. The attack developed, and she was taken unconscious into a London hospital under conditions similar to those which I have described.

In only 7 of my 26 cases have I been able to get an estimation of the blood sugar during an attack, and, therefore, hypoglycaemia as a cause of the symptoms is only supported in the remaining cases by the clinical symptoms and their disappearance on the exhibition of carbohydrates. In only 3 cases have I been able to get blood sugar tolerance tests. The fasting blood sugar was in all three below 0.1—one rose to 0.2 at the end of three-quarters of an hour, and the others were below 0.14 in three-quarters of an hour. The association of low blood pressure with the symptom complex is interesting in view of the relationship between the adrenal gland to blood pressure and sugar metabolism.

Of the 26 patients in this series, 17 had undergone operations involving the stomach, duodenum, or gall-bladder;

19 were men, and 7 women. The age incidence of the operation cases was determined by the age at which the operation was performed, and in every case the onset was within three months of the operation. The age incidence of the non-operation cases (5 men and 4 women) varied between 23 and 45. The symptoms in every case were slight epigastric discomfort, muscular weakness, slight dyspnoea, rapid pulse of the soon full, soon empty type, some sweating, and tremor. In no case have I found glycosuria. The symptoms always disappear on the exhibition of carbohydrates.—I am, etc.,

THOMAS E. A. STOWELL.
London, S.W.1, May 6th. M.D., F.R.C.S.

TREATMENT OF ENDARTERITIS OBLITERANS.

SIR,—The paper by Dr. Schwartzman (May 10th, p. 855) raises once more the question of the treatment of intermittent claudication (or, to use a better term, endarteritis obliterans) and of the allied arterial syndromes—angina pectoris and mesenteric arteritis. Unfortunately Dr. Schwartzman bases his observations principally on the amelioration of the subjective symptoms, and neglects the only procedure by which the action of a therapeutic agent on intermittent claudication can be studied—namely, the following up of the increase of the oscillometric index, a method strictly objective and indispensable for the study of patients with endarteritis obliterans.

In my paper in the *Journal* of February 8th (p. 234) I referred to the remarkable results obtained with pancreatic extracts deprived of insulin. Although it would be interesting to compare the action of these pancreatic extracts with that of the muscular extract utilized by Dr. Schwartzman it must be remembered that the efficacy of the pancreatic extracts, apart from certain physiopathological considerations, has in its favour the fact that the already numerous observations which have been published on that method are based, not on the vague amelioration of subjective symptoms, but on the distinct increase of the arterial permeability which is manifested, with mathematical precision, through the oscillometric exploration.—I am, etc.,

London, W.1, May 9th. A. P. CAWADIAS.

ASYLUM MEDICAL OFFICERS AND RESEARCH.

SIR,—As one of the members of a subcommittee convened by the British Medical Association to consider the status and conditions of service of asylum medical officers, may I be permitted to make a few observations, which seem peculiarly relevant at the present time?

The modern mental hospital, equipped as it is with elaborate laboratory and clinical facilities, offers opportunities for medical investigation and research which were undreamed of by our predecessors. Moreover, the establishment of the diploma in psychological medicine has awakened in many asylum medical officers an enthusiasm and interest which is abundantly reflected in their contributions to current medical literature. But what of the future of these clinical and laboratory workers? The higher posts in the mental hospital service are purely administrative in nature, and a medical superintendent of a large institution must either neglect his institution or say good-bye to medicine. Such positions hold little attraction for men whose interests are primarily in the wards or in the laboratory, but there is no alternative in our present system. Few men can afford to ignore completely the material side of life, be they ever so keen on their profession.

In an able and illuminating paper recently read before the Royal Society of Medicine,[1] Dr. Mapother, sketching the psychiatric system in America, observes that "scientific work is encouraged by establishment, just below the superintendency, of three equal positions—that of administrative assistant, clinical director, and pathologist—each providing a satisfactory career." Dr. Mapother also stated that "it is not better buildings or maintenance that constitute the real difference of American psychiatry. The difference depends on the medical spirit dominating it, and consequent preoccupation with treatment and research." Much has already been accomplished in our public institutions towards kindling this spirit among the younger generation of doctors, but unless the movement is to prove a failure, suitable inducement must be provided in the nature of higher appointments of a purely medical nature. The administrative and scientific minds are disparate; there is room for both in mental hospitals.—I am, etc.,

Brentwood, May 4th. THOMAS D. POWER, M.D.

[1] *Lancet*, April 12th, p. 851, and *British Medical Journal*, April 19th, p. 743.

SWELLING OF FEET AND ANKLES WITHOUT ALBUMINURIA OR GROSS ORGANIC DISEASE.

SIR,—I read with interest the article on this subject by Dr. A. Arnold Osman in your issue of April 26th (p. 789). During nine voyages to Australia as ship surgeon (that is, passing through the Tropics eighteen times), I have been consulted by between seventy and a hundred patients with this complaint. They were all, without exception, of the female sex, in spite of the fact that usually there are more male than female passengers among the third class. Most of them were between the ages of 16 to 25, although a few were middle-aged women. No child of either sex was seen suffering from this condition. With the exception of five or six cases they were all third-class passengers, but, in the ship I was in during most of this period, there were about seven times as many third-class as first-class passengers. All cases were examined for heart lesions and albumin in the urine, and all proved negative. No treatment other than resting with the legs raised was instituted, and they all recovered in seven to fourteen days when cooler weather was reached.—I am, etc.,

May 5th. H. M. ROYDS JONES.

FEES FOR PATHOLOGICAL TESTS.

SIR,—At the annual meeting of the governors of Charing Cross Hospital Pathological Institute, Mr. George Verity is reported as having stated that "the Pathological Institute was doing untold good in examining patients who are not of necessity eligible for treatment in hospital," but that "the work will be in jeopardy unless £1,000 is quickly subscribed towards it." May I beg the courtesy of your columns to point out that similar work with similar results is being done in the pathological departments attached to most of the voluntary hospitals throughout the country; none of these hospitals have, however, as yet, found themselves under the necessity of appealing to the general public for funds in support of this work.

The fees charged by the Charing Cross Hospital Institute of Pathology for pathological examinations are below those charged by any similar institution in this country, and are set at a level at which, without subsidies from outside sources, it is impossible for them to be performed other than at a loss. It is not surprising to anyone engaged in similar work that the authorities of the Charing Cross Institute of Pathology, having set their fees at this low level, should find themselves in need of a subsidy. As to the justification of an appeal to the public for funds to enable the continuance of this policy of fee-cutting in competition with the pathological services conducted by other voluntary hospitals, I leave your readers to judge.—I am, etc.,

S. C. DYKE,
Wolverhampton, May 7th. Secretary, The Association of Clinical Pathologists.

ANTIMALARIA MEASURES.

SIR,—In his letter published on April 12th, Lieut.-Colonel C. A. Gill defends the existence of a new party amongst malariologists possessed of doctrines so widely differing from its compeers that it has considered it necessary to employ the distinctive term "modern" and, to ensure its own identity, has dubbed the body it leaves "old." In accord-

ance with the practice of politicians, he states the ground upon which the withdrawal has been found necessary. The reasons are very pronounced. It is quite a usual weapon for parliamentary antagonists (in parliamentary language) to declare that such-and-such policy has not been fulfilled; but, in this case, an advance upon this method has been made. It is asserted that the policy of the so-called "old" party has been supported by "unsubstantiated claims" in practice of antimalaria measures, and that at its hands "incalculable harm" has resulted.

In view of the fact that Lieut.-Colonel Gill's letter is a reply to that of Sir Malcolm Watson's letter published on February 8th, where was given a large—yet not exhaustive—list of splendidly successful antimalaria works, Lieut.-Colonel Gill's assertions would have had greater weight were he to have specified instances. So far as facts are open to the profession and the lay public, there has been no neglect by the so-called "old" party in readily adapting antimalaria measures to knowledge gained locally or in any part of the world. Indeed, there seems to be no sound reason to believe that the giving of a new name to this group of malariologists will have more practical effect in preventing malarial diseases than has followed the obliteration of the name Mian Mir in favour of Lahore Cantonment.

As to the "modern" school lacking support in research as being routed by astute politicians of Lieut.-Colonel Gill's fancy, he has apparently forgotten that in India—whence this "modern" group has evolved—irrespective of work fulfilled in provincial institutes, there has been at disposal from the Government of India funds a sum of £33,000 annually since 1913-14, which has, or should have been, specially devoted to research in tropical diseases, of which, certainly, malaria investigation has not been omitted. Substantial grants in addition have been made within the last few years. Further, since 1910, numerous antimalaria committees have been formed, and medical officers have been deputed for long periods on special duty—including a chief malaria medical officer for the Punjab.

That further research in malaria causation would be advantageous may well be true, and equally so this may be said of numerous other factors connected with curative and preventive medicine, but to advance the mere theory or hope that in an undetermined future, this may be so happily fruitful as to demand radical departures from present procedure either in cure or prevention cannot warrant the failure to use such measures as are available, and have hitherto proved successful in saving human life.

I suggest that instead of the term "modern" by which the "new" party elects to be identified, it would be more appropriate to recognize it as malariologists—species "wait-and-see." The report on antimalaria measures in Kenya illustrates fully the temporizing policy of the "modern" party. It is there announced that "intensive research along other lines is more than ever necessary, for *no* antimalarial method capable of being applied by sanitarians in *all* malarious areas" (italics not in original). To obtain so valuable a panacea is no mean ambition, having regard to the various physical and climatic conditions ordinarily encountered. Meanwhile, far from advising a practical organization upon whose work a large area of the Empire can rely for future health and prosperity, that report merely illustrates the possession by the author of an obsession for research and accompanying high hopes. This phase, doubtless, is praiseworthy ambition when allowed to prevail in due proportion, but when accompanied by lack of due recognition of several no less operative factors must mislead and cause—" I thank thee,' modern party, "for teaching me that word"—*incalculable harm*.—I am, etc.,

W. G. KING, Colonel I.M.S. (ret.).

Hendon, N.W.4, May 5th.

SIR,—After seeing the letter by Lieut.-Colonel C. A. Gill, I.M.S., on malaria control (April 12th, p. 718), and looking up Sir Malcolm Watson's letter in your issue of February 8th (p. 259), which I missed owing to being at that time on the homeward voyage, may I beg space in your columns to reply to Colonel Gill?

1. It may be that originally malariologists claimed that "if all mosquitos could be destroyed, malaria would be completely abolished," but surely Colonel Gill must be aware that, for the last twenty years, species control has been in practical use, and by it the old school, of which Sir Malcolm Watson is the greatest British exponent, have achieved the results which Colonel Gill impugns. Who, then, is the "high authority" who still demands the killing of all mosquitos?

2. I emphatically deny that most exponents of the so-called old school are "completely satisfied with the state of scientific knowledge attained some thirty years ago," even in respect of mosquito bionomics in their strictly antimalarial applications. Colonel Gill has only to peruse any number of the *Review of Applied Entomology* (Series B) to see how much is still being done throughout the world on this subject, and it should not be beyond him to visualize the far-reaching practical applications which research on these lines will furnish in the hands of the old school.

3. The views expressed by Colonel Gill, however, could have been no more than the subject of an instructive academic discussion in your columns were it not for the very serious and definite charge which he makes against the old school of endeavouring to establish their viewpoint "by means of unsubstantiated claims regarding their successes." As I feel sure that Colonel Gill would regard me as belonging to the old school (though I should not so describe myself, and do not entirely agree with the views of Sir Malcolm Watson as to the futility of improvements in diet and general sanitation) I am forced to take up the matter in my own defence, as now lying under the charge of having made "unsubstantiated claims" regarding my successes by antilarval methods of control. Now malariologists who, unlike Colonel Gill, work largely for commercial interests, are not always in a position to publish their results. In my own case I have only been able to do so in respect of one control carried out for the Kepitigalla Rubber Estates, Ltd., and certain controls carried out for the Bengal-Nagpur Railway in 1925-26. If my published figures regarding these controls are "fakes" then I stand convicted of having misled the subordinate medical staffs of these concerns over diagnosis and records, of having furnished false figures to the Inspector-General of Hospitals, Ceylon, to the Chief Medical Officer of the Bengal-Nagpur Railway, and to the Railway Department of the Government of India (who authorized the publication of, and themselves printed, my railway results), as well as to the recent Whitley Commission on Indian Labour, who called officially for more recent Bengal-Nagpur Railway figures than I published three years ago.

The medical entomologist has not the British Medical Association to appeal to when thus attacked, so, leaving Sir Malcolm Watson and others of the old school to defend themselves, I must ask Colonel Gill to withdraw, after any investigation he may desire, his statement regarding "unsubstantiated claims," at least as regards my own work.—I am, etc.,

Harpenden, April 30th. RONALD SENIOR WHITE.

MEDICAL PRACTICE IN SOUTHERN RHODESIA.

SIR,—May I draw the attention of men who are well qualified in medical and surgical practice to the excellent opportunities offered by the posts in Southern Rhodesia now advertised in the medical journals? The position carries a salary of £500, rising to £650, per annum as Government medical officer, with the right of private practice, a feature which, of course, makes all the difference to these posts. Southern Rhodesia has a delightful and healthy climate, and the country is a most attractive one in which to settle. There are very good schools. Medical men who have been in practice there for a number of years speak very highly of the prospects, both from a professional and a social point of view.—I am, etc.,

R. A. ATKINS, M.D.

Office of the High Commissioner for Southern Rhodesia, Aldwych House, London, May 10th.

Medico-Legal.

"MANIPULATIVE MASSEURS" SENTENCED.

ABRAHAM COHEN, alias Max Conn, and Ramos Luro, "manipulative masseurs," were found guilty at Nottingham Quarter Sessions, on May 2nd, of obtaining money by false pretences and conspiracy to defraud. The prosecution alleged that the prisoners had professed to cure all kinds of ills by massage and application of an oil which they sold, and that in nine months last year they had taken £3,600 from hundreds of poor people who were suffering from incurable ailments.

Mr. R. G. Hogarth, a former President of the British Medical Association, stated with reference to a patient whose left leg was shorter than the right, that massage or rubbing with oil would not have the slightest effect on the condition, which was incurable. Similarly, rupture would not be cured by the treatment administered by the accused; the proper treatment was operation. In the course of his evidence Mr. Hogarth said that in a book issued by the prisoners he had read that the "magic" of Max Conn cured cases of cancer, diabetes, epilepsy, heart disease, kidney disease, tuberculosis, varicose veins, and so forth. Dr. A. C. Reid, referring to cases of blindness treated by the accused, and Mr. H. B. Tawse, to cases of deafness, said that the patients would not derive the slightest benefit from the measures adopted. For the defence it was stated that a dozen witnesses would be called to say that they had derived benefit from the treatment received at the hands of the accused. Cohen, giving evidence on his own behalf, denied having used at any time the phrase "guaranteed cure"; he had not gone beyond saying "I am hopeful that I can put you right."

After the jury had brought in its verdict, the Recorder said that the prisoners had been found guilty of conduct that was heartless and cruel to a degree. It was difficult to discover any extenuating circumstances. Cohen was sentenced to twelve months' imprisonment with hard labour in respect of the charge of false pretences and twelve months' imprisonment for conspiracy, the sentences to run concurrently. Luro was sentenced to nine months' imprisonment with hard labour for false pretences and twelve months' imprisonment for conspiracy, the sentences to run concurrently. The prisoners were also ordered to pay £250 towards the cost of the prosecution.

Obituary.

MURDOCH CAMERON, M.D., C.M., LL.D.,

Late Regius Professor of Midwifery, University of Glasgow, Gynaecologist to the Western Infirmary, and Senior Obstetrical Physician, Royal Maternity Hospital.

PROFESSOR MURDOCH CAMERON died of a cerebral haemorrhage, in a nursing home in Glasgow, on April 28th, in his 85th year, and through his death the art of obstetrics has suffered a severe loss. In 1926 failing health compelled him to resign the Regius Professorship of Midwifery in the University of Glasgow, an appointment to which he succeeded on the retirement of Professor William Leishman in 1894.

Murdoch Cameron was educated and spent the whole of his professional life in Glasgow. He graduated in 1870, and took his M.D. degree two years later. He settled in practice in the Townhead district of the city, in close proximity to the Maternity Hospital, and from the first devoted himself to the study of midwifery. In 1888 he was appointed visiting physician to the Glasgow Maternity Hospital, and he maintained an unbroken association with the institution until 1920. It was there that he performed his series of twelve consecutive successful Caesarean section operations, which established the procedure on a sound and scientific basis in this country, and removed the dread with which the operation had been previously regarded. Prior to this the performance of the operation had been entrusted to general surgeons, whose knowledge of midwifery was of the scantiest, for the simple reason that obstetricians were not in the habit of performing major surgical operations. The results were almost uniformly fatal, and it took a bold man, in face of this, to persuade himself that he could attain success where so many others had failed. But Murdoch Cameron was an optimist who never envisaged defeat. His first success was no mere stroke of luck or the action of an ignorant and foolhardy young man. Long before he had the opportunity of performing his first Caesarean section he had made up his mind that he would seize the first chance of doing it. Not only so, but he had carefully devised his method of operating, and when his chance came he was ready for it. The first operation almost ended in disaster. Arrangements had to be made hurriedly. The operating room—it could hardly be called a theatre—was cold, and in order to heat it methylated spirit was poured on to a tray and ignited. This caused an explosion of ether vapour in the middle of the operation, and fire broke out in the room. Cameron stopped his operation, assisted in extinguishing the fire, and then finished the operation, apparently unmoved by what had happened. At that time he was assistant to Professor Leishman at the University. With justifiable pride he told Leishman of his success, and received from him the chilling advice: "Well, Cameron, you have had 100 per cent. of successes. Don't do any more; you may spoil your record." The operation is now one of the commonplaces of obstetrical practice, and, in carefully chosen cases, gives as good results as those of ovariotomy.

The position of gynaecology has been revolutionized in the last forty years. It is difficult for those trained under present conditions to realize that in those days a man might be a professor of diseases of women and never have done any but the most minor of gynaecological operations. Leishman did not operate, and it was only when Murdoch Cameron succeeded to the chair, at the age of 47, that he got his first opportunity of performing major gynaecological operations. Most men at that age would have shirked the responsibility, but such a thought never entered his mind. He was naturally dextrous with his hands, and rapidly became a skilled operator. No emergency ever shook his confidence or disturbed his equanimity. With him to think was to act, and in a difficulty he could act with astonishing rapidity.

It was as an obstetrician that Murdoch Cameron did his best work. From his long association with the Glasgow Maternity Hospital he had a unique experience of the practical difficulties of obstetrics. He had a natural mechanical genius, and was full of original devices of his own for dealing with the emergencies that occur during labour.

He was endowed with a splendid physique, and enjoyed excellent health throughout his long life. His recreation was fishing. Apart from the loss of his wife about thirty years ago, his family life was singularly happy. His chief source of joy was his association with his son, Dr. S. J. Cameron, who assisted him both in his University work and in the Western Infirmary, and who, a few years ago, succeeded him as gynaecologist to the Western Infirmary. Murdoch Cameron was by nature a contented, happy, and friendly man, always willing to help a struggling junior, but when his combative instincts were aroused he could hit out vigorously. The writer of these notes worked with him for twenty years, and during the whole of that period never had an unpleasant word from him. When he retired from his professorship the University conferred on him the degree of LL.D.

A. N. McL.

AN OLD STUDENT writes:

Until he retired from the chair—indeed, probably to the end of his life—the professor was just a big, boisterously playful, incorrigible schoolboy. Some there were who took offence at his manner. All his faults lay on the surface. He was a fighter, but he fought clean and straight, and even his opponents had to pay tribute to his upright and honest character and the unselfishness of his motives. He was really one of the softest-hearted of mortals, who attempted to hide his kindly nature under a show of gruffness. His unique experience of difficult obstetrical conditions in the rachitic slum dwellers Glasgow made him an authority in his subject; in f he may be said to have founded a Glasgow school of m wifery, and though he was far from being a prolific writ many of his old students will detect in the most up-to-d practical methods and suggestions the practice and ad of their old teacher. He was always ready to help stude and practitioners in difficulties, and many of us will l his name in green memory.

H. J. B. FRY, M.D.,

Pathologist to the Research Institute, Cancer Hospital, London.

DR HUBERT JOHN BURGESS FRY, pathologist to the Research Institute of the Cancer Hospital, died there on May 5th as the result of a streptococcal infection incurred in making a post-mortem examination.

He was educated at Charterhouse, where he distinguished himself both as a scholar and as an athlete, and at Magdalen College, Oxford, of which he was a Science Exhibitioner. He took his degree in natural science in 1907, with first-class honours in physiology. He was appointed to an Oxford University biological research scholarship at Naples, as a result of which he published two very thorough and important contributions to zoology, and was awarded the B.Sc. degree. He joined St. Thomas's Hospital, graduating in medicine in 1911, and serving in several of the resident posts before specializing in pathology. He became an assistant and Jenner research scholar in the pathological department of his hospital until, on the outbreak of war, he received his commission in the R.A.M.C.(T.F.). While he was serving as a regimental medical officer to one of the London regiments the adviser in pathology (Sir William Leishman) applied for his transference to the pathological laboratory of one of the hospitals in Rouen. Both there and at Abbéville he conducted researches in influenza, and was one of the first to prepare and use immunized whole blood in the treatment of septicæmia and extensive suppuration. On demobilization he was engaged as pathologist to the central laboratory of the Ministry of Pensions. In 1922 he joined the research staff of the Cancer Hospital, and rapidly made a name for himself as an investigator in cancer. He had previously shown evidence of originality in the department of serology, and his first contribution in the study of cancer was the publication of his well-known serodiagnostic test, which, though not always a certain indication, proved to be easily the most successful method yet introduced. The large number of cancer serums that he examined by means of the Wassermann reaction enabled him to give a clear indication of the relationship between syphilis and cancer of the various organs. His experimental work and his experience of clinical pathology combined to give him a position of authority amongst cancer researchers. His last contribution, given at the meeting of the Leeuwenhoek Vereeniging, on the occasion of the opening of the Paris Cancer Institute, dealt with several cases of carcinoma arising in war wounds. He gave much of his time to committees of the British Empire Cancer Campaign; he was chairman of the editorial committee of the *Cancer Review*, to which he contributed critical reviews, mainly on subjects dealing with serology, heredity, and morbid anatomy; he was honorary secretary to the Investigation Committee and to the Scientific Advisory Committee of the Campaign; and he had a great part in the organization of the London Cancer Conference in the summer of 1928.

He took a very active part in the public life of Welwyn Garden City, where he was a councillor and a magistrate. After the commencement of his illness he was elected chairman of the urban district council. An advanced politician, he had been approached to become a parliamentary candidate, but his crowded life left him no time, nor had he much inclination for such honours. He leaves a widow (Dr. Gladys Mudd-Smith) and three young children. His merits as a pathologist, his strength of character, and his great personal charm brought him hosts of friends, who mourn his loss.

PROFESSOR ARCHIBALD LEITCH writes: I met Fry first during the war, when we were together in a casualty clearing station, and we became friends. When military dispositions separated us I tried unsuccessfully to get him attached to my mobile laboratory, though I was indirectly the means of his being appointed to a laboratory at Rouen. But after we had returned to civil life I was fortunate in inducing him to join Kennaway and myself at the Cancer Hospital. That partnership has been very happy, and the breaking of it has been a sad blow to us. He published many papers of great merit, but they were merely a preliminary, we felt, to greater things. He was an extremely hard worker, and particularly thorough in all that he did. His pleasant, smiling, modest demeanour gave grace to his sturdy independence of judgement and his unswerving devotion to his ideals of duty—professional, social, or political. Everybody loved him.

MR. ERIC PEARCE GOULD, F.R.C.S., writes: It was my privilege to know Fry intimately, both at Charterhouse and afterwards at Oxford. And now that his life has been cut short one feels that his earlier years count for more than in lives lived to their full span. Fry was an outstanding figure at school in many ways, distinguished alike at work and games, with a gentleness of manner that belied his great physical strength, and a humility of mind that matched his industry and independence of thought. He nearly died of appendicitis in his second year, and the daily prayer for Hubert John Burgess Fry in chapel for many weeks fixed his full name indelibly in the memory of his contemporaries; but to his circle of friends he was always known as "Daddy," a tribute to his sturdy solid appearance and to his no less rugged reliable character. No boy can have been better equipped naturally to profit by the stimulating teaching of O. H. Latter, biologist to the school, and under this influence the research mind of which recent years have given such ample proof developed steadily and surely. At Oxford later, as a favourite pupil of Gatch, Haldane, Arthur Thomson, and Gustav Mann, he blossomed into the outstanding figure of his year, and won, as he deserved, the best first class in the honours school of physiology of 1907. He cared nothing for the good opinions of his colleagues, and was entirely free from any worldly ambition. Popularity came to him, he never sought it. And it came to him, as did his success, the one the natural tribute paid to an upright, unselfish, charming character, the other the inevitable reward of industry, painstaking thoroughness, and independence of judgement. In the laboratory, on the cricket field, or in the river, pitting his strength and prowess as a swimmer at the end of a salmon cast against the skill of the salmon fisher on the bank, "Daddy" was always the same—concentrated, cheerful, the very best of good fellows. Whatever be the loss his untimely death may mean to medical research in England, it is the end, to those who were lucky enough to know him, of a friendship that can never be forgotten.

The following well-known foreign medical men have recently died: Professor JOSEPH KÖNIG of Münster University, an authority on the hygiene and chemistry of nutrition, aged 87; Geheimrat ERNST KÜSTER, formerly professor of surgery at Marburg, aged 80; Dr. ADOLFO FLORES, director-general of public health of Bolivia; Dr. ERNST SCHWAB, a prominent consultant at Wilbad, from trichinosis; Professor WILHELM ZANGEMEISTER, director of the Women's Clinic at Königsberg; Dr. ALEXANDER ROSNER, professor of gynæcology at Cracow; Dr. E. FEINDEL, a Paris neurologist, aged 63; Dr. PAUL J. SCHROETER, extraordinary professor of ophthalmology at Leipzig, aged 70; Dr. JOSEPH DE KONINCK, a Belgian alienist; Dr. EUGÈNE DEVIC, an eminent physician of Lyons, aged 72; Dr. JULIO A. BARRENECHEA DIAZ, a Santiago urologist; Professor MATHES, director of the medical clinic at Königsberg, aged 65; Professor RUDOLF WLASSAK, director of the Steinhof inebriate sanatorium near Vienna, and author of a standard work on the alcohol problem; and Professor YAMAGIWA, a Japanese research worker on cancer.

Universities and Colleges.

UNIVERSITY OF LONDON.

AT a meeting of the University Court on May 7th (Lord Macmillan in the chair) the thanks of the Court were accorded to the London County Council for its decision to increase the Council's maintenance grant to the University for the year beginning September, 1930, to £105,000. Thanks were also accorded to the County Borough of Croydon for the renewal for the year ending March, 1931, of its grant of £500.

Applications for the Laura de Saliceto studentship for the advancement of cancer research must reach the University by July 1st. The studentship is of the value of £150 a year for not less than two years. Full particulars can be obtained on application to the Academic Registrar of the University, South Kensington, S.W.7.

UNIVERSITY COLLEGE.

The examination for the Bucknill Scholarship (160 guineas) and for two exhibitions (value 55 guineas each) will begin on June 24th. The subjects of the examination are chemistry, physics, botany, and zoology. The scholarship and the two exhibitions are tenable at University College, London. Entry forms should be obtained from the Secretary of University College not later than June 2nd.

LONDON HOSPITAL MEDICAL COLLEGE.

The distribution of prizes at the London Hospital Medical College will be made by Lord Rayleigh, D.Sc., F.R.S., on Tuesday, June 24th, at 3 p.m., in the library of the College.

UNIVERSITY OF BIRMINGHAM.

DR. FAUSET WELSH has been appointed assistant lecturer and demonstrator in anatomy, and Dr. C. C. Cookson prosector in the department of anatomy, for the remainder of the current session.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting was held on May 8th, when the President, Lord Moynihan, was in the chair.

Vacancy on Court of Examiners.

The President reported that Mr. Graham Simpson's term of office on the Court of Examiners would expire on June 11th next, and that the vacancy in the Court would be filled at the next meeting of the Council, Mr. Simpson not being a candidate for reappointment.

Portrait of the late Joseph Hodgson.

Dr. L. G. Parsons and Mr. Seymour Barling attended and presented to the College, on behalf of the medical staff of the Birmingham General Hospital, a replica of the portrait by Partridge at the hospital of Joseph Hodgson, President of the Royal College of Surgeons in 1864. The President expressed appreciation of the gift.

Membership.

Diplomas of Membership were granted to the following 138 candidates:

M. Ata Ullah, H. B. Bagshaw, G. N. Bailey, J. E. G. Baker, A. N. Barker, F. Bartholomew, G. R. Bashford, D. A. Beattie, D. H. Bolton, A. E. Bowling, Julia A. Boyd, Mabel Brewster, R. O. Brooks, A. Burkhardt, C. E. Burridge, G. G. Cameron, S. N. Chopra, D. S. Chowdhary, J. F. Coates, A. F. H. Coke, Charlotte A. G. Conway, J. H. Conyers, Margaret E. Cook, H. Coorland, H. D. Cronyn, H. Curtis, A. L. d'Abreu, C. M. Dell, W. J. D'Rosario, P. G. Dowdell, J. C. E. Dusseau, J. J. Eapen, R. E. M. Fawcett, Sheila J. Ferguson, F. H. H. Finlaison, R. H. Fish, E. D. Forster, E. V. Frederick, J. D. J. Freeman, P. R. Graves, S. R. [illegible] C. J. K. Hamilton, D. Hay, Geraldine J [illegible] Heathcote, J. Henry, J. R. Hindm[illegible] Laura M. Hollingworth, S. W. Holmes, Ethel E. Hopper, L. H. Howells, K. N. Irvine, O. Ive, L. A. Jacob, M. M. St.G. Johnstone, E. G. M. Jones, C. Jotikasthira, N. F. Kendall, J. D. Kershaw, S. Lal, F. P. L. Lander, Grace Law, R. H. Leaver, E. Z. Levy, G. S. R. Little, J. B. Lloyd, H. Lwow, H. G. McComas, S. McDonald, W. McKissock, R. W. Malim, Margery L. Maltby, M. Mandelstam, R. S. Mann, C. E. P. Markby, J. H. G. Mason, C. B. Melville, J. B. S. Morgan, F. Murray, F. J. Napier, A. M. Nodine, A. M. Nussbrecher, R. Nutt, C. L. Oakley, G. L. Ormerod, M. Owen, P. M. Oxley, C. H. Pauli, D. D. Payne, M. Phillips, F. E. Pilkington, J. R. F. Popplewell, J. O. Poynton, A. C. Price, S. Ramadas, S. Ramanathan, G. E. Ranawake, J. M. Reese, A. H. T. Robb-Smith, H. E. W. Robertson, C. G. Roberts, M. Victoria Robinson, J. D. Rose, Pattie E. Rose, K. M. Ross, C. A. Rumball, J. Sakula, K. T. Samatapala, L. Seaton, K. M. Seedat, M. H. Shah, Ursula Shelley, Edna F. Sheridan, L. Silman, S. Silman, Phyllis F. L. Simon, J. G. Sleigh, Edith M. P. Smith, P. Somasunder, B. Southwell, G. H. G. Southwell-Sander, T. M. Spilhaus, J. K. Stanger, R. W. Stephenson, B. P. Sur, F. H. Taylor, G. Taylor, J. N. Vasudeva, I. H. Wharton, J. C. G. Whitelaw, D. A. Williams, Rose E. Williams, P. S. Winton, Joyce R. Woods, G. R. H. Wraugham, W. Young.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on May 6th, when the President, Sir Norman Walker, was in the chair.

Drs. James Kirkwood Slater (Edinburgh), John Henry Douglas Webster (London), and Sydney Watson Smith (Bournemouth) were introduced and took their seats as Fellows of the College. Lieut.-Colonel William Frederick Harvey, C.I.E. (Edinburgh), and Dr. Herman Petrus Gunnar (Illinois) were elected Fellows.

Dr. John Orr was elected a representative of the College on the Committee of Management of the Triple Qualification. The Parkin Prize was awarded to Dr. R. J. S. McDowall, F.R.C.P. (London). The award of the Lister Fellowship was divided equally between Drs. Ralph Stockman Begbie and Donald Stewart. Dr. W. A. Alexander, F.R.C.P., was granted recognition as a lecturer on the practice of physic.

The College decided to celebrate the 250th anniversary of its foundation on St. Andrew's Day, 1931.

Intimation was made of a bequest by Mrs. Isabella Kirk Duncanson for the foundation of a Fellowship in Medical Research.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE following candidates have been approved at the examinations indicated:

PRIMARY FELLOWSHIP.—Dr. H. O. Clarke, B. O'Brien.
FINAL FELLOWSHIP.—Dr. R. Grainger, Dr. A. K. M. Khan.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examinations indicated:

FINAL PROFESSIONAL EXAMINATION.—D. Dorgan, V. J. Fielding, T. S. Harbison, J. E. Lewis, J. Lewis, Doris F. Weir.
DIPLOMA IN PSYCHOLOGICAL MEDICINE.—Dr. E. J. Foley.

The Services.

DEATHS IN THE SERVICES.

Major Thomas Henry Hill, C.I.E., Indian Medical Department (ret.), died in London on February 19th, aged 86. His father, also Thomas Henry Hill, served as a midshipman at the battle of Cape St. Vincent in 1797, and subsequently served in Queen Isabella's Lancers during the Portuguese war of succession; then, joining the East India Company's army, he served under Napier in Sind, and in the two Sikh wars. Thomas Henry Hill, jun., was born on February 14th, 1844. In 1849, his mother being dead, and his father being sent to Burma, he entered the Lawrence School for sons of soldiers at Sanawar, near Simla, at the age of 5. When the Mutiny broke out, in 1857, the demand for medical apprentices in the I.S.M.D. was so pressing that he was taken on in that capacity, though only 13 years of age, and served through the Mutiny as a boy. Later on, in 1862, after a course at Calcutta Medical College, he obtained the diploma given to youths who successfully passed their examinations for service in the I.S.M.D. After seventeen years' military duty, chiefly on the frontier, he was posted to headquarters, and employed on the compilation of a code of medical regulations for military hospitals in Bengal, and, after its completion, of a similar code for the whole of India. He was then appointed assistant secretary to the Director of Medical Services in India, and served in that capacity until, after forty-six years' service, including four extensions of a year each, he retired in 1903. He was the first officer of the I.M.D. who was granted the rank of major, and for a long time was the only officer of the Department who held that rank. He received the C.I.E. in 1901. He was, and for several years had been, the last medical survivor of the Mutiny. The last I.M.S. survivor of the Mutiny was Deputy Surgeon-General P. W. Sutherland, a much older man than Hill, who died on May 6th, 1925. In 1890 Major Hill married Ethel, daughter of George Prussia.

Lieut.-Colonel Philip Durrell Pank, Bengal Medical Service (ret.), died in London on March 19th, aged 76. He was born on October 2nd, 1853, the son of Mr. William F. Pank of North Walsham, Norfolk, educated at St. Thomas's, and took the Edinburgh double qualification in 1879. Entering the I.M.S. as surgeon on May 31st, 1880, he became lieutenant-colonel after twenty years' service, was placed on the selected list on October 26th, 1905, and retired on May 17th, 1910. He served in the Mahsud Waziri campaign of 1881, on the North-West frontier of India, and also rejoined for service in the war of 1914–18. Most of his service was passed in political employ in Rajputana. Along with the late Colonel D. ffrench-Mullen, he was the author of *A Medical Topographical Account of Rajputana*, 1900.

Captain Sydney Hartley, M.C., Indian Medical Service, died on February 22nd, aged 35. He was born on March 1st, 1894, and served in the war of 1914–18 as an officer in the Worcestershire Regiment, which he joined as a second lieutenant on September 9th, 1914, becoming lieutenant on February 27th, 1915, resigning on May 12th, 1918. He then studied medicine at St. Thomas's Hospital and Oxford, where he graduated as M.A., M.B., and B.C. in 1922, after taking the M.R.C.S. and L.R.C.P.Lond. in 1921. After qualifying he filled the appointments of house-surgeon, casualty officer, and resident anaesthetist at St. Thomas's, and of assistant medical officer at Lewisham Hospital and Bethnal Green Hospital. He took a commission in the I.M.S. on April 30th, 1925, and was ranked captain from August 28th, 1926. He received the M.C., as a combatant officer, on February 6th, 1918.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Lords has been in committee this week on the Coal Mines Bill. The House of Commons debated the Votes for the Ministry of Agriculture and for the Board of Trade, and also the London Naval Agreement. On May 13th an effort was made to complete consideration of the Mental Treatment Bill, upon which the House sat late. The Canal Boats Bill was reconsidered by the House in committee on May 9th, but consideration was not completed.

Mental Treatment Bill.

The House of Commons, on May 13th, resumed consideration of the Mental Treatment Bill as amended. On Clause 2, which deals with the reception and discharge of voluntary patients, Dr. Fremantle and Dr. Vernon Davies had given notice of an amendment to provide that, if a voluntary patient became incapable of expressing himself as willing or unwilling to continue to receive treatment, he should not be retained as a voluntary patient for a longer period than six months, instead of the period of one month contained in the bill. This amendment was not called by the Deputy Speaker, and on Dr. Fremantle asking if he could not move it, he received the reply that the Speaker had not selected it.

Colonel WEDGWOOD moved the omission of the provision that a voluntary patient who had become incapable of expressing himself as willing or unwilling to continue to receive treatment might be dealt with under the principal Act as a person of unsound mind, or under Section 5 of the bill as a person likely to benefit by temporary treatment. When the bill became law it would be almost inevitable that everybody who went into an asylum would be sent there under the new system, and not under the old. No doctor would be hard-hearted enough to send a patient into an asylum without holding out hope of recovery. He wished to prevent people who went into an institution for voluntary treatment becoming liable to be suddenly converted into temporary patients.

Miss LAWRENCE, in opposing the amendment, said that it was moved under a complete misunderstanding of the position.

Dr VERNON DAVIES opposed the amendment, which he said was unnecessary, and might prove to be dangerous. There was no possibility of a person being illegally detained under the safeguards which existed.

Dr MORRIS-JONES also opposed the amendment. He said that if a person became a danger to himself and those around him there was only one thing to be done. They must act to the best of their knowledge and belief and keep the patient in the institution for his own good. There were the safeguards of two separate medical examinations. The experience of Scotland, where for seventy years there had been no case of illegal detention in a mental hospital, where two-thirds of the patients were voluntary patients, and where there was no judicial intervention of any sort, was evidence that there would be no serious hardship or injustice under this clause.

The amendment was rejected by 241 votes to 106.

Colonel WEDGWOOD moved an amendment to Clause 5, providing that the Board of Control shall, upon the signed request of any person who considers himself to be unjustly detained under an application, recommendation, or order, furnish to him or his authorized representative, free of cost, a copy of such application, recommendation, or order. Mr. GREENWOOD accepted the amendment, which was agreed to. After further discussion (to be more fully reported in the issue of May 24th) the bill was passed through report and read a third time.

Workmen's Compensation (Silicosis) Bill.

The Workmen's Compensation (Silicosis) Bill was considered in committee by the House of Lords on May 7th. Clause 1 proposes to extend the silicosis provisions of the Workmen's Compensation Act (1925) to industries and processes involving exposure to asbestos dust. Viscount BRENTFORD moved to leave out Clause 1 so as to strike asbestosis out of the bill. He said there had been a Home Office report by Dr. Merewether, an inspector of factories, and by an engineering inspector of factories on this subject, and they stated that in 1910–11 an investigation by the Home Office did not disclose evidence of a serious hazard to health in the asbestos industry. Last year 363 workmen who had been longest employed in the industry were examined to find out whether fibroid disease of the lungs from the inhalation of asbestos dust was very serious. The investigators came to the conclusion that 105 out of that number were affected by this form of fibrosis. This was a disease which, so far as was known, had caused only four deaths, and which at present was not within the provisions of the Workmen's Compensation Act. He thought the time had hardly come to put in this new disease. There was not sufficient certainty on the number of deaths or on the incidence of the disease, and no real efforts had yet been made to prevent it. When once a disease was included in the list for workmen's compensation it became more prevalent. When miners' nystagmus was included in the workmen's compensation diseases Parliament was told there would not be more than 200 or 250 cases. There were now 8,000 cases claiming compensation for that disease. Prevention should be tried before compensation was given.

Earl RUSSELL said that Lord Brentford had himself included in the scheme for silicosis many processes which could not show a mortality approaching that for the asbestos industry. In that industry fourteen fatal cases had now been reported. This, after all, was very considerable. There were in addition three deaths from asbestosis associated with tuberculosis. In eight of the seventeen fatal cases the total disablement before death varied from six months to several years, and in four cases from a few days to a few weeks. The incidence rate of this disease was one in eight among those actually employed and at work, or if those employed less than five years were excluded, the incidence rate was one in three. While the fibrosis associated with silicosis was in more or less isolated nodules, asbestos fibrosis was a fine cobweb ultimately permeating the greater portion of the lungs and leaving very little sound tissue. It would not be in the employer's interest to deal with the disease under the ordinary workmen's compensation provisions instead of by the manner proposed in this bill, under which a special medical body was to be set up with a general scheme of medical inspection by people who would be experts, and would be certain whether the disease had occurred or not. Lord Brentford's remark that a disease tended to become more prevalent when admitted for compensation merely meant that previously it had been wrongly diagnosed. Cases which previously would probably have been certified as tuberculosis or pneumonia or an affection of the lungs would now be certified as due to asbestos fibrosis. Earl Russell went on to read a letter in which Lord Askwith, on behalf of the owners of Cornish tin mines, withdrew his opposition to the bill. He said the scheme would be a serious liability upon the Cornish tin industry, particularly as many miners had worked in South Africa and might have the seeds of silicosis, but the mine owners recognized the importance of the measure to their workpeople, and would cordially co-operate in a suitable scheme.

Viscount BRENTFORD asked whether the clause would apply to industries casually using asbestos, such as plumbing. Earl RUSSELL replied that no industry would be subject unless there had been a case of asbestosis, and unless the incidence of asbestosis was real.

After further debate the House agreed to Clause 1.

Clause 2 authorizes the Home Secretary to make a general scheme for all industries, processes, and groups of industries or processes which have silicosis compensation schemes, the purpose of such a general scheme being to co-ordinate the medical arrangements in connexion with these compensation schemes. Such a general scheme may provide for the establishment of a medical expenses fund, and may also secure that employers shall not employ in any process involving exposure to silicosis dust or asbestos dust any workman who has been suspended in pursuance of the scheme, or has refused or wilfully neglected to submit himself to examination under the scheme.

Viscount BRENTFORD moved to omit Clause 2. He said it would involve examination presumably at least once a year of something like 75,000 workmen. When he was Home Secretary he had found that a doctor might be assumed to examine eight hundred cases a year. The clause would require an elaborate system of medical inspection involving about a hundred full-time doctors. A great portion of the expense would fall on employers, who already contributed to the national health insurance system. He assumed that if the bill passed, silicosis cases would be taken out of the hands of the panel doctors.

Earl RUSSELL said the general scheme contemplated in the clause would be confined to medical arrangements and would not deal in any way with compensation. All such questions would, in consultation with the industries concerned, continue to be dealt with by special schemes under Section 47 of the existing Act. Whatever method was adopted for payment of fees into the proposed medical expenses fund the amount that any particular industry would have to bear would depend on the incidence of silicosis in that industry, and not on the number of workers engaged. There was no intention of placing upon every industry under the different silicosis schemes the burden of having all its workers periodically examined irrespective of the incidence of silicosis in the industry. In deciding whether there should be periodic medical examinations one of the governing factors would be the extent to which silicosis was prevalent in the industry. More than one industry not at present subject to this requirement was coming to realize how valuable such examinations were, both to employers and to workers. This disease hardly became definite until after five years' work in the industry, and if its onset could be detected and the man removed from the industry the employer would escape liability to pay compensation. In view of the state of the exchequer, which would be affected by the new arrangement, the Treasury had agreed to make an annual contribution to the medical expenses fund under the scheme. In the refractory and sandstone industries the examinations in the highest

risk occupations were required to be made annually. In others they were required biennially. It was unlikely that the examinations prescribed for any industry or process would be more frequent than once a year, but in the light of experience an even longer period than two years might be allowed in certain occupations. The existing medical board was divided into three panels, with centres at Sheffield, Newcastle, and Bristol, and already covered an area from Devonshire to Caithness and the Orkneys. The new industries which would be brought under the general medical scheme would not greatly extend the area already covered, and it was anticipated that the medical board, with the addition of one or two new panels and centres, would easily cover the whole field. It was the increasing practice of coroners when inquiring into deaths alleged to be due to silicosis to hold the inquiries in co-operation with the medical board. The total cost under the new scheme would rise to between £13,000 and £15,000 a year, an addition of £4,000 or £6,000.

Viscount BRENTFORD said that Lord Russell's reply would give general satisfaction.

The House then agreed to Clause 2, and the bill was reported without amendment. The third reading was set down for May 15th.

Tuberculosis in Cattle.

Mr. SOMERVILLE HASTINGS, speaking on the vote for salaries and expenses of the Ministry of Agriculture, said that the question of tuberculosis in cattle was important for farmers because the cattle most affected were milch cattle. They did not contract the disease in their early years, but when they had reached the milk-producing age. He asked if the Minister could give an accurate estimate of the number of cows so affected. It had been suggested that they numbered nearly 1,000,000, or 40 per cent. of the milch herds of this country. Something between 4 and 8 per cent. of the samples taken of milk exhibited for sale were found to contain tubercle germs. About 2,000 deaths occurred each year among human beings as a result of infection by the bovine bacillus. As far as they knew, the germs reached the human subject in nearly every case by means of milk. Apart from deaths, 20,000 persons were affected by the disease. It was the cause of 46 per cent. of the cases of glandular tuberculosis, 50 per cent. of the cases of lupus, and 66 per cent. of the cases of tuberculous meningitis. It had been suggested that by pasteurizing milk everything necessary was done, but by pasteurizing an impure article they did not make it pure; the toxins and the bacteria were not destroyed. There was also clear evidence that certain changes took place in milk as the result of pasteurization. There was clear evidence that the calcium contained in milk was changed by heating, and became less digestible and less easily absorbed. Experiments showed that children did not do so well on pasteurized milk. From a report issued for 1928 he noticed that something like 1,700 cattle were ordered to be slaughtered; of these, 162 were so bad that they died before there was time to slaughter them. Out of 347 cattle reported as giving tuberculous milk 264 had no lesions of the udder. What was happening under the Tuberculosis Order was merely to destroy cattle after the mischief had already been done. Were the cowsheds in which these animals lived disinfected, and were experiments being carried out by the Ministry with regard to immunization of calves against tuberculosis, or the rearing of stock which was not susceptible to that disease? Farmers in this county had to pay for the T.T. certificates, and also the fees of veterinary surgeons who tested their cows. In Denmark the services of veterinary surgeons and the tuberculin used for testing were given free, and it would be useful if the same thing could be done in this country. Another method might be adopted by the Ministry—namely, that of "accredited" herds. Under that method, which was in use in America, farmers were assisted to have their herds tested, and as soon as "accredited" herds were produced in any number in a district an attempt was made to establish what was known as an "accredited" area. Where 75 per cent. of the farmers wished to form an "accredited" area compulsion was used on the rest, so that the herds might be made free from tuberculosis.

Dr. ADDISON, replying to the debate, said that the position of this country with regard to agricultural research was discreditable. For the last few years we had been spending millions in compensation for animals which had been burned for association with outbreaks of disease. It was only the other day that the country began to spend any substantial amount on research into the cause and prevention of foot-and-mouth disease. It had spent at least £10,000,000 in compensation for animals which were destroyed because they were thought to be infectious. Some years ago, in regard to medical research, the then Government, of which he was a member, got together a committee to exercise a general supervision and to give comprehensive advice on the lines which research might take, the type of cases where research might be undertaken, and so on. The present Government was considering whether it could adapt that kind of method to agricultural research.

Small-pox.—Mr. GREENWOOD said, in reply to Mr. Freeman on May 8th, that he had considered the present method of making periodical returns to the League of Nations Health Committee, under which mild cases of small-pox occurring in this country were compared with severe cases in other European countries, and had requested the British representative to bring to the notice of the League of Nations his suggestion that deaths as well as cases should be reported in order to secure a just comparison with other countries.

Psittacosis.—Replying to Mr. Mander, on May 8th, Mr. GREENWOOD said, in view of the obscure nature of psittacosis, he was advised that no useful purpose would be served by making it compulsorily notifiable. Medical practitioners and others had been invited to report cases to the local medical officer, and this procedure was being followed. The recommendation in favour of notification was merely the expression of an opinion by the compiler of a recent review of psittacosis published in the Monthly Epidemiological Report of the Health Section of the League of Nations.

Caseous Lymphadenitis in Imported Mutton.—On April 23th Miss LAWRENCE told Mr. Thorne that the Ministry of Health had made inquiries into the recent examination for caseous lymphadenitis, at a Wapping cold store, of 541 carcasses of mutton from the Patea district of New Zealand. Twenty-seven carcasses were condemned. Each had attached to the leg a certificate of a veterinary inspector of the New Zealand Government that they had been examined and found sound. The Minister was bringing the matter to the notice of the Government of the exporting country.

Proposed General Medical Service.—Replying to Mr. Freeman, on May 8th, Mr. GREENWOOD stated that he had not yet had an opportunity of considering closely the proposals of the British Medical Association for a general medical service for the nation. These proposals, if adopted, would necessitate legislation.

National Milk Publicity Council.—Replying to Mr. Hurd, on May 1st, Sir C. TREVELYAN said the milk service scheme of the National Milk Publicity Council was in operation in schools in eighty-two areas with the approval and encouragement of local education authorities. Other authorities provided milk meals under their arrangements for provision of meals. He was in close touch with the council to increase consumption of milk in schools. Asked by Mr. SMITHERS what steps were being taken to provide milk free from tuberculosis, Sir C. TREVELYAN said great care was taken in that respect.

Indian Medical Degrees.—Mr. BENN, replying to Major Pole on May 12th, said that he could add nothing to his recent answer with regard to the steps which the Government of India proposed to take following the refusal of the British General Medical Council to extend recognition to Indian medical degrees.

Manufacture of Cocaine in India.—On May 12th Mr. BENN, replying to Mrs. Hamilton, said that recently the Government of India placed before the Indian Legislature a bill to control the traffic of dangerous drugs. One clause of the bill prohibited the cultivation or gathering of the coca plant, and to this clause a select committee added the proviso that the prohibition did not apply to the cultivation or gathering of the plant by Government, the object being to allow Government to grow the coca plant and to experiment in the manufacture of cocaine if at any time it were thought desirable that the cocaine required for proper medicinal uses in India should be produced in India. This appeared to be the foundation of an incorrect report that the Government of India had authorized the cultivation of the coca plant and the manufacture of cocaine. The Dangerous Drugs Act had passed into law, but no action had been taken to authorize the cultivation of coca.

Post-Graduate Facilities for Ship Surgeons.—Mr. W. GRAHAM replying to Mr. W. Thorne, on May 6th, said that he was informed that the British Medical Association were setting up a committee to consider the desirability of providing special post-graduate facilities for ship surgeons. So far as he was aware this would not be concerned with their pay and conditions.

Smoke Abatement.—Replying to Dr. Fremantle, on May 1st, Mr. GREENWOOD said no local authority had made by-laws, or forwarded draft by-laws, under Section 5 of the Public Health (Smoke Abatement) Act, 1926. *Difficulties in framing adequate model by-laws* had not been overcome. Dr. FREMANTLE asked whether, in the opinion of the Ministry, the Act was practically inoperative. Mr. GREENWOOD confessed that might be true.

Pollution of the River Hull.—Mr. BUXTON, replying, on May 5th to Lieut.-Commander Kenworthy, said that he was aware of the serious pollution of the River Hull. He had received no complaint of damage to stock from this cause, nor had the Minister of Health received complaints that the inhabitants of the area affected had been compelled to obtain water from a distance for drinking and domestic purposes. He (Mr. Buxton) had no authority to prevent or control pollution. He had, however, brought the facts regarding the condition of the River Hull to the notice of the local authorities concerned.

Pensions.—On May 12th Mr. F. O. ROBERTS told Dr. Hunter that the cases in which further medical examination in pension claims was requisite were now reduced to very small numbers. Dr. Hunter suggested that present assessments should be made valid for three years and no further medical boards held. Mr. ROBERTS answered that it was the practice of the Department to give prolonged awards wherever justifiable. He had, however, no power to authorize awards which were not covered by medical certificate or to refrain from awarding a permanent settlement in those cases which were suitable for it. Replying further to Dr. Hunter, Mr. Roberts said that legislation to make statutory all awards, whether on errors of final awards or on over seven years' claims, was not necessary or desirable. The mere grant of statutory powers to make awards of the two classes referred to would not in itself confer material rights which pensioners did not already possess. Sir A. POWNALL asked if it were true that only 300 claims beyond the seven years' limit had been accepted, and that 6,000 had been refused. Mr. ROBERTS replied that this was so.

Medical News.

THE eleventh Congress of the French-speaking medical practitioners of North America will be held at the Windsor Hotel, Montreal, from September 16th to 19th, and a very warm invitation is extended to members of the British Medical Association who may be able to participate in it on their way back from the Annual Meeting at Winnipeg in August. The programme includes general sessions devoted to physiotherapy and cholecystitis; clinical programmes in Montreal hospitals; contributions by official delegates from Great Britain, France, and the United States; public health sessions; and various exhibits and entertainments. Further information may be obtained from Dr. Douatien Marien, P.O. Box 58, Station G, Montreal.

THE next reception of the Royal Society of Medicine will be held at 1, Wimpole Street, W.1, on Thursday, May 29th. The President and Lady Dawson will receive the guests at 8.30 p.m., and at 9 p.m. cinematograph films will be shown. Admission will be by ticket only, obtainable from the secretary.

AT the meeting of the Medico-Legal Society to be held at 11, Chandos Street, W.1, on Thursday, May 22nd, at 8.30 p.m., Dr. C. Ainsworth Mitchell will read a paper on forgeries and their detection; a discussion will follow.

THE next meeting of the Biochemical Society will be held in the Department of Physiology, the School of Medicine, Leeds, to-day (Saturday, May 17th), at 3 p.m., when papers will be read and demonstrations given.

A SESSIONAL meeting of the Royal Sanitary Institute will be held in the Public Halls, Blackburn, on Friday, May 30th, when a discussion on the reorganization of Poor Law hospitals under the Local Government Act will be opened by Dr. J. J. Buchan, president of the Society of Medical Officers of Health, at 7 p.m. On Saturday, May 31st, the meeting commences at 10.45 a.m., when a discussion on the need for further legal powers with respect to ice-cream will be opened by Dr. V. T. Thierens.

THE thirty-first annual meeting of the Lebanon Hospital for Mental Disease, Asfuriyeh, near Beirût, Syria, will be held in the Vestry Hall of St. Martin-in-the-Fields, Trafalgar Square, on Friday, May 23rd, at 3.30 p.m., under the chairmanship of Dr. Bedford Pierce, one of H.M. Commissioners in Lunacy. The speakers will include Dr. F. H. Edwards, late medical superintendent of Camberwell House.

CONTRIBUTORS to the George Vivian Poore Memorial Fund and all interested in the homecroft movement are invited to the annual general meeting of the National Homecroft Association to be held in No. 2 Committee Room, Church House, Dean's Yard, Westminster, on Thursday, May 22nd, at 3.45 p.m.

THE annual meeting of the German Opthalmological Society will be held at Heidelberg from June 12th to 14th, and of the German Central Committee for the Investigation and Control of Cancer, at Dresden at the same date.

DR. L. S. BURRELL will deliver two lectures in the M.R.C.P. evening course arranged by the Fellowship of Medicine, on May 20th and 23rd, in the lecture hall of the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1, at 8.30 p.m.; the subject of the first will be intrathoracic tumours, and of the second, bronchiectasis and abscess of lung. On May 21st, at 11 a.m., Mr. Rugg-Gunn will give a clinical demonstration at the Western Ophthalmic Hospital, *Marylebone* Road, and on May 23rd, at 2 p.m., Dr. Yealland will demonstrate at the Prince of Wales's Hospital, Tottenham. No fee is payable for either of these two demonstrations. For those interested in diseases of the heart and lungs there is one week remaining of the special course at the Victoria Park Hospital; the whole of each day can be spent at the hospital, and instruction will include special demonstrations in the various departments of the hospital. The Central London Ophthalmic Hospital will hold a four weeks' course from May 19th, consisting of instruction by operation, demonstrations, and special lectures. A comprehensive morning course will be undertaken by the staff of the Hospital for Sick Children from May 26th to June 7th; early entry is desirable, as the course will only be held if there is a minimum entry of twelve. From May 26th to June 7th a course will be held at Queen Mary's Hospital, Stratford; the daily sessions, which begin at 10.30 a.m. and finish at 5.30 p.m., will comprise instruction in medicine, surgery, and the specialties, with special reference to tuberculosis. The subjects of courses to be held in June are: gynaecology, dermatology, proctology, and another intensive course in medicine, surgery, and the specialties. Copies of all syllabuses, and information relating to post-graduate work are obtainable from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A SERIES of eight lectures on tropical hygiene for lay persons proceeding to the Tropics will be given by Lieut.-Colonel G. E. F. Stammers, R.A.M.C. (ret.), from May 28th to June 6th (with the exception of May 31st and June 1st), at the London School of Hygiene and Tropical Medicine, at 5.30 p.m. The subjects include: acclimatization; choice of suitable dietary; the designing and equipping of houses; sanitation of camps; and the etiology and prevention of various tropical infections. Full particulars can be obtained from the secretary of the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1.

A SCHEME has been issued by the Ministry of Health under Section 102 (2) of the Local Government Act, 1929, giving particulars of the annual contributions to be paid from April 1st, 1930, to March 31st, 1933, by councils or combinations of councils of counties and county boroughs to voluntary associations providing assistance or supervision for mental defectives who are outside the care of institutions. Councils are authorized to require the observance of conditions relating to the efficiency, alteration, inspection, and financial supervision of the service provided, but the consent of the Minister of Health must be obtained before any contribution may be reduced or terminated. These conditions also apply to the payment of annual contributions made to the Central Association for Mental Welfare, whose services are under the supervision of the Minister. Disputes and differences arising between councils and associations are required to be referred to the Minister, whose decision is final and binding. Local authorities are informed in a circular letter that their contributions to voluntary associations may exceed those set forth in the schedules.

AT a meeting of the Society of Public Analysts on May 7th Mr. D. R. Wood, F.I.C., discussed the examination of milk for tubercle bacilli. A survey was given of the experience and results obtained in the examination of 1,000 herds in Somerset during the last four years. The relative value of microscopical and biological tests was considered, and experiments on the cytology of tuberculous milk were described. The limitations of veterinary inspection were pointed out, and the conclusion was drawn that the present methods were inadequate for the elimination of tuberculous milk.

THE Metropolitan Water Board adopted, at its meeting on May 9th, the recommendation of the Water Examination Committee that the services of Sir Alexander Houston, Director of Water Examination, who is due to retire, should be retained.

IN the seventeenth annual report of St. Andrews Hospital, Dollis Hill, N.W., an appeal is made for assistance towards the opening of a children's ward and the establishment of an electrical department. During 1929 245 children received treatment. Funds are also required for the payment of new wards and a nurses' home in course of erection. Since the issue of the last report a new ward pavilion, consisting of two wards of twelve beds each and an operating theatre, has been opened, and permanent beds have increased from 52 to 74. Although there is no out-patients' department, it was necessary to deal with 272 accident and other urgent cases during the year. The hospital makes no distinction of nationality or creed, and many patients are admitted who cannot afford to contribute anything towards their maintenance.

WE have received a copy of the publications of the Ravetllat-Pla Institute of Barcelona containing essays by Dr. Pla y Armengol and others on the results of inoculation of the tuberculous virus into newborn animals; filtration of *the tubercle virus; the rapidity of dissemination* of the tubercle virus in the organism; the biology of the virus of tuberculosis; the etiology of tuberculosis; and the study of B.C.G.

THE International Labour Office has issued from 12, Victoria Street, S.W.1, eleven further brochures, Nos. 184 to 194, in its series "Occupation and Health," the subjects dealt with being dinitrophenol; dinitrobenzene; ether; fatigue tests; fertilizers and manures; glass industry; graphite; hides and skins; iron, pig iron, and steel industries; iron carbonyl; ice-cream makers; and lignite.

LIST No. 103 of the Cambridge Instrument Company, Ltd. (45, Grosvenor Place, London, S.W.1), contains descriptions of Cambridge instruments for measuring hydrogen-ion concentration, and an account of the applications of hydrogen-ion measurements in research and industry.

ON the occasion of the celebration of the centenary of the independence of Uruguay, a medical congress, consisting of fourteen sections, will be held at Montevideo from October 5th to 12th, under the presidency of Dr. Luis Morquio, professor of children's diseases at Montevideo.

DR. HENRY SALOMON (Leicester) has been awarded the Government grant for the third time for successful vaccination in his district.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

CHRONIC MYELOGENOUS LEUKAEMIA.

"PUZZLED" inquires if there are any new theories on the etiology or treatment of the above condition. The patient is a young [illegible] references (British or foreign) would be [illegible]. Radium and deep *x*-ray therapy have been tried.

TATTOOING AND PROPHYLAXIS.

DR. ROSE JORDAN (Catford) writes: A man, aged 25, recently presented himself for examination at the tuberculosis dispensary as a contact of his brother, who had contracted pulmonary tuberculosis. He was in excellent health, muscular, and in good condition. He had served eight years in the army and had spent seven of them in India. Both his arms were elaborately tattooed in red and blue. One of the reasons he gave for having submitted himself to this decorative art was that it gave protection against infectious diseases. He told me that soldiers with well-tattooed bodies *rarely* went sick. *Is* this merely a superstition, or does the impregnation of the skin by these dyes really afford any protection against tropical diseases?

FLEA INFESTATION.

DR. B. F. FALKNER writes: "Pulex" (May 10th, p. 892) should try a vigorous spraying of all cracks, fissures, and corners of rooms with formalin. I had the same trouble some years ago when I went to live in an old house in a rural district of Kent. I had a very terrible fortnight, as the fleas were in battalions and of a huge size. Spraying with "Flit" is also a good remedy.

INCOME TAX.

Assessment of War Loan Interest.

"S. B." acquired some War Loan in September, 1929, receiving £*x* interest on December 1st, 1929. What is his liability to assessment for the years to April 5th, 1929, and April 5th, 1930, respectively?

*** Interest is assessable on the basis of the actual year for the first and second financial years for which the income is received, and thereafter on the basis of the previous year. "S. B." is therefore liable to be assessed on £*x* for 1929-30 and 2×£*x* for 1930-31.

Assistant becoming a Partner.

"J. C. H." entered into partnership on April 1st, 1930, having previously been engaged as an assistant. Is it to his financial advantage for the partnership to be treated as a new business for 1930-31?

*** The answer clearly depends on whether the profits as computed for income tax purposes for 1930-31 will be less than for 1929-30. Obviously many causes must operate in such circumstances, and it is a matter of difficulty to estimate what the net result will be; but if the practice was paying an assistant in 1929-30 and, by reason of "J. C. H." having become a partner, will not do so for 1930-31, that of itself will have a tendency to increase the assessable profits for 1930-31, and to that extent to render it unwise to claim the cessation and recommencement method. In addition, it normally involves a departure, at any rate for a time, from the convenient cash basis method.

Cost of Special Courses.

"T. S. D." has been holding various senior hospital posts, and during that time has expended money for special tuition, examination fees, etc. This was expected of him by the hospital authorities, but was not a definite condition of his employment. Can he deduct these expenses for income tax purposes?

*** No; they cannot be brought within the rule that the expenses must be incurred "wholly, exclusively, and necessarily in the performance of the duties of the office." There is the further objection that as they were incurred to increase "T. S. D.'s" professional knowledge for use over a tract of future time they are in the nature of capital outlay.

Cost of Professional Books.

"B. M. T." inquires whether he can claim the cost of a reasonable number of new medical books each year, or whether they must be definite replacements of old editions of the same book.

*** In our opinion the medical reference library of a general practitioner can be regarded as a whole, and the expense of maintaining it in a reasonably up-to-date condition can be claimed without regard to the individual books replaced. [With regard to the expense of a post-graduate course, please see reply to "T. S. D." above; the expense is not allowable for income tax purposes.]

LETTERS, NOTES, ETC.

BOOKS AND MAGAZINES FOR HOSPITALS.

IN 1919 the British Red Cross Society and the Order of St. John reorganized the then existing War Library for the Sick and Wounded on a peace-time basis. Books, magazines, and periodicals are collected from the general public and supplied by the united societies to a large number of hospitals and sanatoriums. The tenth annual report of the library committee of the two societies covers the twelve months ending September 30th, 1929, during which over 120,000 books and the same number of magazines and papers were distributed to 1,600 hospitals and other institutions. The first care of the hospital library is to collect books for ex-service men undergoing treatment. Gifts of money have also been received enabling the committee to buy many books specially asked for by patients, and to obtain children's books, for which the demand outruns the supply. An appeal is made particularly for monthly magazines, of which an inadequate number is being received, though they are among the most popular and necessary gifts for patients. Parcels should be addressed to the secretary, the British Red Cross Society and Order of St. John Hospital Library, 48, Queen's Gardens, Lancaster Gate, W.2. Leaflets for distribution describing the aims and work of the library are also obtainable on application to the secretary.

SHANTUNG MEDICAL SCHOOL.

THE annual report of the School of Medicine of Shantung Christian University for the year ending June 30th, 1929, has been received. This University is governed by a joint administration consisting of American and British sections. Its work was interrupted by military disturbances during the spring of 1928; the autumn term commenced, however, at the end of the following August, and, although Tsinan was still occupied by Japanese troops, there was no further interruption. Since 1915, 220 medical students have graduated at the University, and of these at least 197 are in active practice, most of them having served first in mission hospitals, and about half being engaged in private practice or in the service of the Government. The report contains other *details of the useful work being carried on in this* part of China in introducing Western medicine and equipping institutions.

X-RAY VIEWING LANTERN.

PHILIPS LAMPS LIMITED (145, Charing Cross Road, W.C.) send us a pamphlet describing their viewing lantern for radiographs. The lantern is constructed of sheet metal, and arranged to take all film sizes up to 12×15 in. With the object of getting a perfectly even illumination, whiter than ordinary electric light, the lighting is effected by two 60-watt "daylight blue" lamps, arranged to provide indirect lighting in such a way as to show every detail that is on the film. The lantern is furnished with rubber feet, and means are provided for securing it readily to a wall in either a vertical or a horizontal position.

EPHEDRINE.

MESSRS. BAILLIÈRE, TINDALL AND COX, 8, Henrietta Street, W.C.2, inform us that they are the publishers in this country of Chen and Schmidt's monograph entitled *Ephedrine and Related Substances*, which was mentioned in the annotation on this drug in the *Journal* of May 10th (p. 873). The book will shortly be available.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 50, 51, 54, 55, and 56 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 53.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 227.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

446. Cardiac Neurosis.

W. D. REID (*New England Journ. Med.*, February 6th, 1930, p. 264) defines cardiac neurosis as a form of effort syndrome which is related more to psychical than to physical activity. Patients suffering from this psychoneurosis form a large and well-defined group, since they are not easily managed in practice; and because the condition is generally ill understood there is a tendency for them to receive indifferent treatment. Diagnosis is usually simple, and depends upon the exclusion of organic disease, both in the heart and elsewhere in the body. It must be remembered that cardiac neurosis may exist in conjunction with organic heart disease. The importance of a routine examination is emphasized; it is sometimes necessary to procure concrete evidence by an *x*-ray film or the electro-cardiograph in order to convince the patient that he has no organic disease of the heart. Elucidation of the cause of the neurosis may not be easy, and it is often necessary to recall the periods, phases, and accidents of life that are apt to produce psychical disturbances. Some of these factors are weakness of constitution, solitary childhood, restless or excitable parents or teachers, the emotional reactions of adolescence, business worries, and the many conflicts and stresses of life. The principles of therapy fall into four main groups: (1) suggestion, (2) persuasion, (3) analysis, and (4) re-education. In some patients the relief obtained from negative findings on examination is sufficient to produce immediate and definite benefit. In other instances it is necessary to discuss the elements of cardiological diagnosis, and to emphasize the absence of physical signs in the individual examined. A few patients require careful analysis before the psychoneurosis can be cured, and not infrequently in severe cases repeated interviews are needed before the patient is re-educated and acquires a new and healthy philosophy of life.

447. Angina Pectoris and Adrenaline.

S. A. LEVINE, A. C. ERNSTENE, and B. M. JACOBSON (*Arch. Int. Med.*, February, 1930, p. 191) studied the electrocardiographic changes in normal persons and in those suffering from angina pectoris following subcutaneous injections of adrenaline. Previous experience had shown that anginal subjects developed typical attacks after such injections, and the authors investigated the possibility of this effect having a diagnostic value in doubtful cases. The drug was administered in 1 c.cm. doses to three groups of persons: one group of 11 with angina pectoris, one of 10 of the same average age without angina, and another of 10 normal young adults. Typical pain resulted in all but one of the patients with angina, while no pain occurred in any of the controls. In the anginal group the T wave increased slightly in amplitude, but in the other two groups it showed a tendency to decrease; the increase in blood pressure and pulse rate was slightly greater in the anginal group than in the others. Because of the regularity with which adrenaline produces pain in patients with undoubted angina pectoris, its therapeutic use, and also that of ephedrine, is contraindicated; it may, however, serve a useful diagnostic purpose in those doubtful cases in which other possible explanations for the pain, such as gall-stones, or gastric or duodenal affections, are present, and in which information as to the presence or absence of angina is essential. Nearly all the patients showed the characteristic effects of adrenaline—namely, tremor, palpitation, sweating, pallor, flushing, nervousness, weakness, and pulsations in the neck and epigastrium; these manifestations were usually only of moderate severity, and none of the anginal patients gave the marked reactions which occur in persons sensitive to the drug.

448. Tuberculosis Mortality in Denmark.

K. FABER (*Nordisk Medicinsk Tidskrift*, February 22nd, 1930, p. 113) states that Denmark, with a population of about three and a half millions, has sixteen sanatoriums with 1,393 beds, thirty-six tuberculosis hospitals with 1,033 beds, three coast hospitals with 428 beds, eleven coast sanatoriums with 571 beds, and four nursing homes with 132 beds—a total of seventy institutions with 3,607 beds. This means that there are 131 beds available for every 100 deaths a year from tuberculosis, or more than one bed for every 1,000 inhabitants. Anyone can receive free treatment at these institutions without suffering from the stamp of pauperism, the State paying three-quarters and the local authorities paying one-quarter of the cost of running them. The fact that a high proportion of patients suffering from tuberculosis die in these institutions, instead of at home, is of considerable importance in limiting the spread of infection. In Copenhagen, for example, 75 per cent. of all the tuberculosis deaths occur in institutions for the tuberculous; and outside [illegible] from 25 to 50 per cent. [illegible] the tuberculosis death rate [illegible] aid is provided, 63 per cent. of the population over the age of 15 belonging to friendly societies whose members receive free medical treatment. Both they and their children are also admitted to hospital without charge. One of the many tables published by the author shows the decline of the tuberculosis death rate, classified according to age, sex, and locality, during thirty years—that is, from the period 1890–94 to the period 1920–25. The greatest decline occurred in childhood, ranging from 70 to 80 per cent., and being approximately equal for the two sexes. But in adolescence and early adult life this decline was much less marked; in Copenhagen among males between the ages of 15 and 19 it was only 47.5 per cent.; in the following age group, 20–24, in males in Copenhagen, this decline was further reduced to 37.9 per cent. The corresponding figures for females in these two age groups in Copenhagen were still less satisfactory, and it would seem that the tuberculosis death rate among women between the ages of 15 and 24 has been almost stationary during the past thirty years, the decline being only 4.1 per cent. in the age group 15–19, and only 8.4 per cent. in the age group 20–24. After the age of 25 the decline in the tuberculosis death rate again became much more marked, and in the age group 55–64 there was a decline of 72.6 per cent. among males in Copenhagen. After showing how the decline in the tuberculosis death rate varies greatly with the age, sex, and place of residence (town or country) of the patient, the author concludes that the campaign against tuberculosis as a directly infectious disease has been most effective in the three following groups: (1) in early childhood, in both sexes, in town as well as in country districts; (2) in adult life, among males living in towns; (3) in adult life, among females living in the country. He explains these differences in sex, age, and locality in terms of facilities for infection and reinfection; but he admits that he cannot distinguish numerically between the parts played by first infections and super-infections respectively.

449. Mumps Complicated by Meningo-encephalitis.

E. E. ZEMEK (*Minnesota Med.*, February, 1930, p. 107) records three personal cases, in males aged 11, 17, and 36 respectively. In the first case there was no definite history of mumps, but an epidemic existed and there was a history of probable contact. The symptoms were frontal headache, fever, vomiting, hyper-irritability, and general malaise. Rapid recovery followed lumbar puncture. In the second case, on the other hand, there was definite parotid involvement followed by delirium and amnesia, which cleared up promptly after spinal puncture. In the third case there was a history of mumps in the family, and orchitis coexisted with meningeal symptoms, which yielded at once to spinal puncture.

Surgery.

450. Combined Radiation Treatment of Malignant Growths.

H. BERNHARDT (*Med. Klinik*, January 17th, 1930, p. 83) recommends isaminblue, either alone or as a preparation to radiation, in advanced carcinomata; he reports 200 cases so treated. Isaminblue is a sulphonized compound of tri-beta-naphthol and pararosaniline; intravenous injections are given of a 0.75 to 0.8 per cent. aqueous solution, or a 5 per cent. solution in glucose. With fresh solutions there is usually no disturbance, but if the temperature rises further treatment must be delayed; sometimes definite sensations are felt in the tumour area. The dye is stored by the whole body, but the connective tissue round the tumour and metastases and the affected lymph vessels seem to have a special affinity for it, their resisting powers being enhanced. In cases unsuitable for radiation 2 to 2.5 grams are given; when used as a preliminary to irradiation 1 to 1.2 grams are given in twelve to fifteen injections spread over two to three weeks. The author states that after five to seven injections definite signs of improvement are found, including an arrest of the loss of weight, improvement in the anaemia, return of the basal metabolism and cholesterin figures towards the normal, better general health, and alleviation of the pain. During

the treatment increased carbohydrates are necessary in the food, calcium is administered, diathermy of the tumour and metastases may be employed, and opiates are stopped or lessened. The treatment lasts for about a month and is repeated in a modified form three to four months later; in some cases the effect is not manifest until some weeks after. The author considers that in a relatively high percentage of cases this drug hinders and even arrests malignant growth, preparing the tissues for irradiation and enabling advanced cases to be modified favourably for exposure to x rays.

451. Sarcoma of the Lung.

S. P. FEDOROFF (*Zentralbl. f. Chir.*, March 22nd, 1930, p. 707), who records an illustrative case, states that formerly primary malignant tumours of the lung were regarded as rare, as is shown by the fact that at Basle carcinoma of the lung formed only 1.76 per cent. of all carcinomas, and at Breslau only 1.85 per cent. In recent years, however, malignant disease of the lung has been diagnosed more frequently during life or found at necropsy. The statistics of [illegible] Pawydowsky and Alexejeff, for instance, [illegible] the period 1923–28, among 37,849 necropsies performed at Moscow, 2,788 cancerous affections were found. Of these, 64.7 per cent. involved the alimentary canal, and 12.04 per cent. the female sexual organs, while 12.04 per cent. were cases of primary cancer of the lung. Primary cancer of the lung, therefore, would appear to be as frequent as cancer of the female genitals, but it must be taken into consideration that a number of women are cured by operation or radium, and therefore do not come to necropsy. The course of pulmonary cancer varies. Sometimes it is very slow and is not infrequently mistaken for tuberculosis, while in other cases it is very rapid. Cases have recently been described in which carcinoma or sarcoma of the lung has been removed, the tumours being separated from the lung by a capsule. In one instance (Divis and Sikl) the patient was in good health a year after the operation. Fedoroff's patient was a woman, aged 38, in whom the symptoms had lasted nine months before operation, and had been mistaken first for those of hydatid disease and later for a dermoid cyst of the lung. An encapsuled tumour was found in the right lower lobe and was removed. Death from haemorrhage took place twelve days after the operation. Microscopically the tumour proved to be a mixed-celled sarcoma.

452. Injection Treatment of Varicose Veins.

E. J. GARVIN (*Med. Journ. and Record*, March 5th, 1930, p. 247) recommends the use of a solution composed of equal parts of 20 per cent. sodium chloride and 50 per cent. dextrose. This combination is less irritating than 20 per cent. sodium chloride alone, and it does not cause sloughing if injected accidentally into the adjacent tissues. The area to be injected is blocked off with a proximal and a distal tourniquet. The skin is cleansed with tincture of green soap, followed by alcohol. With the patient in the standing position, the needle is inserted into the vein; the patient is then allowed to sit, the foot being raised on a stool. The proximal tourniquet is removed to lessen the congestion, and is reapplied. From 2 to 10 c.cm. of the solution is injected through a small bore needle, the most distal varix being injected first. Immediately after the injection a pressure bandage is placed over the site. The tourniquets are allowed to remain on for three to five minutes following the injection. The treatment is given every other day; five or six injections were found necessary in the cases reported. Pain may appear at the site of injection: it gradually lessens, and finally disappears after forty-eight hours. Contraindications are: obstruction of the deep veins of the leg; phlebitis or history of a recent attack; and severe cardiac lesions.

453. Ischio-rectal Prostatectomy.

J. MINTON MEHERIN (*Arch. of Surg.*, March, 1930, p. 437) points out the disadvantages in the removal of the prostate gland by the suprapubic and perineal routes owing to the difficulties in haemostasis and after-care of the wound in the first case, and the inadequate exposure obtained by the perineal method. He claims that ischio-rectal prostatectomy is more satisfactory, and commends the Voelcker method of operation. One advantage of this procedure is that it proceeds under observation of the eye, and therefore it is not likely that pieces of adenoma will be left behind. Moreover, exact haemostasis by ligature, suture, and packing is possible, and good drainage from the base of the wound is assured. Post-operative epididymitis can be controlled by the performance of vasotomy before treatment with the indwelling catheter is commenced. A review is given of 148 cases of prostatectomy by this method, eight surgeons being concerned; the mortality rate was 4.07 per cent. There were no deaths from operative shock, and permanent fistulas or incontinence have not occurred as a post-operative complication.

Therapeutics.

454. Treatment of Chorea.

G. MARINESCO, O. SAGER, and G.-T. DINISCHIOTU (*Ann. de Méd.*, March, 1930, p. 237) strongly advocate the use of luminal and magnesium sulphate in the treatment of both acute and chronic chorea. If luminal be employed, 0.22 eg. of the sodium salt should be injected subcutaneously twice a day for twenty to twenty-five days. Magnesium sulphate should be given intraspinally in doses of 0.008 mg. per kilo of body weight in a freshly saturated (25 per cent.) solution; these injections should be repeated every five to six days. Disadvantages in the employment of the latter drug are the necessity for perfect sterilization of the solution and the difficulty of performing lumbar puncture owing to the agitated state of the patients; moreover, transient paraparesis and retention of urine may occur. No ill effects have been noted after the administration of luminal. Five cases of chorea, illustrative of the beneficial effects of these medicaments, are reported; four were treated with luminal and one with magnesium sulphate. The physiological pathology of chorea is discussed, and various authorities are cited. The present authors emphasize the great importance of the proprioceptive afferent system in the execution of normal movements, and also its importance in a pathological state in the production of the choreic syndrome, which can be caused either by absence of transcortical or diencephalic inhibition, or by a block of the afferent system. Kinnier Wilson and Foerster attach great importance to the dentato-rubro-thalamic system as the agent of this inhibition. The present authors consider that a humoral inhibition is also a great factor, and cite the well-known inhibitory action of calcium ions in the diencephalon, and the important part played by the endocrine glands and the sympathetic system in the mechanism of inhibition. The emotional instability of choreic patients (facile laughter and weeping, irritability, etc.) points to sympathetic and humoral disturbances. The abolition or diminution of the tendon reflexes in chorea is due to a functional trouble of the upper proprioceptive reflex arcs which normally intervene in the reflex functioning of the cord. Luminal and magnesium sulphate cause a diencephalo-mesencephalic inhibition which compensates for the normal inhibition of the striate body on the pallidum, and also produces a block between the proprioceptive and extrapyramidal passages, thus preventing afferent impulses from following an abnormal extrapyramidal route. By inhibition of the thalamus impulses are prevented from reaching the cortex in great numbers, and this permits of a better transcortical inhibition. The curative effect of luminal and magnesium sulphate is due to the action of the former on the cerebral circulation and cellular permeability, and of the latter drug on cellular permeability.

455. Autogenous Vaccine Therapy in Meningococcal Meningitis.

E. APPELBAUM (*Arch. of Pediat.*, January, 1930, p. 61), who records an illustrative case, states that though the use of vaccines in the treatment of meningococcal meningitis has been described by a number of authors, they have been used mostly in conjunction with other forms of therapy and in the subacute or chronic stage of the disease when serum seems to have become inefficient. Very few favourable reports have been made of the use of vaccine in the acute stage. Appelbaum's patient was a female infant, aged 20 months, in whom vaccine was used early in the course of the disease, as seventy-two hours after the second dose of serum a high degree of sensitivity developed and a most violent reaction resulted. Vaccine therapy was continued for about a month in progressively increasing doses. Subcutaneous injections were given every day and intraspinal injections every other day. The maximum subcutaneous dose was 500 million bacteria and the maximum intravenous dose one billion. On several occasions only a few cubic centimetres or no fluid at all could be obtained on lumbar puncture, indicating the presence of adhesions or partial block. Finally complete recovery ensued apart from loss of the right eye due to panophthalmia.

456. Treatment of Lymphangitis, Phlebitis, and Erysipelas.

S. KRÜGER (*Med. Welt*, March 15th, 1930, p. 367) for many years has had excellent results in the treatment of lymphangitis, phlebitis, and erysipelas by application of a dressing containing 50 parts of alcohol 96 per cent., and 1 part of sublimate solution 1 per 1,000. In cases where the skin could not tolerate sublimate a solution of copper sulphate (1 to 1.5 per cent.) was substituted. Within twenty-four hours after commencing the treatment the process was checked, and the swelling subsided in another twenty-four hours. The copper sulphate and alcohol application also proved useful in long-standing cases of whitlow and prevented the necessity of removing the nail.

Anaesthetics.

457. Infiltration Anaesthesia in Fractures.

C. O. RICE (*Anesthesia and Analgesia*, March–April, 1930, p. 76), from an experience in over 200 cases, advocates the employment of infiltration anaesthesia whenever muscular relaxation is necessary for the manipulative reduction of simple fractures and dislocations. Infiltration into the fracture gap is usually all that is required to obtain local analgesia and relaxation if reduction is undertaken at once, but after the lapse of a day or two infiltration of painful points and the surrounding tissues may be needed. After sterilizing the skin over the fracture with iodine, 5 to 10 c.cm. of a 1 *per cent. procaine-adrenaline* solution is injected into the fracture gap, and if anaesthesia and relaxation are not developing within three or four minutes the periosteum of the proximal fragment is then infiltrated around its entire circumference. By slowly infiltrating ahead of the needle the pain attending the process is minimized, and anaesthesia and relaxation are complete within ten minutes. Certain points of entrance are suggested for each type of fracture or dislocation in order to decrease the risk of injuring nerves and blood vessels. Although theoretically a compound fracture is produced the danger under ordinary precautions is negligible, and the procedure may be regarded as simple and safe, and not interfering with union; it is also of use should further manipulation of the fragments be required. By its means satisfactory alignment is made easier because the patient can be taken to the *x*-ray room and the fragments adjusted under direct vision. In a child of 3 with fracture of the forearm the method answered admirably, and the author adds that his successor has reported its satisfactory employment in more than 500 fractures.

458. Spinal Anaesthesia.

S. J. STABINS and J. J. MORTON (*Annals of Surgery*, February, 1930, p. 242) record 100 cases in which Pitkin's method of spinal anaesthesia was used, 2 c.cm. of spinocain being injected for operations below the umbilicus and 3 c.cm. for operations above it. A *hypodermic injection of ephedrine* sulphate 0.05 gram was given fifteen minutes before the spinal anaesthesia. The lateral prone position proved to be the best for injecting the spinocain, the patient being lowered into the Trendelenburg position immediately afterwards to prevent too great early diffusion and to assist the cerebral circulation. It was clear that a most careful technique was required to secure ideal anaesthesia at the desired level, and supplementary inhalation anaesthesia was sometimes necessary for long operations. Morphine or scopolamine is recommended before the spinal anaesthesia. It was found that there was no greater freedom from pulmonary complications than in any other form of anaesthesia, but post-operative discomforts, such as nausea, vomiting, gas pains, and distension, were considerably less. Spinal anaesthesia gives perfect relaxation of the abdominal wall and consequent ease of exposure. The stomach and intestines undergo violent peristalsis and spasm, so that the bowel remains small and contracted, and does not interfere with the operation. Spinal anaesthesia is to be commended in gall-bladder and pelvic operations, in non-inflammatory conditions of the stomach and intestines, in early intestinal obstruction, and in obese patients with ventral hernias. It is also held to be an ideal form of anaesthesia for cases of diabetes when not associated with marked hypertension, since there is no disturbance in the routine treatment or of the kidneys and general metabolism. It should also be used for major surgery of the extremities and for abdominal surgery in the presence of pulmonary tuberculosis. It was found that in some cases spinal anaesthesia was useful for paralytic ileus not associated with infection or mechanical obstruction. Contraindications are marked sepsis, perforations of viscera, peritonitis or localized intra-abdominal abscess, general cachectic states, hypotension, marked hypertension, and paralytic ileus associated with peritonitis. It is considered that the induction of spinal anaesthesia is not devoid of the risk of serious consequences, and that therefore it should only be employed when there is a real indication for it.

459. A. S. JACKSON (*ibid.*, p. 256) concludes that spinal anaesthesia, when properly induced, is the safest from the standpoint of the patient and the most convenient for the surgeon. A series of 1,000 cases is reviewed; there were no fatalities traceable to the spinal anaesthesia, and it is now being used as a routine procedure in all major operations below the diaphragm, as well as in some minor procedures such as cystoscopy. In cases of operations on the gall-bladder or on gangrenous and ruptured appendices, convalescence was largely devoid of the shock which would have resulted from inhalation anaesthesia; spinal anaesthesia was used in one case of perforated duodenal ulcer in a middle-aged man who was suffering from profound shock and severe peritoneal pain, with immediate relief. Post-operative sequels, such as pneumonia, embolism, ileus, gastric dilatation, and cardio-renal vascular complications, are materially reduced by the use of spinal anaesthesia; the technical difficulties of operating are simplified, particularly in cases of acute intestinal obstruction, since there is such relaxation of the peritoneum and other structures that the operative area is enlarged and the closure of the wound is facilitated. The prophylactic administration of ephedrine to govern the blood pressure has made spinal anaesthesia more popular. The technique used by the present authors was that worked out by Stout. It is admitted that there is great danger if care is not taken as regards technique, but when the correct method of induction is followed spinal anaesthesia is held to be absolutely safe.

460. Premedication for Local Anaesthesia.

G. DETAKATS (*Surg., Gynecol. and Obstet.*, February, 1930, p. 494) reports an experimental investigation aimed at the establishment of a method of producing a state of somnolence in patients under local anaesthesia; in a series of 35 patients he tested the relative values of intravenous, subcutaneous, and oral administrations of various hypnotics of the barbituric acid series. Ten patients were injected intravenously with 2 c.cm. of a 20 per cent. somnifen solution; a definite effect was produced without any untoward symptoms, but its duration was too short. In a second series from 20 to 60 cg. of neonal was injected intravenously, and in a third series 2 c.cm. of a 15 per cent. solution was injected subcutaneously; in a fourth series 20 cg. doses of neonal or allonal were given by the mouth three times during the day before the operation and at night, the total amount so administered being one gram of neonal in the twenty-four hours. The advantage of inducing rapid deep anaesthesia by intravenous medication is offset, in the author's opinion, by the uncertainty of action, the prolonged sleep, and the inability to counteract its effect. DeTakats thinks that the intravenous injection of one of the barbituric acid series seems to be indicated in poisoning with cocaine and its derivatives, since they have protective action. He believes that deep anaesthesia could be induced with larger doses, but after a trial in 35 cases the attempt was abandoned as being unsuccessful because of the considerable individual variations.

Obstetrics and Gynaecology.

461. The Terminology of Cervical Erosion.

K. V. BAILEY (*Surg., Gynecol. and Obstet.*, March, 1930, p. 513) reports the results of examining histologically 850 specimens of the uterine cervix with a view to determining the precise pathology of so-called cervical erosion, and, with this as a basis, to inquire into the problem of the inception of cervical cancer. He maintains that the group of cases hitherto known as proliferative erosion would be more accurately described as "peri-oricular cervicitis"; infection limited to the glandular cells is properly termed "glandular cervicitis"; and a third group of ulcerative erosion receives the name "ulcerative cervicitis." The features of this last group are: (1) a depressed granulomatous area extending deeply into the subjacent tissues, presenting a relatively dense structure, and containing no epithelial structures; and (2) the presence of a highly irritative type of adjacent squamous epithelium, due to ineffective proliferative downgrowths from the basal layers. Bailey remarks that erosion is divisible into stages depending on the length of time during which the local inflammatory stimulus and the reaction to it continue, and he gives illustrations of the histological diagnostic criteria in each case, emphasizing the importance of this variety of examination in determining the exact nature of such conditions of the cervix. These earlier manifestations are, he adds, of particular importance in view of the ultimate sequel to erosion—namely, malignancy.

462. Bacilluria during Pregnancy and the Puerperium.

V. JURA (*Arch. Ital. di Urol.*, December, 1929, p. 520) considers that bacilluria, while far from rare in normal men and women, is slightly more frequent in pregnant women. There is little evidence that an ascending infection occurs, but the permeability of the intestines to micro-organisms, and the possibility of the passage of bacilli through the lymphatic connexions of the caecum and ascending colon with the right kidney, or through the blood, supports the view of the endogenous origin of the bacilluria which in pregnancy has been attributed to intestinal stasis. Jura, as the result of investigations of three series of 25 cases two months before labour, during labour, and one or two days after labour, found that 12, 10, and 13 cases respectively presented infected urine. In 103 cases investigated during and after labour, 26 had

infected urine during both periods, 10 only during labour, and 17 only after labour. These results, while confirming those of other investigators, show some difference in the occurrence of bacilluria during pregnancy and the puerperium as compared with its occurrence during labour, indicating that bacilluria increases slightly after labour. In all the cases examined urinary disease of any kind was proved to be absent. As the result of these and other detailed investigations, it is suggested that the occurrence of bacilluria during pregnancy or the puerperium is associated with intestinal conditions, and that with improvement in this respect the bacilli may even disappear. Moreover, the slight virulence and the small number of organisms eliminated by the kidneys are not likely to produce any lesion of the urinary system during pregnancy in the absence of local predisposing factors. Bacilluria, therefore, cannot be considered as a real disease; its symptoms are not at all definite, and [illegible] the microscopical examination of the [illegible] treatment alone is required, and urinary disinfectants and aperients, preferably paraffin, can be prescribed, ordinary disinfectants being used externally with advantage. In obstinate cases the filtrate of broth culture of the germs isolated from the patient (Besredka's method) may be administered orally, especially in the case of *B. coli*.

463. Haemostatic Serums in Haemorrhage.

A. TZANCK (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, November, 1929, p. 600) maintains that in cases of haemorrhage the amount of blood lost is not the only point to be considered; the rapidity with which it is lost is of primary importance. The practitioner rarely encounters a fulminating haemorrhage in time to help, and therefore the symptomatology of such cases can only be learned from experimentation. Tzanck has shown that when a trocar is introduced into the carotid of the dog, convulsions occur after the fortieth second, the pupils dilate, there is hyperextension of the legs, respiration ceases, and the animal dies in two minutes. In such cases the blood lost does not exceed 70 per cent. of the total amount in the body; the red corpuscles may number 5,200,000 per c.mm. at the beginning of the haemorrhage and 3,000,000 at the end of two minutes. He suggests that this reservation of the blood elements explains the satisfactory counts obtained after severe haemorrhage when the serum of Normet is used. In cases where haemorrhage is less rapid syncope is rare, convulsions exceptional, and consciousness is maintained although dyspnoea may be extreme. Such a haemorrhage may result in the loss of 90 per cent. of the blood volume, or may lower the red count to 1,500,000, before death occurs. He concludes that in fulminating haemorrhages any fluid capable of re-establishing the blood volume would save life by effecting a dilution of the blood elements which are being concentrated as a result of the syncope. For this purpose the efficacy of the various serums differs in degree only. In the less rapid haemorrhages, on the other hand, where more than 70 per cent. of the blood is lost and where a sufficient anaemia is caused, the serums fail, and blood transfusion alone is of use. To establish the real efficacy of such a serum its effective action would have to be made manifest in cases where more than 70 per cent. of the blood had been lost and where the red count had fallen to 1,500,000. Until this has been done the action of such a serum cannot be said to equal that of blood transfusion.

Pathology.

464. The Etiology of Psittacosis.

G. ELKELES (*Deut. med. Woch.*, April 11th, 1930, p. 619) describes some experiments on the etiology of psittacosis. According to his own observations the disease in parrots is characterized by diarrhoea, shivering, weakness, and apathy. If the bird survives this stage the diarrhoea ceases and the general condition and appetite improve. Respiratory disturbances may appear, accompanied by croaking noises and the secretion of mucus. As the result apparently of dyspnoea the bird may make convulsive efforts to fly, during which it strikes its head with great force on the roof of the cage, and dies of epidural haemorrhage. Starting with a bird that had survived the diarrhoeal stage but was still suffering from difficulty in breathing, the author tested various methods of propagating the disease. A parrot was brought into close contact with the sick bird; it developed diarrhoea in the third week and died after twenty days. The organs, with the exception of the liver, proved sterile on both aerobic and anaerobic cultivation; the liver contained markedly haemophilic bacilli resembling Pfeiffer's *influenza* bacillus, but differing from it in their formation of very tiny colonies, their weak resistance, their rapid loss of virulence, and the difficulty with which they could be carried over from one culture to another. The liver and intestine of this bird showed marked pathological lesions. An organ suspension—the liver excepted—was inoculated into another parrot, which died after thirteen days with liver lesions and pericarditis. All cultures from this parrot were sterile. Passage to another parrot proved fatal again in thirteen days. Starting from the original sick parrot, the author filtered organ suspensions through a Reichel D candle, and inoculated the filtrate into a normal parrot; this bird died in nine days with liver lesions and pericarditis. Two birds in the second passage died after eighteen and twenty-five days respectively. Of six birds in the third passage, three inoculated with unfiltered material died in six, seven, and eight days respectively, and one inoculated with a filtrate died in nine days; two inoculated with filtrates were still alive on the tenth day. The author concludes that the causative agent of psittacosis is filterable, and that it is infective for canaries as well as for parrots. Without committing himself to an opinion on the significance of the haemophilic bacilli found in some of the sick birds, he draws attention to the similarity of psittacosis with the severe nervous type of influenza. It is noteworthy that the haemophilic bacilli were found in the saliva of some of the sick parrots.

435 K. L. PESCH (*Münch. med. Woch.*, March 21st, 1930, p. 484) reports seven cases of psittacosis which occurred in Cologne; all the patients had had some association with lately acquired parrots, some of which died. Three families were affected, two members in each taking the disease. The remaining case was that of an employee in the shop which supplied parrots which were responsible for four of the cases. All seven patients were seriously ill and three died. Agglutination tests were performed with typhoid and paratyphoid bacilli, and two strains of psittacosis from the London Lister Institute, but all were negative, as were cultures on bile and broth. The urine showed no abnormality, but the sputa contained pneumococci and *Streptococcus viridans*, and in one case influenza bacilli were also present. The post-mortem material came from two patients only. In the first case *Streptococcus viridans* was found in the lungs; cultures of blood from the spleen and heart remained sterile; and a haemolytic strain of *B. coli* was found in the bile. In the second case pneumococci and non-haemolytic staphylococci were found in the lung as well as the *Streptococcus viridans*, but the blood was again negative. The material from these cases was used to experiment on parrots brought up in Germany and not previously exposed to infection; 15 were injected and 6 died. Their heart blood and the liver filtrate were again injected into fresh birds, one strain continuing until the sixth successive host; eventually 36 birds died. The parrot which had infected two of the human cases was put into a cage with 5 other birds, all of which died; by injection of their heart blood and liver extract (filtered or unfiltered) the virus was conveyed to fresh birds up to the third successive host. In two cases healthy birds were infected after living in an unsterilized cage in which another had died, proving that contact infection occurs. The result of the microscopic and cultural examinations of the material from the experiments on birds also proved negative, and the author concludes that neither *B. paratyphosus* nor the streptococcus is the causal organism of psittacosis, but probably a filter-passing virus is concerned.

465. Serum Protein Changes in Malaria and Typhoid Fever.

ACCORDING to R. B. LLOYD and S. N. PAUL (*Indian Journ. Med. Research*, October, 1929, p. 583) the typical protein graphs in typhoid fever and malaria both present the same characters, the most conspicuous of which is marked reduction of the serum albumin with rise of the euglobulin. The total globulin may be unchanged or slightly reduced, but not raised. The protein changes produced by T.A.B. vaccine are essentially the same though slighter in extent, the only difference being a raised total globulin figure. The protein fractions in typhoid fever begin to return to normal on defervescence, but the normal stage is not finally reached until long after the temperature has settled. In cases of relapse in typhoid fever the return to protein normality begins on the first defervescence, and the pyrexia of the relapse has no influence on the protein change. The authors maintain that in typhoid the period of low albumin and raised euglobulin represents the stage of immunization, and that only after immunization is complete does the return to protein normality commence. They conclude, therefore, that the pyrexia of a relapse in typhoid is unconnected immunologically with the primary attack. In view of the similarity of the malaria and typhoid protein graphs the question arises whether, despite the fact that the two diseases are causally so dissimilar, the conclusions drawn from the typhoid graphs may not have the same application to malaria.

"I have prescribed Agotan tablets, gr. 7½, to an elderly patient suffering from Rheumatoid Arthritis of the hip and knee-joint. She has derived great benefit, and her pains have been much relieved."

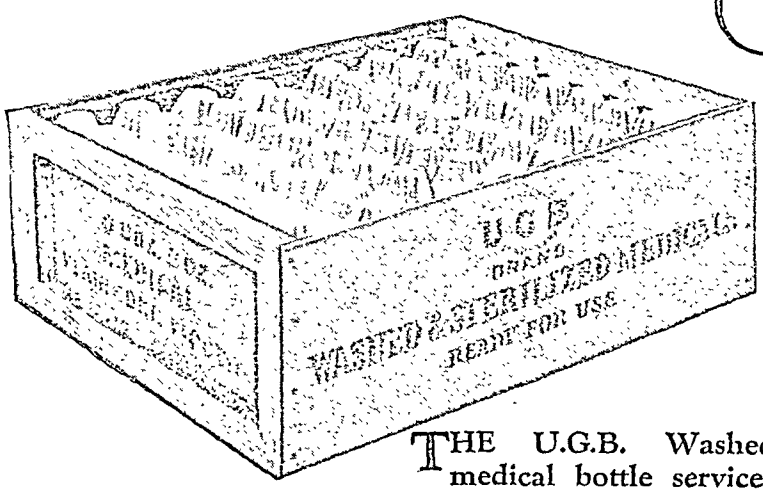
———, *M.B.*

"After trying radiant heat, diathermy, massage, ionisation, blister, and drugs galore, I took Agotan, with, I confess, little hope. The tablets acted like a charm, and in a short time I was able to get about and see my patients. I consider it most invaluable."

———, *L.R.C.P.I., L.R.C.S.I., etc.*

In RHEUMATISM, GOUT, SCIATICA, LUMBAGO, ARTHRITIS, NEURITIS, etc., where caused by excess of Uric Acid, AGOTAN (Howards) has proved a great boon to both patient and doctor.

Note:—HOWARDS' AGOTAN is excellent both in private and N.H.I. practice. The cost per head of treatment over a period is considerably less than most other remedies when results are taken into consideration.

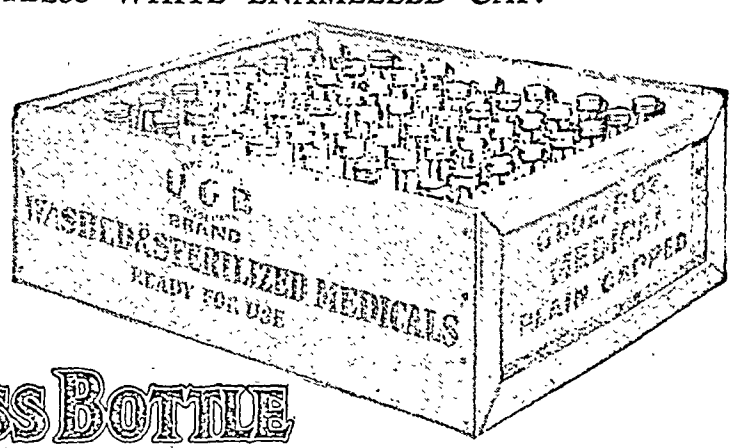


HOWARDS' AGOTAN is obtainable in Tablets, 7½ grains; in bottles of 25, 50, and 100; in 1-oz. bottles of Powder; and in tubes in a form suitable for local application.

Any reputable Wholesale House can supply or obtain.

Samples sent to medical men on application to the manufacturers:

HOWARDS & SONS LTD. (Est. 1797), Ilford, London



The U.G.B. MEDICAL BOTTLE Service

Photograph of actual package of Cork-mouth bottles with cover removed.

THE U.G.B. Washed and Sterilized medical bottle service—introduced early in 1929—has proved to be an unqualified success, so much so that we were recently compelled to increase the capacity of our washing and sterilizing plant.

The screw cap service is in particular demand, and owing to the preference of users for a cap in a neutral colour, we have now standardized in fitting the bottle with an attractive RUSTLESS WHITE ENAMELLED CAP.

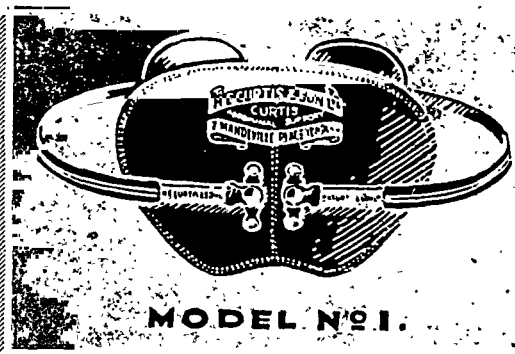
Salt and Son Ltd.

SALT'S REGISTERED
POST-MATERNITY BELT

Salt's Registered Post-Maternity Belt.

This belt is of entirely new design, registered and produced by ourselves, and accurately made to the measurements and particulars of the *medical man.*

It assists reduction of the body to normal size by perfectly natural corrective means, while the exact degree of support is always maintained. While the belt can gradually be reduced the elastic sides retain their correct positions.



We can supply this belt in various grades according to climatic conditions and in a wide range of qualities to meet the needs of all.

This, like all Salt's Appliances, is supplied under our well-known guarantee, which entirely protects the medical man from any financial liability, should it prove unsuitable or the patient refuse to wear it.

SALT AND SON LTD.
7, CHERRY ST., BIRMINGHAM.

DEAF DOCTORS

AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: "'Ardente' is a godsend to me"; without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many who are deaf use "ARDENTE."

"ARDENTE" is entirely different and unequalled and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, adjusted, and supplied.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

RATIONAL REPETITION IN THE TREATMENT OF RHEUMATISM

For many years Pistany has been appreciated by the Medical Profession for its great work in the cure of Rheumatism.

The properties of Pistany's hot volcanic soft mud are quite peculiar. Its power of stimulating and increasing the absorption of pathological products is still unrivalled.

The treatment may be continued by the patient after returning *from the Spa, under his own doctor's supervision,* by means of the Mud Packs, which are in use in many rheumatism clinics in this country.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.

Telephone: *Teignmouth* 289.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

The MAUDSLEY HOSPITAL
DENMARK HILL, S.E.5.

Telephone: RODNEY 4841—2.

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE MENTAL DISORDER. Voluntary patients ONLY RECEIVED.

OUT-PATIENTS—2 p.m.: MEN—Mondays and Thursdays. WOMEN—Tuesdays and Fridays.

IN-PATIENTS: (*a*) 164 beds (both sexes) in wards or separate rooms. (*b*) 13 private rooms (for ladies) with special sitting rooms, garden, and dietary.

Terms:

(*a*) **£5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.**

(*b*) **£6 6s. a week.**

Terms include (with rare exceptions) all forms of treatment, for which exceptional facilities exist—there being a staff of consultant specialists and the central laboratory of London County Mental Hospitals being attached to the hospital. Inquiries of EDWARD MAPOTHER, M.D., M.R.C.P., F.R.C.S., Medical Superintendent.

UNIVERSITY of CAMBRIDGE.
DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY (D.M.R. & E.).

The Course of study for the Diploma, which is open only to duly qualified medical men and women, begins on October 1st, 1930, and occupies nine months.

The first three months may be spent either in Cambridge (where the Physics is done in the Cavendish Laboratory and the Radiology and Electrology in the Department of Radiology), or in London (where the Physics is done at the Middlesex Hospital or King's College, and the Radiology and Electrology is taught at the British Institute of Radiology). These Courses run concurrently in Cambridge and London.

The *second three months must be spent in London*, where lectures are given at the British Institute of Radiology, and are combined with clinical instruction in the large teaching hospitals.

The third three months may be spent in recognized hospitals in London or elsewhere, the student acting as clinical assistant or in similar capacity.

The examinations consist of three parts, viz.:
1. Physics, with examinations in January and April.
2. Radiology and Electrology, with examinations in April and July.
3. The presentation of a thesis or exercise which is entirely the candidate's own work, and is intended to show that he has had practical experience of the subjects.

Further information as to the Courses may be obtained from:
G. SHEAD, M.A., Secretary for the Diploma, and Lecturer in Physics as applied to Medical Radiology, Cavendish Laboratory, Cambridge.
A. E. BARCLAY, O.B.E., M.A., M.D., Lecturer in Radiology, Department of Radiology, Medical School, Cambridge.
The Educational Secretary of the British Institute of Radiology, 32, Welbeck Street, London, W.1.

UNIVERSITY OF CAMBRIDGE
Diplomas in (*a*) PUBLIC HEALTH, (*b*) HYGIENE (for foreign graduates), (*c*) TROPICAL MEDICINE AND HYGIENE.

Courses of Instruction in the Subjects of the Examinations commence October 8th, 1930. Full particulars to be obtained from Mr. J. E. PURVIS, Public Health Chemical Laboratory, Medical School, Cambridge.

University of Birmingham.
INGLEBY LECTURE, 1930.

The Ingleby Lecture will be delivered on THURSDAY, MAY 22nd, at 4 o'clock, in the Medical Lecture Theatre (Edmund Street Buildings), by Sir JOHN BLAND-SUTTON, Bart., LL.D., D.Sc., M.D., F.R.C.S., Consulting Surgeon to the Middlesex Hospital, London.

Subject: "*The Blood Trail.*"

Members of the Medical Profession are invited to attend.

London Hospital, E.

University of London.
LAURA DE SALICETO STUDENTSHIP.

The Senate of the University of London invite applications for the LAURA DE SALICETO STUDENTSHIP FOR THE ADVANCEMENT OF CANCER RESEARCH, value £150 a year for not less than two years.

Applications should reach the University not later than July 1st, 1930. Further particulars may be obtained from the Academic Registrar, University of London, South Kensington, S.W.7.

Essex County Council.
BLACK NOTLEY SANATORIUM.

APPOINTMENT OF DISPENSER-CLERK (Female).

The County Council of the Administrative County of Essex invite applications from fully qualified persons for the above appointment at their Sanatorium for the treatment of Tuberculosis at Black Notley, near Braintree. The Sanatorium provides accommodation for the treatment of approximately 180 cases of pulmonary and non-pulmonary tuberculosis in women and children.

The person appointed will be required to reside at the Institution, and the salary will be at the rate of £160 per annum, plus board, residence, and laundry, and will rise, subject to satisfactory service, by annual increments of £10 to a maximum of £150 per annum.

The appointment will be subject to one month's notice on either side.

Applications should be made to the County Medical Officer of Health, Prudential Buildings, Duke Street, Chelmsford, on or before Monday, May 26th.

Shire Hall, Chelmsford. May 9th, 1930. JOHN H. GOOLD, Clerk of the County Council.

Cumberland County Council.
ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from fully qualified Medical Men holding a Diploma in Public Health.

Salary commences at £600 per annum, rising by annual increments of £25 to £700, with travelling and subsistence allowance.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, terminable by two months' written notice on either side, and the person appointed will be required to pass a medical examination and to devote the whole of his time to his duties under the supervision of the County Medical Officer of Health.

Forms of application may be obtained from the County Medical Officer, Citadel Chambers, Carlisle, on receipt of a stamped addressed foolscap envelope.

Applications, endorsed "Assistant Medical Officer," and accompanied by copies of three recent testimonials, must be received by the County Medical Officer of Health not later than Thursday, June 5th.

Canvassing is a disqualification.

C. W. ALLAN HODGSON,
Clerk of the County Council.
County Offices, Carlisle. May 12th, 1930.

Berkshire County Council.
ASSISTANT TUBERCULOSIS OFFICER AND GENERAL MEDICAL ASSISTANT.

Applications are invited for the above combined appointment. Salary £600 per annum. The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922. Candidates must be qualified to hold an appointment as Tuberculosis Officer as required by the Local Government (Qualifications of Medical Officers) Regulations, 1930, and must also have a Diploma in *Public Health*. Forms of application and full particulars may be obtained from the Clerk of the County Council.

Applications, accompanied by three testimonials, must reach the undersigned on or before Saturday, May 31st.

H. J. C. NEOBARD,
Clerk of the County Council.

Warwickshire and Coventry JOINT COMMITTEE FOR TUBERCULOSIS.

MEDICAL SUPERINTENDENT OF THE WARWICKSHIRE KING EDWARD VII MEMORIAL SANATORIUM, HERTFORD HILL, near WARWICK. (195 Beds.)

Applications are invited from male qualified and registered Medical Practitioners for the post of Medical Superintendent of the Warwickshire King Edward VII Memorial Sanatorium, Hertford Hill, near Warwick. The person appointed must devote the whole of his time to the duties of the office, and must have had special practical experience in the treatment of tuberculosis in sanatoria, dispensaries, and otherwise; and must be thoroughly acquainted with modern methods of diagnosis and treatment.

In addition applicants must have held the appointment of Tuberculosis Officer or Medical Superintendent with the approval of the Minister of Health, or who, subsequent to qualification:

(1) have had at least three years' experience in the practice of his profession;

(2) have spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical or surgical cases; and

(3) have received special training, for a period of not less than six months, in the diagnosis and treatment of tuberculosis.

The salary is at the rate of £800 per annum, plus unfurnished house, including fuel, light, and laundry, valued at £100 per annum, but not board. The salary will be subject to a deduction of 5 per cent. in respect of contributions under the Local Government and Other Officers Superannuation Act, 1922; in addition, motor car allowances in accordance with the Committee's scale and reasonable travelling expenses are paid.

The appointment is also subject to a satisfactory medical examination by one of the Committee's independent Medical Referees.

Forms of application and statement of the duties and terms of the appointment can be obtained from the undersigned. Applications, marked "Medical Superintendent," with copies of not more than three recent testimonials, must be received by me not later than Monday, May 26th.

Applicants must not be over 40 years of age. Canvassing, directly or indirectly, will be considered a disqualification.

L. EDGAR STEPHENS,
Clerk of the Joint Committee

42, Warwick Street,
Leamington.
April 28th, 1930.

County Borough of Rotherham.

ASSISTANT MEDICAL OFFICER OF HEALTH

The Rotherham Corporation invite applications from duly qualified and registered Medical Practitioners for the position of Assistant Medical Officer of Health with principal duties relating to Venereal Diseases, and Maternity and Child Welfare. The Officer appointed will also act as Medical Officer to the Municipal Maternity Home. Preference will be given to candidates holding the Diploma of Public Health. Salary £700.

The gentleman appointed will be required to devote the whole of his time to the duties of the office and to reside in the Borough, and will not be allowed to engage in private practice, and all emoluments or fees which may be payable to or received by him will have to be paid to the Corporation.

The appointment will be subject (1) to the passing of a medical examination, (2) to the provisions of the Sanitary Officers Order, 1926, (3) to be subject to the Local Government and Other Officers Superannuation Act, 1922, and (4) to termination by three months' previous notice.

A list of duties can be obtained from the Medical Officer of Health.

Canvassing, either directly or indirectly, is prohibited.

Applications, with copies of not more than three recent testimonials attached, to be sent to me, endorsed "Assistant Medical Officer of Health," not later than May 26th.

CHAS. L. DES FORGES,
Town Clerk.

Municipal Offices, Rotherham.
May 7th, 1930.

West Suffolk General Hospital, BURY ST. EDMUND'S. (108 Beds.)

Applications are invited for the post of JUNIOR RESIDENT MEDICAL OFFICER (male or female). Salary £120 per annum, with board, residence, and laundry.

Applicants must be fully qualified and registered. Applications, giving particulars of experience, and enclosing three recent testimonials, should be addressed to the undersigned.

Applications must be received not later than May 24th, 1930.

E. J. HARDWICKE,
Secretary.

City of Birmingham. SELLY OAK HOSPITAL.

CASUALTY OFFICER (Male).

Applications are invited from fully qualified Medical Practitioners for the appointment of Casualty Officer (male) at the Selly Oak Hospital, Birmingham.

The present Hospital accommodation is 550 beds, divided into General, Medical, General Surgical, Gynæcological, Obstetrical, and Children's Disease sections. There are completely equipped Pathological and Biochemical Laboratories and X-ray, Electro-therapeutic, Massage, Ultra-violet Ray and Electro-cardiographic Departments. Over 3,000 operations are performed annually.

The appointment will be for a period of six months in the first instance, but may be extended at the end of that time.

The person appointed will be required to assist at operations, to administer anæsthetics, and to undertake casualty and such other duties as may be assigned to him by the Medical Superintendent.

The salary attached to the appointment is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

Further particulars of the appointment may be obtained from the Medical Superintendent, R. P. STANLEY KELMAN, Esq., M.B., F.R.C.S. (Eng. and Edin.); at the Selly Oak Hospital, to whom applications, stating age, experience, and qualifications, should be forwarded not recent testimonials, accompanied by copies of later than Wednesday, May 28th.

F. H. C. WILTSHIRE,
Town Clerk.

Borough of Chelmsford.

MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified Medical Practitioners possessing the Diploma of Public Health for the appointment of Medical Officer of Health of the Borough, subject to the provisions of the Public Health (Officers) Act, 1921, and the Sanitary Officers Order, 1926.

The gentleman appointed will be required to perform all the duties generally appertaining to the position of Medical Officer of Health, to act as School Medical Officer, to undertake work in connection with Maternity and Child Welfare and to carry out all such duties as the Council may from time to time direct. He will be required to reside in the Borough unless otherwise authorised by the Council, and must devote his whole time to the duties of the office and must not engage in private practice.

He will also be required to undertake work in connection with the Chelmsford Joint Hospital, for which the Chelmsford Joint Hospital Board will pay £100 per annum.

The salary to cover all the duties specified above (including the payment by the Joint Hospital Board) will be £800 per annum.

Full particulars and terms of appointment may be obtained upon application to the undersigned, and applications on the form forwarded should reach me not later than June 11th.

Canvassing will be a disqualification.

G. E. BARFORD,
Town Clerk.

Municipal Offices,
Ramsford House,
Chelmsford. May 9th, 1930.

Derbyshire Education Committee

ASSISTANT SCHOOL MEDICAL OFFICER (Male).

The Derbyshire Education Committee require the services of an Assistant School Medical Officer (male) at a salary of £600, rising by annual increments of £25 to £700 per annum.

The candidate must be a registered Medical Practitioner of at least three years' standing. The duties will include work under the Maternity and Child Welfare service. Experience in this work and in the administration of anæsthetics is essential.

The appointment will be a designated post under the Local Government and Other Officers Superannuation Act, and the successful candidate will be required to pass a medical examination.

The officer appointed will not be allowed to engage in private or consulting practice, but will be required to devote his whole time to the duties of the office, and will act under the direction of the School Medical Officer.

Forms of application may be obtained from the undersigned, to whom they should be returned completed, together with copies of not more than three recent testimonials, on or before Monday, May 26th, endorsed "Assistant School Medical Officer."

The appointment will be determinable by three months' notice on either side.

W. M. ASH,
School Medical Officer.

New County Offices,
St. Mary's Gate,
Derby. May 5th, 1930.

City of Plymouth. DEPUTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered Medical Men for the post of whole-time Deputy Medical Officer of Health to the City of Plymouth.

Applicants must possess a Diploma in Public Health or a qualification in State Medicine.

The salary will be at the rate of £750 per annum, rising by annual increments of £50 to £900 per annum, and the appointment will be terminable by three months' notice on either side.

The person appointed will be required to act for the Medical Officer of Health in his absence and generally to help him in the Public Health work of the City, and in the various Sub-departments of the Public Health Department. He will act under the general supervision and direction of the Medical Officer of Health, and carry out any duties delegated to him from time to time.

Forms of application will not be provided. Candidates for this appointment should state their age and give an account of their professional qualifications and experience in all branches of Public Health work.

Canvassing will disqualify the applicant.

Applications must be received by the undersigned on or before Thursday, June 5th, and envelopes must be endorsed "Deputy Medical Officer of Health."

A. T. NANKIVELL, M.D., M.R.C.P., D.P.H., Medical Officer of Health, City and Port of Plymouth

Town Hall,
Stonehouse,
Plymouth.
May 8th, 1930.

City of Plymouth. RESIDENT MEDICAL SUPERINTENDENT.

Applications are invited from duly qualified and registered Medical Practitioners for the post of Resident Medical Superintendent of the Plymouth City Hospital.

The salary will be at the rate of £1,000 per year, with food, quarters, lighting, heating, and washing. No canvassing for this appointment is permitted, and any canvassing will disqualify the applicant. The appointment will be terminable by three months' notice on either side.

Applicants must be holders of the F.R.C.S. or the Degree of a Master of Surgery in a University of the United Kingdom. The appointment is whole-time, and private practice is not permitted. The person appointed will be an Assistant Medical Officer in the Public Health Department, and will be on the staff of the Medical Officer of Health, who is the General Medical Superintendent of the Corporation Hospitals.

Applications will be considered only on the forms of application which will be provided. A form of application, together with further details relating to the appointment, can be obtained from the undersigned, on the receipt by him of a request for this, accompanied by a stamped and addressed envelope. Forms of application, duly completed, together with copies of not more than three recent testimonials, must be returned to the undersigned not later than June 5th.

A. T. NANKIVELL, M.D., M.R.C.P., D.P.H., etc., Medical Officer of Health.

Town Hall,
Stonehouse,
Plymouth.
May 8th, 1930.

County Council of Nottingham-SHIRE.

ASSISTANT MEDICAL OFFICER FOR SCHOOL MEDICAL INSPECTION AND FOR MATERNITY AND CHILD WELFARE (Woman).

Applications for the above-named appointment are invited from duly registered women Medical Practitioners who have had at least three years' experience since obtaining registrable qualifications and who hold a Diploma in Public Health.

Preference will be given to candidates with previous experience of the work, particularly as regards Mental Deficiency, Refractions, and Ante-natal work.

The salary will be at the rate of £600 per annum, with travelling expenses in accordance with the County Council Scale. The appointment will be a whole-time one. The candidate appointed will be a member of the staff of the County Medical Officer, will work under his control and direction, will be required to reside in a part of the County to be approved by him, and to carry out such duties as may be prescribed.

The successful candidate will be required to pass a medical examination and to contribute to the Council's Superannuation Fund.

Forms of application may be obtained from the undersigned, and should be returned, accompanied by copies of not more than three recent testimonials, to the County Medical Officer, Shire Hall, Nottingham, on or before May 21st.

K. TWEEDALE MEABY,

City of Manchester.

The Public Health Committee of the Corporation require the services of a fully qualified Whole-time WOMAN MEDICAL OFFICER, experienced in midwifery and children's diseases, to hold (under the direction of the Medical Officer of Health) consultations and infant clinics at the Maternity and Child Welfare centres of the Manchester Corporation, and under the like direction to perform such other duties as appertain to the office.

The salary will be £600 per annum. A statement of the duties and conditions of office may be had on application, in writing, to the Medical Officer of Health, Civic Buildings, Mount Street, Manchester.

Applications stating age and experience, and endorsed on the envelope "Medical Officer, Child Welfare," must be sent in addressed to the Town Clerk only, and not to members of the Committee or Council, not later than Saturday, May 24th, and be accompanied by not more than three recent testimonials.

The successful candidate will be required to contribute to the Corporation Superannuation Fund, and to execute their deed of service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

F. E. W. HOWELL,
Town Clerk.

1 SOMERSET.—Attractive Town, within easy reach of coast.—Old-established and increasing PRACTICE, producing for the immediate past twelve months over £3,000, including panel of 1880, and appts. worth about £250. Fees 2/6 to 21/-. Cottage Hospital, and good surgical scope. Two very suitable houses available at very moderate rents. Sport of all kinds. Premium £4,500.

2. WITHIN TEN MILES OF GLASGOW.—CLEAN TOWN.—Old-estab. good middle and better-class PRACTICE, producing an average of nearly £2,950 p.a., including panel of 2,300 and appts. worth £500. Fees 2/6 to 21/-, medicine extra. Mid. from 2 gns. upwards. Very good detached house, with 3 reception, 5 bedrooms, etc. Garden. Garage. Can be purchased, or other residence secured. Premium 1½ years' purchase, £1,500 down, and balance as arranged.

3. PARTNERSHIP.—MIDLANDS.—COUNTY TOWN.—TWO ONE-FIFTH SHARES (suitable two friends or will be sold separately) are offered in a very old-established good-mixed Practice owing to the retirement of the senior of two partners. Gross cash receipts for immediate past 12 months over £5,900, including panel of 3,400. Fees from 4/-. Not much midwifery. Good house, with 2 reception, 6 bedrooms, etc. Rent on lease £75 p.a. Premium for share two years' purchase.

4. LONDON, EAST.—Old-estab. mainly working-class PRACTICE, producing over £1,800, including panel of 2,500. Suitable small house, with one reception, 3 bedrooms, etc. Garden. Rent on lease £50 p.a. Premium £3,500.

5. SOUTH-WEST COAST.—VERY FAVOURITE RESORT.—Old-established good middle-class non-panel PRACTICE, held by Vendor (who is retiring) over 20 years. Receipts average £1,142. Fees 5/- to 10/6 and upwards. Mids. 5 to 15 gns. (about 12 cases). House is an exceptionally good one, in perfect order, with ample accommodation, central heating, electric light. Good garden. Garage. Price for freehold £3,250. Premium 1½ years' purchase.

6 CORNISH RIVIERA.—Old-established good mixed PRACTICE in exceptionally attractive village which is steadily increasing. Receipts for last 12 months £1,300, including panel of over 400. Visits 5/- to 21/-. Excellent house, facing due south, with 6 bedrooms, etc. Good garden. Rent on lease £56 p.a. Premium £1,800.

7. YORKS (NORTH RIDING).—In a small pleasant market town, with pretty and prosperous surrounding country, very old-established mixed-class PRACTICE averaging £1,247 p.a., including appts. worth £80 and panel producing last year £366. Visits 3/6 to 25/-. One opponent. Good house, facing south (3 reception, 5 bedrooms, bathroom, etc.). Garden. Garage. Electric light. Vendor's freehold. Price £1,350 (£1,000 on mortgage), or would let for few years at £80 p.a. Premium £1,500. Educational and social amenities.

8. SOUTH YORKS.—GOOD TOWN. — Old-established good middle-class PRACTICE, producing for last twelve months nearly £4,500. Small selected panel of 400. Fees 5/- to 10/-. Mid. 2 to 10 gns. (only about 50 cases yearly). Suitable house, with 3 reception, 6 bedrooms, etc., and professional rooms. Electric light. Good garden. Garage for 3 cars. Rent on lease £100 p.a. Excellent schools, sport, etc. Premium £5,700.

9 NORTH DEVON.—DEATH VACANCY.—Well-established mixed-class PRACTICE, in delightful district, producing £670 p.a., including panel of 417. Visits 3/6 to 10/6. Suitable house, with 2 reception, 4 bedrooms, and maids' rooms, etc. Garden. Price for freehold £1,300. Sport of all kinds. Premium £700. Scope for increase, and surgery.

10 KENT.—Pleasant Seaside and residential Town (pop. 17,000).—Old-estab. non-dispensing middle and working-class PRACTICE, averaging for the past 3 years over £1,050 p.a. including transferable appt. worth about £200 and panel of 500. Visits 3/6 to 10/6. Very little midwifery. House contains 8 rooms, kitchen, bathroom, etc. Garden. Garage. Price freehold £1,500, but might be rented. Premium £1,500.

11 DEATH VACANCY.—CORNWALL.—Good mixed general PRACTICE, in very pretty district, producing over £1,200 p.a., including panel of 845. Fees from 2/6. Mids. from 2 gns. Rent of Surgery 15/- per week. Small house available, rent £20 p.a. Premium £850, payable £200 down and balance of yearly instalments of £150. Efficient locum in charge.

12 DEATH VACANCY. — HARROGATE. — Well-established PRACTICE, averaging about £600 p.a., including panel of 500. Fees 3/6 to 21/-. House contains 2 reception, 5 bedrooms, etc. Price £1,000, or might be rented. Moderate premium. Locum in charge.

13 CITY CONSULTING PRACTICE.—Receipts for the past 12 months nearly £600 and rapidly increasing. Fees 10/6 and 21/-. One appointment worth £25 p.a., and believed to be transferable. Two good rooms, with communicating passage and own front door, in perfect order. Rent £200 p.a. Illness reason for sale.

14 FAVOURITE SUSSEX COAST TOWN.—Small middle-class PRACTICE, non-panel, and averaging nearly £300 p.a. Visits 3/6 to 7/6. No midwifery. Suitable freehold house. Garden. Coach-house and stabling. Price £1,300. Premium £300. Vendor retiring.

15 LINCS.—Very old-established easily worked Village PRACTICE, averaging £1,535 p.a., including panel and appts., producing £740 p.a. Fees from 2/6. Not much midwifery. Nearest opponent 6 miles. Suitable house, with 3 reception, 4—5 bedrooms, bathroom, etc. One acre of garden. Price £900. Good sport and schools within reach. Premium 1½ years' purchase. Cottage Hospital.

16 SUSSEX.—Unopposed Village PRACTICE, old-established, in delightful surroundings, producing about £1,100 p.a., including panel of 545 and capable of considerable increase. Exceptionally charming residence, standing in 3½ acres of well-laid-out garden, tennis court, etc., and containing lounge hall, 2 reception, 7 bedrooms (3 fitted h. and c. water basins), dressing and 2 bathrooms, etc. Central heating. Electric light. Garage. Price for Practice and house £5,000.

17. MANCHESTER.—PRACTICE is situated in a growing district offering very large scope. Income about £1,700 p.a., including panel producing £450. Fees 3/6 upwards. Excellent detached house, well situated, with 3 reception, 5 bedrooms, etc., all in good order. Price £1,800. Premium 1½ years' purchase.

18. HANTS.—COUNTRY PRACTICE.—Very old-established, situated in most attractive district near Sussex Border. Receipts average over £800 p.a. Panel of 480. Detached house in half an acre of garden, 2 reception, 5 bedrooms, etc. Rent £55 p.a. Hunting, golf, etc., and first-class schools within reach. Premium £1,300.

19. LONDON, SOUTH-WEST.—Very old-established non-residential PRACTICE, averaging about £4,000 p.a. Panel of 1,500, but large scope for more. Fees 2/6 upwards. Suitable house or flat can easily be obtained to meet purchaser's requirements. Rent of surgery on long lease £100 p.a. Premium 1½ years' purchase.

20. YORKS.—In a clean and thriving manufacturing town, an old-established Homœopathic and partly Allopathic PRACTICE, held about 50 years by Vendor who is retiring. Cash receipts for the past three years average £2,400 p.a. Patients middle and better-class. Midwifery refused. Good house available, rent £100 p.a. Premium only one year's purchase, part down and balance by arrangement.

21. LANCS.—LARGE TOWN.—Very old-established good industrial class PRACTICE, producing £2,500 p.a., including panel of 1,804, and appts. worth about £120 p.a. Fees 2/6 upwards. Very suitable for two friends in partnership, as two houses available. Good sport and schools. Premium 1½ years' purchase. A one-half share will be offered with view to succession in six or twelve months if desired.

22. [illegible] wn within easy reach of Manchester.—[illegible] producing £2,600 p.a., with panel of [illegible] fees 2/6 to 5/5, medicine extra. Good house, with ample accommodation. Price £1,000, or would be rented at £70 p.a. Premium 1½ years' purchase, half down and balance by instalments.

23. SOUTH OF ENGLAND.—LARGE SEAPORT TOWN.—Old-established mixed general PRACTICE. Average income nearly £1,900. Panel of 2,500. Fees 2/6 to 7/-. No mids. No Assistant kept. Well situated house, with good accommodation. Rent on lease £120. Prem. £3,500.

24. WITHIN 40 MILES OF LONDON.—In a thriving Riverside and Hospital town (pop. over 40,000).—Old-established mixed-class and increasing PRACTICE worth over £2,300 last year, including panel of 1,600 to 1,700. House contains professional accommodation, 2 reception, 4 bedrooms, bathroom, etc. Small garden and garage. Rent on lease £60 p.a. Premium £3,650, to include good book debts of £500, drugs, etc., and consulting room and surgery furniture.

25. BORDERS OF BERKS AND HANTS.—In a delightful district, an old-established mixed-class PRACTICE averaging for the past three years £904 p.a. (last year £973), including panel of 400. Visits 5/- to 12/6, medicine extra (3/6). Very little midwifery. One opponent. House contains ample accommodation (2 sitting rooms, 7 bedrooms, bathroom, etc.). Large garden and garage. Water laid on and gas plant installed. Rent £50 p.a. Premium £1,400. Excellent sport.

26. PARTNERSHIP.—WEST MIDLANDS.—The Third share (with increase to half in 4 years and eventual succession if desired) is offered in very old-established mixed-class Practice in small town, largely residential, in midst of agricultural district of exceptional beauty. Cash receipts average £2,367 p.a., including panel of 1,084. Opposition not strong. Expenses light. Choice of two houses (small) which can be bought for £600 or £700. Premium 2 years' purchase.

27. SURREY.—In a beautiful residential district within 40 miles of London (good train service) a small mixed-class PRACTICE worth about £600 p.a. and offering scope. Select panel of 200. Charming house with ample accommodation in very pretty grounds (tennis court, etc.) of 1¼ acres. Price, freehold, £3,500. Premium 1½ years' purchase.

28. WITHIN FIFTY MILES OF LONDON.—In a pretty residential district, a well-established PRACTICE averaging over £700 p.a., including panel of 538, and appts. worth about £60. Visits 3/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (3 reception, 5 bedrooms, etc.), with large garden, tennis court. Garage. Elec. light. Price for freehold £3,000. Premium £1,050. Exceptionally good educational facilities for boys.

29. PARTNERSHIP.—In a most desirable outlying residential suburb a suitable Partner (University Graduate, Oxon. or Cambs., experienced, 30 to 35 years of age and married preferred) can acquire a share (producing at first about £1,200 p.a., but larger might be considered, with further shares up to a third at arranged intervals) in an old-established good mixed-class Practice, averaging over £10,000 p.a. Very good house, with ample accommodation, garden, etc., on rental. Premium 2 years' purchase. Short preliminary assistantship essential.

30. SOUTH-WEST OF ENGLAND.—ATTRACTIVE COAST TOWN.—PARTNERSHIP.—A one-third share is offered, owing to the retirement of the second of three partners, in an old-estab. good mixed Practice, having good surgical scope. Gross cash receipts average £4,000, including panel of about 1,800. Suitable house available on rental. Premium for share only 1½ years' purchase, part down and balance as arranged.

Full Schedule of Terms and Conditions will be forwarded on application.

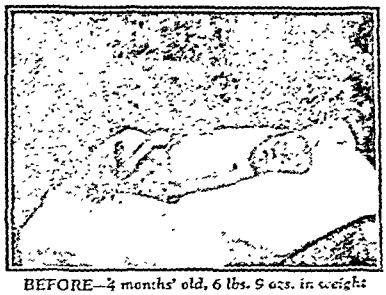
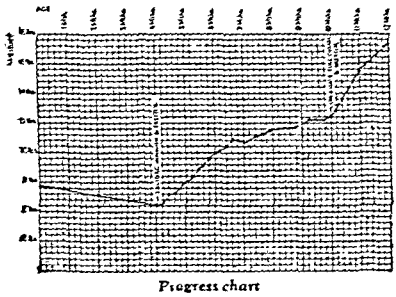
NATURALLY RICH

IN VITAMIN "D"



A "RESURRECTION"

THE mother of Baby "H" wrote to our Motherhood Bureau when he was 4 months' old (weight only 6 lbs 9 ozs.) suffering from Marasmus following Whooping Cough complicated by Double Pneumonia. The infant was put on to LACIDAC (Separated) with a small quantity of *BRESTOL* and immediately made steady progress.



At 6 months he had gained 3 lbs. 7 ozs. and by the end of another 4 months his weight was 12 lbs. 6 ozs., and progress was so good that it was possible to change him gradually on to Cow & Gate Full Cream and Brestol.

He has now cut teeth quite successfully and at the age of 10 months is taking normally to mixed feeding and is a happy, lively baby.

His Doctor considers him a '*Resurrection.*'

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight

The "DAVON" (Reg.) Latest Specialities.

EAR, NOSE AND THROAT OUTFIT.

No. 601C. Outfit, comprising—

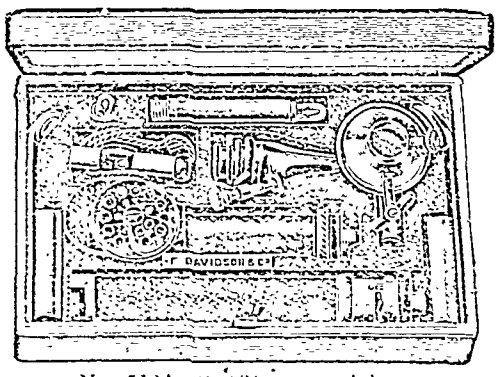
ELECTRIC LARYNGO-PHARYNGOSCOPE

With an optical system giving a greatly improved view which can be rotated as in a cystoscope so as to bring into view the pharyngeal nares, the larynx, epiglottis, the vocal chords, and the Eustachian tubes. A suitable catheter in position is easily observed.

ELECTRIC AURISCOPE

for diagnosis, operating, aspirating, and massage, with three sizes of aural speculae and expanding nasal speculum 3-volt Battery (not the "Davon") in Handle and Inflator in Oak case ... £8 15 0

No. 601B. *Pharyngoscope*, with Battery in Handle, £5 15 0
Or in Oak case £6 5 0



No. 512B. *Auriscope*, complete as above with Battery in Handle in Oak case £4 5 0

No. 95. *Oak Case*, containing "*Davon*" *Dry Battery, Rheostat* and *Special Switch Handle*, fitting any of the above instruments £1 12 6

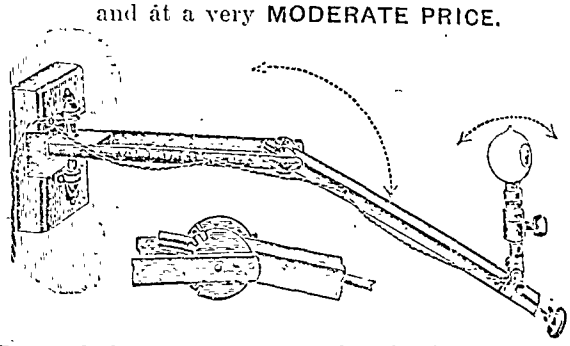
These outfits with battery in handle make a self-contained equipment in very portable form for visiting purposes, and the addition of No. 95 furnishes a very reliable source of illumination in one's consulting room.

No. 601. *Laryngo-Pharyngoscope* alone with Switch Handle and Cords £5 15 0

No 691A. Ditto, with "Davon" Dry Battery and Rheostat, all contained in Walnut case (similar to No. 95) £7 5 6

No. 512A. Outfit, comprising—

New Lighting Tube, 2 Mirrors, fitting with 3 Aural and 1 Nasal Speculae, Magnifier, the "Davon" combined Electric Ophthalmoscope and Retinoscope, 3-volt Battery in Handle, etc.



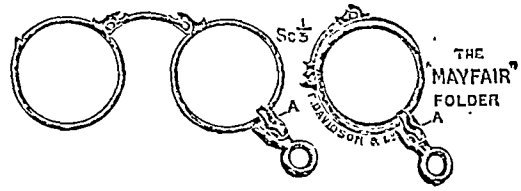
Size 7½" × 4½" × 2". Price, complete £9 0 0

No 512, without Ophthalmoscope, size 6½" × 4½" × 2". Price £5 5 0

Other Outfits from ... £3 3 0

THE "DAVON" BRACKET.

Well made and serviceable and at a very MODERATE PRICE.



By a slight pressure upon the ebonite knob (seen below the lamp) a clutch is caused to disengage from one of a series of teeth in the discs visible at the hinge; by releasing the pressure the clutch is self-locking in the position the lamp is desired to assume. One hand only is necessary to adjust, and when not in use the lamp will fold flat to the wall.

Price without bulb £2 2 0.

Target frosted bulbs (please state voltage), each 3/6.

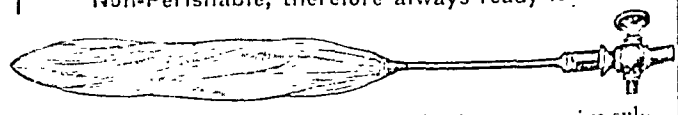
THE "HANDY" READING GLASSES.

Beautifully made in either Real or Imitation Tortoise-shell. Much handier than any other type of frame for reading.

It can be opened and placed on the nose with one hand. A slight pressure on the spring catch "A" immediately releases the two eyes as in a lorgnette, and with the forefinger on the bridge and a little downward pressure the "Mayfair" Folder immediately takes up its position on the nose.

With suitable lenses it can be used alone or in addition to one's distance glasses.

Price, without lenses, in Real Shell ... £2 10 0
Ditto, in imitation shell £1 1 0



OCULISTS' TRIAL CASES

with Davidson's Improved Complete Sight Test Card, and Instructions, from £10 10 0

(Second-hand cases generally in stock.)

IMPROVED EPISTAXIS PLUG.

Non-Perishable, therefore always ready for use.

Can be washed in hot water, carbolic or corrosive sublimate solutions. Gives a more even pressure when inflated than any other.

Supplied with 1 Bulb and 1 Inflator. Price 10/6.

The Treatment of Hay Fever

When prophylactic immunization with pollen vaccine has not been carried out it is still possible to afford considerable relief to hay-fever patients by suitable treatment. The preparations listed below, having been found effective in the hands of many physicians, are suggested for this purpose.

"POLLACCINE"

A vaccine prepared in the Department for Therapeutic Inoculation of St. Mary's Hospital, London, from the pollen of timothy grass *(Phleum pratense)*. Has usefully been employed during attacks of hay fever, though preventive treatment is more to be recommended. Physicians interested are invited to write for details.

ADREPHINE.

A solution which supplies the prompt vigorous action of adrenalin with the more sustained effect of ephedrine. The outstanding indication for Adrephine is the relief of congested mucous membrane, hence its utility in hay fever. Applied by means of the 'Glaseptic' Spray.

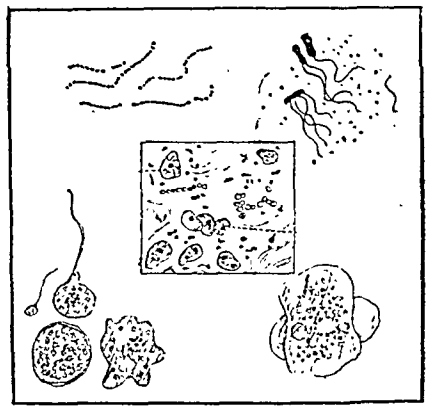
Supplied in vials of 10 c.c. and bottles of 1 oz.

ANESTHONE CREAM.

An analgesic and astringent ointment containing 10 per cent. of anesthone (para-amido-ethyl-benzoate) with 1 in 20,000 Adrenalin Chloride in a bland, oleaginous base. This cream affords prompt, decided, and prolonged relief from the irritation and inflammation of hay fever.

Supplied in collapsible tubes.

ADRENALIN INHALANT.



This is a 1 in 1,000 solution of Adrenalin Chloride in aromatised, neutral oil containing 3 per cent. of Chloretone; applied as a nebula, it is one of the best available topical applications for symptomatic relief of hay fever. The 'Glaseptic' Pocket Nebulizer allows easy and regular application by patients.

Supplied in bottles of 1 fluid ounce.

PARKE, DAVIS & COMPANY 50 BEAK ST., LONDON, W.1

Laboratories Hounslow Middlesex *Inc U.S.A. Liability Ltd*

When the Colon Bacilli Revolt

WHEN the normally non-pathogenic colon bacilli rebel under the influence of foreign invaders or because of the putrefaction and toxæmia resulting from constipation and fæcal impaction, the consequences may be grave in the extreme.

The logical treatment is obviously preventive. In all cases of chronic constipation, incipient stasis or fæcal impaction, and in certain forms of intestinal toxæmia, prompt and efficient evacuation, followed by gradual resumption of normal bowel action, will be obtained by the use of AGAROL Brand Compound, *the original agar-agar emulsion.*

A generous trial quantity sent on request

FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* mineral Oil — Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

SOLID IODINE

Safe—useful—portable

The manifold uses of H_2O_2 are known to all members of the medical profession. 'Peroxtik' is the only solidified form of Peroxide of Hydrogen in existence. Its utility, portability and safety is obvious, and every tube is guaranteed to maintain its original 10-volume strength for a reasonable period. Medical men interested in H_2O_2, who are desirous of testing 'Peroxtik,' should not fail to write for a free sample tube to ARTHUR H. COX & Co., LTD., 93, Lewes Road, Brighton.

'Peroxtik'

SOLIDIFIED PEROXIDE OF HYDROGEN

in neat, handy glass tubes.

INTESTINAL SUBINFECTION

SALVITAE is the key whereby the physician may control elimination and alkalinization, thus dealing fundamentally and effectively with Intestinal Subinfection, Toxæmia, Acidosis, Uric-acidæmia, and Constipation.

It is indicated in a large number of disorders characterized by, and more or less dependent upon, faulty metabolism, imperfect elimination, and disturbances of the acid-base equilibrium of the body.

Samples and Literature on request to Sole Agents: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

A formula that demonstrates its scientific value.

Salvitae

Two sizes, 4/6 and 7/-.

Manufactured by American Apothecaries Co., New York.

DIABETES

Brusson Bread has the lowest starch content of any starch-reduced gluten bread.

This low starch content enables a fuller and more varied diet to be enjoyed by the patient. Its scientifically graded content of protein and fat is definitely fixed, so enabling the physician to prescribe the correct quantity for each patient.

BRUSSON FOODS LTD

55 STATION Rd LONDON N.W.10

Free samples on request, with copy of "The Amplified Diet in Diabetes," often useful for handing to patients.

NEW PUBLICATIONS.

INSOMNIA
AN OUTLINE FOR THE PRACTITIONER

By H. CRICHTON-MILLER, M.A., M.D.Edin. & Pavia, Hon. Director, Tavi-tock Square Clinic. xii + 172 pages. 10s. 6d. net.

This attractively-written book includes some account of the various theories of sleep, and its therapeutic advice will be found valuable in treating all functional nerve cases.

THE PROGRESS OF LIFE
A STUDY IN PSYCHOGENETIC EVOLUTION

By ALEXANDER MEEK, D.Sc., Professor of Zoology in the University of Durham. viii + 193 pages. 10 Diagrams. 10s. 6d. net.

The inadequacy of the germ plasm theory as an explanation of evolutionary phenomena has led the author to indicate another explanation based on an "altogether" view of the cell and soma.

DISEASES OF WOMEN
NEW (FOURTH) EDITION

By TEN TEACHERS, under the direction of COMYNS BERKELEY, M.D., B.S., F.R.C.P., F.R.C.S. Fourth Edition, completely rewritten. xii + 558 pages, 8 Plates and 186 Illus. Price reduced to 18s. net.

Also by Ten Teachers: MIDWIFERY (3rd Edn.) 24s. net.

AN INTRODUCTION TO PHYSICAL ANTHROPOLOGY

By E. P. STIBBE, F.R.C.S., Department of Anthropology, University College, London. viii + 196 pages, 42 Diagrams. 12s. 6d. net.

This book provides the knowledge necessary for an intelligent grasp of recent theories and investigations concerning the ancestry of man.

WRITE FOR PROSPECTUSES.

GARROD, BATTEN & THURSFIELD'S

Diseases of Children

MICKLEFIELD IRRADIATED MILK

Treating the Cow.

By this process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

Full particulars appeared in an article in the LANCET, January 18th, 1930, p. 127, et seq., a reprint of which will be sent post free on request.

The milk is delivered every weekday in London; elsewhere by arrangement.

Write to J. O. HICKMAN, MICKLEFIELD GREEN, RICKMANSWORTH.

A RISK WHICH NEED NO LONGER BE RUN . . . .

PHILIPS "METALIX-PORTABLE"

enables any medical man to make excellent radiograms in his consulting room or in his patient's house.

He has no technique to master, there is no danger, and successful results are assured.

Literature or demonstration on request.

A car drives up to the patient's house. The doctor alights with two small packages and enters the sick room: in three minutes he has his "Metalix-Portable" ready for use—in another five he has made a visual examination and taken a radiogram.

But for the "Metalix-Portable" the patient must have been taken in an ambulance, at considerable risk, to the nearest X-ray installation.

These are facts that every medical man must face; science and enterprise have provided a new and wonderful aid to diagnosis which the progressive will adopt as they would an important new remedial measure.

PHILIPS

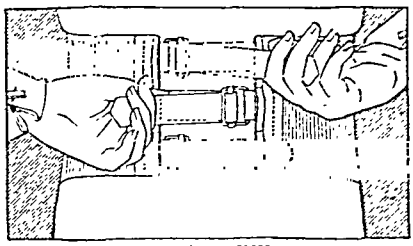
METALIX-PORTABLE

PHILIPS LAMPS LTD. (X-Ray Dept.), Philips House, 145, Charing Cross Rd., London, W.C.2.

THIS NEW *FLEXIBLE* SUPPORT

IS APPROVED BY LEADING SURGICAL OPINION

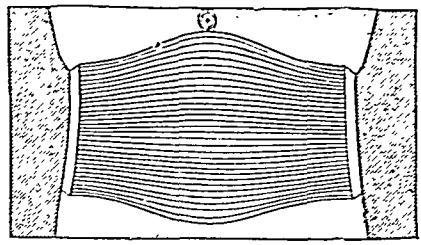
Brit. Pat. No. 279477.



Being Pliable, it Ex a Firm yet Natural Compression without Restriction

The Linia Belt represents a definite step forward in modern surgical belt construction, and its patented principles are widely approved by leading professional opinion.

This belt, designed by anatomical experts, is the result of 25 years' research and experiment in making elastic supports to medical requirements. The efficiency and comfort of this method of abdominal control is vouched for by the many prominent medical men who have adopted the Linia Belt for their personal use.



THE ACTION OF THE LINIA BELT

The Linia Belt, being made entirely in an exceptionally tough elastic tricot, with firm back and strong extendible front, gives the firm and efficient support so necessary for post-operation wear *without employing any rigid components.* Thus it allows complete freedom in movement and breathing. Corpulence is reduced by a gentle massage action and a *natural* compression exerted which restores any displaced muscles and organs to their natural conformation. Recommended for post-operation wear in cases of Intestinal Ptosis, Enteroptosis, Visceroptosis, Gastroptosis, Nephroptosis.

BACK VIEW.

The tough, live horizontal elastic of this special tricot can be regulated to the required tension by means of slide buckles. Thus its lifting and massaging powers are easily controlled. As the abdomen resumes its normal conformation, further adjustments of the slide buckles can be made.

FRONT VIEW.

At the front of the belt, the thin tricot of great strength can be extended to the required depth, so that a gentle pressure is exerted on the full area of the abdomen.

Pressure is applied from pubis to groins as a safeguard against rupture.

We invite you to submit this belt to your own tests

We shall be pleased to forward a Linia Belt for your inspection free of charge. *POST ORDERS* can be carried out to your direction on receipt of exact measurement round girth and required depth from pubis upwards. Standard depths, 9, 10, and 11 inches. *Prices:* Standard Model, 2½ guineas. In black, thread and elastic, 3 guineas; in pure silk and elastic, 6 guineas. Post free in United Kingdom.

The Linia Belt

Brit. Pat. No. 279477.

is on sale only at

J. ROUSSEL, 173, Regent Street, W.1 *(Special Branch for Men's Abdominal Belts)*

VERONIGEN

A liquid preparation of the Hypnotic Barbitone or Diethyl-barbituric acid has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, nor is cumulative in action, and in ordinary cases of insomnia, one fluid drachm of VERONIGEN is sufficient dose for an adult. As a preventive of post-operative vomiting, one to two fluid drachms of VERONIGEN may be given one and a half to two hours before general anæsthesia is produced, and as a result much less of the anæsthetic is required. As BARBITONE has a slight diuretic action, the mixture can be used when the heart is weak. Where sleeplessness is a concomitant of pain, rest and relief can frequently be obtained by the administration of one drachm of VERONIGEN and two drachms of ELIXIR ACID. ACETO-SALICYLIC (Hewlett's).

DOSE FOR ADULTS.—One fluid drachm diluted, one hour before going to bed.
For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN. Price 10/6 per lb. In 5, 10, 22, 40, and 90 oz. Bottles.

Introduced and Prepared only by C. J. HEWLETT & SON, LTD. Wholesale and Export Druggists

35-42, CHARLOTTE STREET, & 83-85, CURTAIN ROAD, LONDON, E.C.2.

Two fluid drachms contain **Beechwood Creosote 2m., Potassium Iodide 4 gr., Caffeine Sodio-Salicylate 1 gr., with Tinctures of Aspidosperma, Bryony and Cereus.**

Palatable and pleasantly flavoured.

Most useful and efficient for the relief of Lobar Pneumonia, Pulmonary Tuberculosis, Broncho-pulmonary Influenza, and Influenzal Laryngitis, particularly for controlling temperature and pleuritic effusion.

Price: 3/- per 8-oz. bottle; 16-oz. 5/6.

FULL LISTS ON APPLICATION.

The Ideal Laxative

REGULOL REGD.

"REGULOL" IS AVAILABLE IN TWO FORMS: "PLAIN" or "COMPOUND." The latter is a combination with Phenolphthalein 4 grains per oz., and is indicated in more acute forms of Constipation where the simple lubricating effect of Paraffin is insufficient.

CUXSON, GERRARD & Co., Ltd.

Oldbury. *Birmingham.*

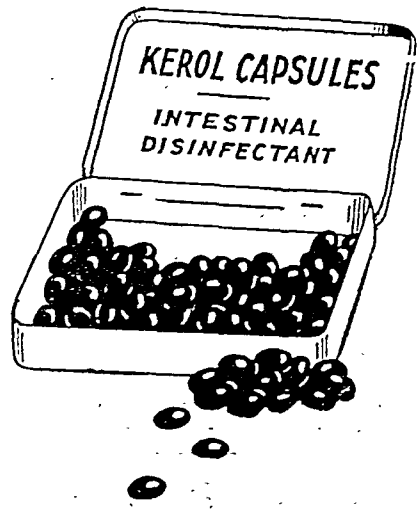
IT is a highly palatable Emulsion of Liquid Paraffin with Agar-Agar, possessing all the advantages of the former without its objectionable qualities, and forming probably the best possible remedy for Chronic Constipation in Children and Adults.

SAMPLE 1-lb. JAR FREE ON REQUEST.

Please indicate whether Plain or Compound is required.

(This offer is limited to the British Isles.)

ALIMENTARY TOXAEMIAS



IN our last advertisement, the subject of Alimentary Toxæmia was briefly discussed, and intestinal disinfection by means of Kerol Capsules was held to be the first line of treatment.

The reason for this may be stated as follows:—None of the ordinary so-called intestinal antiseptics, such as Salol and Beta Naphthol, are found experimentally to exert any disinfection of the contents of the bowel.

On the other hand, the high boiling hydroxyl compounds of the coal tar series are potent germicides, and, being unabsorbed, are non-toxic. They can therefore be administered freely without harm, and are found to prevent the multiplication of the toxæmic intestinal bacteria and to reduce them considerably

The active principle of Kerol is a complex mixture of these compounds. The administration of two 3-minim capsules thrice daily after meals has been repeatedly shown to reduce the coli content of the stools of individuals taking them by 99 per cent.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Kerol Capsules

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

DINNEFORD & Co. LTD.

IODINE THERAPY

IODOLAIT

(DUNCAN)

A palatable, pleasantly flavoured preparation containing an Iodo-protein compound equivalent to 2 grains of Iodine in each ounce.

Duncan

It is well tolerated, and, as it contains no Alkali Iodides, it is less liable to give rise to symptoms of Iodism.

Indicated in Arthritis, Chronic Gout, etc.

Sample and price on application.

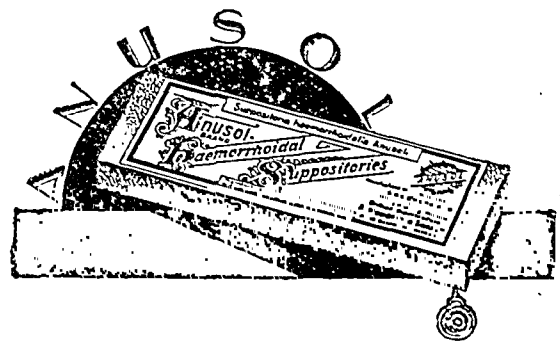
PLEASANTER FOR PATIENT—

MORE CONVENIENT FOR YOU—

For internal examination, manual or instrumental, K-Y Jelly gives the freest lubrication. It flows readily, cannot bind, and is quickly and conveniently squeezed out of its tube in exactly the quantity required. It does not soil clothing and is easily removed from hands or instruments by rinsing them in water.

K-Y Jelly is a blend of certain vegetable substances with carefully balanced proportions of boric acid, and does not interfere with the application of local remedies.

Physicians and Surgeons are invited to write for samples to *Dept. B*, Johnson & Johnson (Gt. Britain) Ltd., Slough, Bucks, stating the name of their local supply house.



* * *

K-Y Lubricating Jelly is obtainable from medical supply houses and pharmacists throughout the world. Tubes in cartons, 1/3 (Hospital size, 2/6).

PITUITARY
(Posterior Lobe)
EXTRACT
B.D.H.

It is particularly important that a product of the nature of pituitary extract, which is employed so often in emergency cases, should be dependable. From recent investigations *(Lancet,* March 8th, 1930, p. 522), however, it has been established that the proportions of the active principles vary considerably in different samples.

This significant fact makes circumspection in the choice of a brand of pituitary extract a vital matter.

Pituitary (Posterior Lobe) Extract B.D.H. is doubly standardised—for pressor effect and for oxytocic power—and every batch is guaranteed to be of uniform potency.

A GUARANTEED GUIDE.

By Our Analytical Experts.

No. 16.—ROBOLEINE.

HAVING heard a good deal of the virtues of Roboleine as a good "body-builder" in cases of malnutrition, we selected a sample of this food for analysis by our experts this week, as we desired to know whether it was really as good as it was reported to be. The result has proved that its makers, Oppenheimer, Son and Co., Ltd., are justified in claiming that it contains all the vitamins at present known to medical science, and that it is an excellent digestive food. The sample analysed was found to contain the following:—

	Per cent.
Moisture	23 28
Fatty matter	4 04
Mineral matter	1 72
Phosphate as P_2O_5	0 78
Nitrogen	0 06
Equal to protein (Factor 6.38) ..	0 38
Maltose	52.00

Lecithins and citralis were also present.

Roboleine is no new product. It has been in use for fully a generation, and proved itself valuable over and over again in cases of debility, loss of weight, malnutrition, sleeplessness, and especially so in tuberculous conditions. Nursing mothers have found both the quantity and quality of their milk improved by taking it, and for artificially fed babies it makes a useful adjunct in the diet. Full directions as to dosage are issued with each bottle, and nurses may feel quite safe in taking it themselves when feeling a little run-down, or in recommending a course of it to the convalescent patient just leaving their care. After influenza, typhoid fever, or any wasting condition, Roboleine should be taken regularly for three or four weeks while strength is returning.

The extract given shows the result of an independent analysis on a sample of **ROBOLEINE** purchased in the open market and made by the expert analysts advising a leading professional journal. The report shows that **ROBOLEINE** contains all the vitamins, and it confirms all the claims made for **ROBOLEINE** by the manufacturers, both as a body-builder and an anti-infective.

The Food that builds the Body.

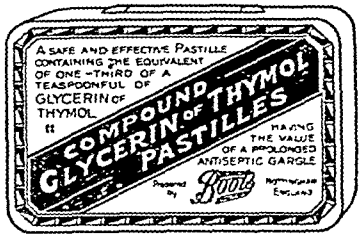
DIET IN INDIA

The following striking tribute to the Therapeutic Value of Dimol will appeal to all Medical Practitioners in the East.

"On arrival in this country one commits indiscretions in the way of fruit-eating, cold bathing, etc.

"In a very short time, and for a whole year, I was troubled with recurrent non-amoebic dysenteries lasting about a fortnight at each attack, in spite of diet, bismuth, pulv. cret. arom. c opio, acid sulph. and kaolin. The short intervals between attacks were also periods of dieting . . . and I had to adopt cholera belts even in hot weather. Cold bathing was taboo.

"I should like to say how grateful I am personally to Dimol; I certainly would not be without it now. It can be relied upon to abort an attack and to limit the period of diet to one or two days. I can now eat forbidden fruits (melons, etc.) ad. lib., discard cholera belts, and enjoy an hour's swimming daily.



"This is my third hot weather, and I have had only one month on the hills."

——, M.B., Ch.B.(Ed.).

After long and thorough investigation at the Royal Naval College, Greenwich, Dimol pulverettes are now supplied by the Admiralty for use in His Majesty's Ships and Royal Naval Hospitals. The Commonwealth Naval Board has also decided to include Dimol tablets in the Admiralty Scale of Medicines for use in the Royal Australian Navy.

Samples and Literature will be sent on application to the

ALOCOL

Colloidal Hydroxide of Aluminium

THE increasing prevalence of gastric ulcer and hyperchlorhydria has produced an advance in the treatment of these diseases.

"Alocol" (Colloidal Hydroxide of Aluminium) provides an antacid medicament far superior to subnitrate of bismuth, bicarbonate of soda and other alkalis. These merely afford a certain degree of ease, without bringing about a permanent relief of the condition.

"Alocol" absorbs the excess of hydrochloric acid without interfering with the normal antiputrefactive function of the gastric juice or harmfully affecting the processes of nutrition.

"Alocol" has been subject to extensive clinical trial, and literature giving full particulars of the results will be gladly sent to medical men on request.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

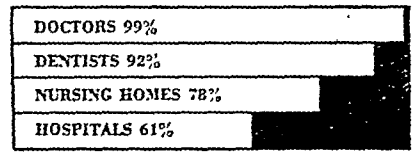
Assimilation is easy — EFFORTLESS

When solid foods cannot be taken, these Essences quickly stimulate

DURING severe illnesses — pneumonia, gastric disorders, and extreme prostration — there is so often vital need for a food which can be rapidly assimilated without any strain on the digestive organs.

In emergencies of this kind, doctors today find Brand's Essence indispensable. A recent investigation revealed that as many as 99 *out of every* 100 interviewed recommended this product to their patients.



For Brand's Essences contain all those invaluable constituents of meat which promote the flow of the gastric juices and make digestion easier.

Consisting only of the pure essences of the finest fresh meats conserved in their natural form, they can be rapidly absorbed without the slightest strain on the digestion. No substances are added which would prevent easy assimilation — such as colouring matter, gelatine, or preservatives.

During that period in serious illness when a patient's vitality is at its lowest, these Essences never fail to restore energy quickly and easily. And in convalescence, when the very idea of food is repugnant, Brand's Essences bring back the appetite — prepare the patient for more solid food.

In common with other modern doctors, you need have no hesitation in recommending Brand's Essences to your patients. They are obtainable at chemists and stores throughout the world in tins and glasses. Samples will be sent you gladly on receipt of a professional card. Write Dept. F5. Brand & Co. Ltd., Mayfair Works, Vauxhall, London, S.W.8.

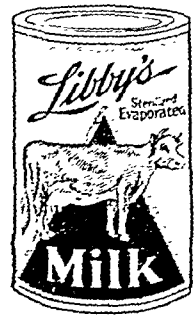
For the BABIES—

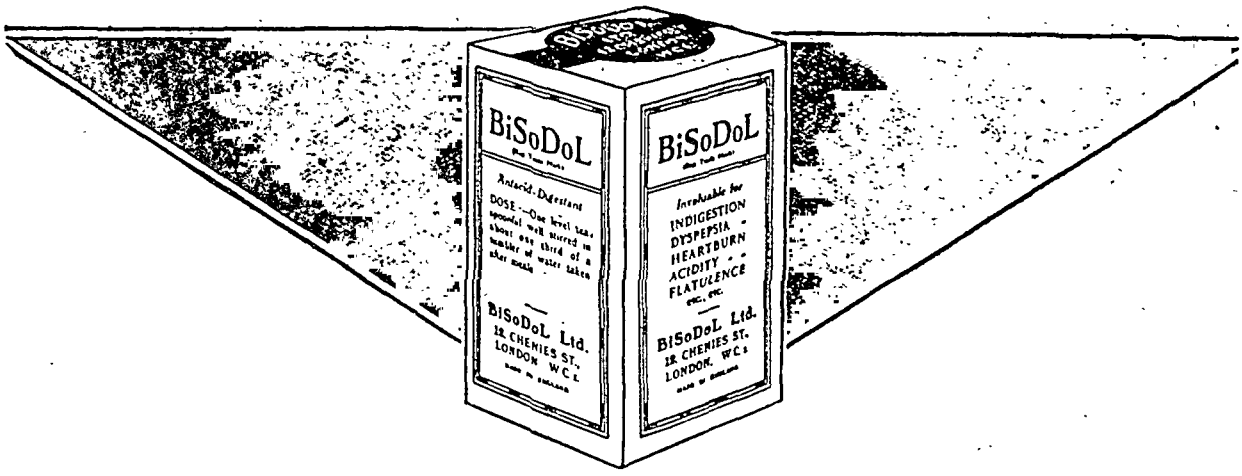


Clean-Pure-Milk as Easily Digested as Mother's Milk...

The process of sterilization absolutely destroys anything that could impair the freshness of Libby's Evaporated Milk. The sealed container provides adequate protection—it makes the milk as safe as if germs and bacteria did not exist. Sterilization gives protection—homogenization breaks up the fat globules into tiny particles and, therefore, makes the fat as readily assimilable as the fat of mother's milk. No matter what formula you may be using as a modification of milk, Libby's Milk is the ideal base from which you can start.

The whole day's feeding can be prepared at once and will keep fresh and sweet.

Libby's Evaporated Milk



£1,000 will be paid to any Hospital or other public charity if it can be proved that the claims made for Libby's Milk are not in accordance with scientific facts.

The Alkalies in Respiratory Diseases

Recent work on influenza, the common cold, pneumonia, and catarrhal fevers in general, has served to focus attention on the value of the alkalies in the treatment of these infections. It has been found that a system saturated with alkalies increases the resistance to bacteria. During the influenza epidemic of 1918, patients so alkalinised showed a low mortality rate and, in the main, a quick convalescence.

BiSoDoL, a balanced alkalinising agent, may be effectively employed to combat acidosis and build up the alkali reserve without upsetting the stomach or causing alkalosis.

The utility of BiSoDol as an antacid in hyperchlorhydria, gastritis, gastric and duodenal ulcer, has been abundantly demonstrated. It has also been given with marked success for the control of cyclic vomiting and the morning sickness of pregnancy.

BiSoDoL

Samples will be gladly sent to Physicians on request.

Milk Intolerance.

For many years Benger's Food, as is well known, has been used by practitioners throughout the world as a routine diet in all gastric cases, debility, and in cases of milk intolerance. The reason for this may be briefly stated:—

Benger's Food is a special wheaten flour preparation containing, in suitable amount, the two natural digestive principles — Amylopsin and Trypsin — in a latent state.

It is devised and expressly intended to be used in conjunction with fresh cows' milk, or diluted milk, if desired.

The two enzymes are in such condition as to exert their digestive powers under the condition which obtains during the preparation for use.

The Amylopsin acts on the carbohydrates (Starch) of the Food and gradually changes it into soluble sugars (Dextrins and Maltose mainly, with a little Dextrose) more or less according to the length of time allowed for digestion.

The Trypsin acts on the gluten of the flour and on the proteins (Casein, etc.) of the milk so that the curd which forms is softened, and as a result it separates in the stomach in fine readily-digestible flocculi instead of large, often indigestible curds. The extent of digestion can be varied; *it is important to note that complete pre-digestion can never take place.*

Benger's Food contains no preservatives. It is palatable and is free from rough irritant particles.

These considerations show that Benger's Food is not merely a mechanical milk modifier — it is a real modifier of a peculiar character.

THE "LANCET"
describes it as "Mr. Benger's admirable preparation."

A Physician's sample will be sent post free to any member of the Medical Profession making application to the Proprietors:—

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2$ Ca.

Unique Advantages:

1.—It is effective. It supplies the physiologically active calcium ion.

2.—It shows distinct superiority in all modes of administration.

ORALLY: It is well absorbed. It is easily administered and does not upset the digestive tract.

INTRAVENOUSLY: It is better tolerated than calcium chloride. The acid-base factor is eliminated.

INTRAMUSCULARLY: It is painless and non-irritating. It is the only calcium salt which can be so administered in adequate doses.

3.—It enables physicians to adequately meet the requirements of any given case.

BY VEIN, for acute need.
BY MUSCLE, to secure intense and prolonged action.
BY MOUTH, for prolonged administration, to meet an increased demand by the organism.

4.—It is completely sufficient in itself as a therapeutic agent.

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection.
5 c.c. size: Boxes of 2 and 10 ampoules.
10 c.c. size: Boxes of 1, 5, and 20 ampoules.

Powder for oral administration.—Cartons of 2, 4, and 16 ounces.

Tablets for oral administration.—Each tablet contains 25 grains of calcium gluconate and is especially adapted for division into three parts. Boxes of 30 and 150 tablets. Cartons containing 12 boxes of 30 tablets.

The Ingleby Lecture

ON

THE BLOOD TRAIL.

DELIVERED AT THE UNIVERSITY OF BIRMINGHAM, MAY 22ND, 1930,

BY

SIR JOHN BLAND-SUTTON, BT., LL.D.

WHEN men and women are impatient in relation to the discovery of causes and means for the cure of dangerous diseases it is useful to remind them of the Blood Trail as a remedy for their impatience.

Knowledge of the blood and its circulation has been acquired by slow and uncertain stages. Our interest in it begins in childhood. The colour and clotting of blood when it escapes from a living animal are among earliest experiences of what was called Animal Œconomy.

It is 300 years since Harvey discovered the circulation of the blood by observation and inference. Malpighi, at Bologna (1661), discovered the capillaries which link up the arterial and venous systems. He also saw the globules now familiar as red corpuscles. Leeuwenhoek (1673) with a simple lens saw the circulating blood in the tail of a tadpole and the web of a frog's foot. An astute observer—John Hunter—expressed this opinion in regard to the globules: The early observers probably imagined more than they saw because they used magnifying glasses!

One hundred years ago there were men who believed the earth to be flat: and there was much argument concerning the red corpuscles of the blood—were they globules or flat discs? In 1827 J. J. Lister, a wine merchant interested in optics, improved the compound lens and enabled observers to determine with certainty that the red corpuscles are circular biconcave discs. In 1862 Hoppe (Hoppe-Seyler) detected the haemoglobin of the red corpuscles. Sir George Stokes, two years later with the aid of a spectroscope, discovered the astonishing part played by haemoglobin in respiration. To-day, even with new *methods of research, it is not known how long a red* corpuscle lives fetching and carrying oxygen.

An expert—Dr. W. E. Cooke—recently describing in great detail the structure of the human erythrocyte, expresses the opinion that a volume could be written on its peculiar nature and character.[1]

Leucocytes.

The white corpuscles—leucocytes—were discovered by Hewson (1774). Seventy years later Wharton Jones detected their amœboid movements (1846). Their curious power of flowing through the walls of the capillaries without breach—diapedesis—was observed by Cohnheim (1867).

In 1883 leucocytes came prominently into notice, in consequence of the dramatic discovery by the Russian biologist Metchnikoff that they had the power of ingesting and digesting *organic particles in the blood, especially* microbes. Metchnikoff died in 1916. His Life, written by his wife, contains an account of the simple way in which the Phagocyte Theory was born. Metchnikoff was at Messina in 1882, and had been watching the mobile cells in the body of a transparent starfish larva, and the idea occurred to him that similar cells might serve in the defence of the organism against intruders. To test this idea he took some thorns from a rose tree and introduced them at night under the skin of some beautiful starfish larvæ: these larvæ are as transparent as water. *In the* course of the thorns were surrounded by mobile cells, as is to be observed in a man who runs a splinter in his finger. This simple experiment laid the foundation of Phagocytosis, to which Metchnikoff devoted twenty-five years of his life.

The Clotting of Blood.

Although coagulation of blood has been studied from early times and keen physiologists have given it attention, no one has found a satisfactory answer to the question: Why does blood clot when it leaves the body of an animal?

There is an aspect of it which concerns surgeons deeply—blood sometimes clots in blood vessels, especially veins, during life, and leads not infrequently to such a disaster as sudden death. Clotting of blood in veins during life has been recognized for centuries, and it is associated with the *condition called phlebitis—simply, inflammation of a vein.* Physicians, when making examination of the bodies of persons who died suddenly, occasionally found a large blood clot firmly plugging the pulmonary artery. In the middle of the nineteenth century it occurred to an observer that the fatal clot was not formed in the artery where it was found after death, but in some remote vessel, and becoming loose was *conveyed by the blood stream to the pulmonary* artery, which it plugged so completely as to cause death in a few minutes. A clot of this kind is sometimes rammed in the vessel as tightly as a pellet in a popgun!

It was Virchow who opened our eyes to such sequences and made physicians and surgeons realize their intellectual blindness.

When a mere boy I read in a medical journal (which I casually found among a parcel of stale papers) a lecture with a strange title—Thrombosis and Embolism. These odd Greek words attracted my attention; in plain English the title may be rendered "Clots thrown from a distance."

Ten years later, when making a post-mortem examination, that lecture came forcibly to my mind. I read with vivid interest Virchow's writings on Thrombosis and Embolism, which was deepened when I began to remove the uterus for fibroids, and came face to face with the part played by sepsis in causing coagulation of blood in the living body. Blood may be regarded as a fluid tissue, of which the plasma is the matrix, erythrocytes and leucocytes the cell elements. This question must occur to many: Why does blood remain fluid in the vessels of *living* animals? It remains unanswered.

Obstetricians and gynaecologists are specially concerned with thrombosis because blood is very apt to clot in the *big pelvic veins of lying-in women, and of men and women* who have been subject to operations on the pelvic organs. In such conditions the iliac, ovarian, and spermatic veins are liable to become reservoirs of blood clot: an entire clot, or a fragment, may be detached and swept by the blood current to the heart. Embolic clots are forcibly ejected into the pulmonary artery, and, when big, plug this vessel and kill the patient.

Post-operative pulmonary embolism occurring as a sequel to abdominal hysterectomy caused me grave concern. When I began to perform abdominal operations I soon realized that the peritoneum would not tolerate carbolic acid, neither in solution nor as a spray. When I restricted antiseptic treatment to the patient's skin and mucous membrane, my operative results immediately improved. *The mortality after hysterectomy for fibroids* fell to 1 per cent. This 1 per cent. was due to pulmonary embolism.

Gradually gynaecologists realized that post-operative embolism very rarely happened after *vaginal* hysterectomy. It is now admitted that post-operative thrombosis of blood in the iliac veins is a sequel of infection of the abdominal wound. The channels of infection are the deep epigastric veins; the iliac veins serve as reservoirs for the big clots which plug the pulmonary artery and lead to surgical tragedies. For example, a stout midwife had a large fibroid which I easily removed, and I secured the abdominal incision with thicker sutures than usual in order to obtain a sound scar in view of her occupation. On the eighth day after operation, at the usual ward visit I noticed that her temperature had suddenly risen to 103°, and said to the house-surgeon: "This forebodes thrombosis of the iliac veins. Pulmonary embolism is impending." *She died suddenly a few hours after the visit.*

I gave instructions for the pulmonary vessels to be carefully examined. The pathologist, knowing my interest in the matter, removed the thoracic organs entire. We examined them and found a *big embolus* plugging the pulmonary artery like a cork. It furnished an abundant growth of the colon bacillus.

In addition to big clots which plug with immediately fatal effect, there are smaller clots which readily traverse the large pulmonary arteries and become arrested in small vessels near the periphery of the lungs. Embolic clots of this kind are troublesome and retard convalescence. Pathologists remind us that every clot found in a pulmonary artery is not embolic. The clot may have been formed

in situ. This is true, and does not disturb the fact that venous blood is more prone to thrombose than arterial blood. *The blood in the pulmonary artery is venous in character.*

Facts accumulated since 1900 make it clear that the naked hands of surgeons are the chief infecting agents which patients risk when they submit to operations; this indictment includes midwifery manipulations.

The chief cause of post-operative thrombosis and embolism is sepsis, and its incidence has diminished enormously since surgeons adopted the habit of wearing sterilized rubber gloves when operating.

Cysts and Menstruating Tumours.

Menstruation—the rhythmical uterine bleeding of women—heralds the attainment of sexual maturity, and occurs monthly in healthy women. The cause, significance, and utility of menstruation are obscure; the blood is furnished by the peculiar tissue of the uterus known as the endometrium. Menstruation is dominated by the ovaries; and their artificial removal is followed by sterility and enduring amenorrhœa.

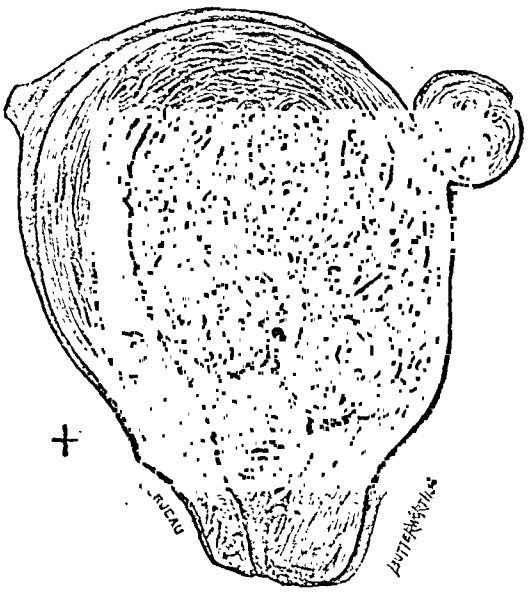

FIG. 1.—Uterus in section with a large patch of adenomyoma on its posterior wall. The new growth has permeated the peritoneal surface of the uterus. (From *Tumours.*)

Menstruation is not confined to human beings. I was astonished to discover its occurrence in macaque monkeys and baboons living in the Zoological Gardens, London; and was able to study this curious process on fresh material, but failed to discover the cause. It was suggested that menstruation happens in monkeys living in the Gardens because they are in a country and climate foreign to them. My observations were communicated to the British Gynaecological Society in 1886. In consequence of these observations W. Heape of Cambridge went to Calcutta for the purpose of studying menstruation in the sacred monkey of India—the Entellus monkey—and described his research in an elaborate paper in the *Transactions of the Royal Society* (1894). Heape's observations bear out in the main my conclusions, but the cause of menstruation remains obscure. The dominant features are these: menstrual blood is furnished by the endometrium; the superficial layer of epithelium is shed during the process; the shedding extends from the uterine orifice of the Fallopian tubes to the internal orifice of the cervical canal.

The ovaries are often occupied by cysts; many are ripening follicles and others are degenerate corpora lutea. It is not uncommon for an ovary to be converted into a cluster of cysts. Distorted ovaries of this kind are familiar to gynaecologists, and it is not uncommon to find them adherent to the body of the uterus, especially its posterior surface. In the course of operations undertaken for their removal the detachment of such cysts is apt to burst them, and they discharge thick blood resembling chocolate or tar; hence the term "tarry cysts" of the ovary. As a rule, both ovaries are affected, and this cystic condition is often associated with adenomyoma of the uterus.

Adenomyoma of the Uterus.

This tumour disease is the product of overgrowth of the endometrium with a responsive increase of the connective tissue in which the uterine glands are implanted. The increase of the endometrium leads to a corresponding enlargement of the uterus, and in clinical features it resembles a submucous fibroid. Operations are usually performed for an enlarged uterus of this kind under the impression that it contains a fibroid, but after removal its nature is easily appreciated on bisecting the mass, for it is unencapsuled and displays an intimate association with the wall of the uterus (Fig. 1). Occasionally buds of the endometrium appear on the peritoneal aspect of the uterus which to the naked eye resemble subserous fibroids, but on microscopic examination they will be found to contain diffuse tissue resembling the endometrium, and they lack a capsule. In typical examples the appearance of the cut surface of a large adenomatous mass resembles the fabric known as "watered silk." In some examples of this disease the uterus may be as big as a coco-nut and clinically mistaken for a submucous fibroid.

FIG. 2.—Microscopic features of diffuse adenomyoma of the uterus. (From *Tumours.*)

The Endometrium—the Organ of Menstruation.

For the proper understanding of the nature of the endometrium it is necessary to bear in mind that the uterus is a hollow muscular organ in which the embryo is nourished and protected from the time it leaves the Fallopian tube until it is fit to be expelled as an air-breathing child.

Until the advent of puberty—declared by the onset of menstruation—the cavity of the uterus is lined with endometrium which is covered with columnar epithelium, and beset with glands which discharge their secretion into the central cleft. The endometrium and the muscular wall of the uterus insensibly blend.

It is common knowledge that the menstrual fluid—mainly blood—is furnished by the endometrium, and this is the essential organ of menstruation. The blood is effused at intervals of four weeks, mixed with shed epithelium. Occasionally the epithelium is shed as a complete cast—menstrual decidua.

It is established that the tissues of tumours are derived from the normal tissues of the body. Tumours do not differ in their habits (ecology) from normal tissues; this is demonstrated in a curious way by tarry cysts of the ovary. In 1920 J. A. Sampson, an American gynaecologist, discovered that the lining membrane of such cysts is structurally identical with endometrium, and the blood they contain is furnished by it. These cysts actually menstruate!

How do they acquire an endometrium? Sampson explains it in this way: During menstruation blood and shed epithelium escape from the uterine cavity into the Fallopian tubes; leaking from the ostia into the pelvic cavity this fluid comes in contact with the surface of the ovary, the cells engraft themselves on the ovary, flourish, multiply and originate an endometrial cyst! I venture to suggest another explanation: Tarry cysts of the ovary are associated with adenomyomatous uteri. In this disease

epithelium is apt to permeate the wall of the uterus and bud-like outgrowths may emerge on its peritoneal surface.

When an ovary lies in contact with an adenomyomatous uterus its tissues may be implicated by the active epithelium and in this way establish a menstruating cyst. An example of such implication is represented in Fig. 3: in this instance the uterine wall is occupied by a localized patch of adenomyoma situated near the tubal angle; to the naked eye it appeared to be an intramural myoma, but unencapsuled. This raised my suspicions, and a microscopic examination proved it to be a localized patch of adenomyoma. The adherent ovary was cystic and the cavities of the cysts contained tarry blood; the endometrium they contained was derived from the uterine endometrium by *permeation*.

Although unconvinced by the theory of implantation secondary to retrograde menstruation I was unable to discard it in the face of the following facts.

A woman, aged 29, complaining of dysmenorrhœa, was submitted to the following operation by Bonney. The uterus was withdrawn from the pelvis through a median subumbilical incision,

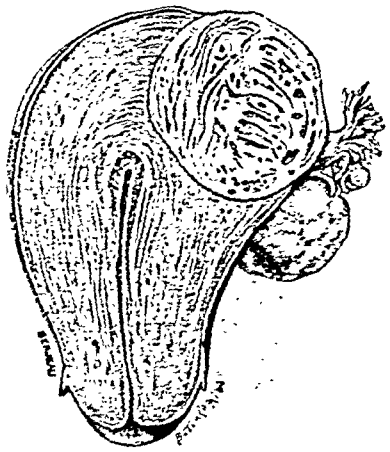

FIG. 3.—Uterus in section with a patch of adenomyoma and a cystic ovary. From a primipara aged 35. (*Tumours.*)

its cavity exposed and the endometrium thoroughly erased. During the operation the margins of the abdominal incision were soiled by blood and endometrial fragments. Two years later the patient returned with a small lump at the lower end of the abdominal scar. This lump swelled during a menstrual period and became painful: it was excised and on microscopic examination displayed the structure characteristic of normal endometrium; there was blood in the stroma and in the lumen of the glands.

This experience has the value of a reliable experiment. The adventitious vascular lump arose in a fragment erased from the endometrium and accidentally implanted on the raw margin of the abdominal incision made two years previously.

The Endometrium and the Mammary Gland: A Comparison.

The endometrium is liable to the same perversions as a compound secreting gland—for example, the mammary gland—with which its functions are closely correlated in reproduction.

When the functions of the menstrual organs are manifest the mammary glands are quiescent, though they may exhibit what is sometimes poetically called sympathy with them in activity. When the endometrium—so far as menstruation is concerned—is in abeyance—for example, during pregnancy—the mammary glands are active, and when the uterus acquits itself normally their activity is manifest.

The correlation of the breasts and endometrium is obvious in a comparison of their pathological tendencies. The essential gland elements of each are liable to similar morbid changes—adenomas, papillomas, and polypi. The liability of the mammary gland to cancer is perhaps greater than that of the endometrium. This may be due to exceptional facility of observation in the case of the breast. The very rare cystic adenomas of the breast are parallel to the large adenomyomas of the uterus.

Cancer of the endometrium differs clinically and pathologically from cancer of its neck, and, like mammary cancer, leads to secondary deposits in the lungs.

The leading clinical features of adenomyoma of the uterus are excessive and prolonged menstruation associated with enlargement of the uterus, which simulates the physical signs presented by a submucous fibroid. The tendency of adenomyomatous tissue to permeate adjacent organs explains its occurrence in the round ligaments of the uterus and the wall of the rectum. In patients under my own observation large adenomyomas were accompanied by excessive and *prolonged* menorrhagia and its sequence—profound anæmia.

The results of subtotal hysterectomy for this disease are admirable. The patients are usually nulliparous—spinsters and barren married women between 30 and 50 years of age.

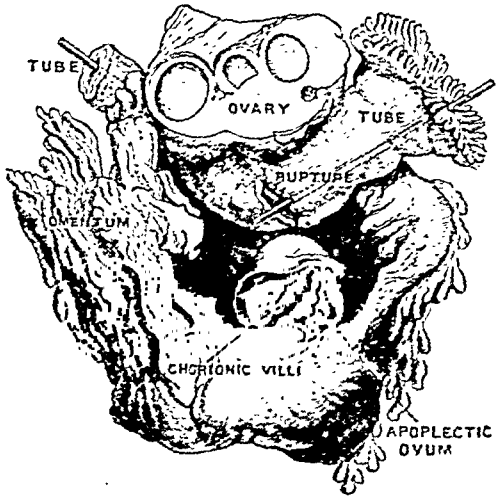

FIG. 4.—Ovary, Fallopian tube, and a fold of omentum, lying in the omental fold—a mole or apoplectic ovum which was discharged through the rent in the tube. Removed by operation in 1886.

An accurate diagnosis is only possible after removal of the uterus.

Note.—Mr. F. Roques lent me some excellent slides obtained from endometriomas, which have been useful in the preparation of this lecture.

Pelvic Hæmatocele.

Fifty years ago textbooks on diseases peculiar to women contained descriptions of disabling, and occasionally fatal, *effusions of blood in the pelvis* which occurred in healthy women in the prime of life. Such collections, when the blood was free in the pelvic cavity, were called intrapelvic hæmatoceles. When the blood was effused between the layers of the broad ligaments of the uterus it was called a hæmatoma. Various causes were suggested to account for such effusions. Occasionally they were profuse and caused death. Nothing was known of the cause.

Lawson Tait simplified our knowledge of these things. When operating on women for the relief of chronic disease of the ovaries and Fallopian tubes he occasionally found an *abundant collection of fresh blood* in the pelvis. His experience led him to announce this bold *generalization*. *Probably all forms of ectopic pregnancy have their starting place in the Fallopian tube.*

Tait produced no evidence to support his opinion. I was impressed with the brilliant conception and looked out for a sign. It came in an unexpected way.

While the Imlach trial was in progress (1886) I operated on a young and recently married woman at the Middlesex Hospital. The patient had been admitted under the care of the obstetric physician (in those days obstetricians did not perform abdominal operations); the pelvic cavity was flooded with blood, and in a pouch of omentum, associated with a rent in the Fallopian tube, lodged an oval body the size of a chestnut. I removed the tube, ovary, and

fold of omentum with the oval body in one piece, and preserved them for future study.

Three years later (1889) a woman was admitted under my care in the Middlesex Hospital with signs of intra-pelvic bleeding. I promptly operated, and found a movable body as big as a walnut with a smooth cavity at one pole, and at once recognized its similarity to the familiar uterine mole. The effused blood and clot were collected, and the operation completed. I then washed the clot in a glass vessel with a gentle stream of water from a tap. Suddenly I saw the head of an embryo rise to the surface in a gentle swirl. This clinched the evidence—I had found a *tubal mole*! The name soon became current in gynaecological literature.

When no embryo is forthcoming the presence of chorionic villi in the mole is now accepted as evidence of tubal gestation.

This lecture was opened with a recital of the Blood Trail. Let me end by reminding you that men who make original observations are often obdurate in accepting the discoveries of their contemporaries.

Harvey discovered the circulation of the blood, but did not believe in the existence of the lacteals described by Aselli (1622). The discovery of the lymphatic system was second only in importance to that of the circulation of the blood.

Baer found the human ovum, but would not accept the idea that the spermatozoon initiates development in the ovum. We may believe that the tail of the spermatozoon led to the discovery, "since things in motion sooner catch the eye than what not stirs."

Lawson Tait, in his vigorous Ingleby Lecture (1886) on Pelvic Haematocele, insisted that the blood came from the sac of an ectopic pregnancy. He not only ridiculed my discovery of the tubal mole, but warned teachers of midwifery against my transcendental notions relating to tubal abortion.

To-day a tubal mole is as familiar to a gynaecologist as a placenta to a midwife.

SPONTANEOUS DETACHMENT OF THE RETINA.

BY

ARTHUR W. ORMOND, C.B.E., F.R.C.S.,

OPHTHALMIC SURGEON AND LECTURER IN OPHTHALMOLOGY, GUY'S HOSPITAL.

As far as I have been able to ascertain no general account of Professor Gonin's work on the causation and treatment of spontaneous detachment of the retina has up to now appeared in English. His writings have been either in French or in German, and have been directed to explaining various aspects of his views, but there is no comprehensive article dealing with the matter. Having had the good fortune to see Professor Gonin operate, and to have his views explained to me personally, I think it may be of use to my colleagues and to the medical profession generally if I attempt to place on record what I understand to be the pathological conception on which he bases his mode of treatment.

By spontaneous detachment of the retina is meant the condition of retinal detachment found without evidence of any concomitant gross pathological condition, and excludes intraocular growths, definite inflammation, gross traumatism, etc., the detachment being unaccompanied by any of these factors and apparently having occurred *spontaneously without any obvious visible cause*. It is, however, generally allowed that some degree (not necessarily a high degree) of myopia may be present, or the condition may occur in old people where senile changes exist and without any traumatic history, or only a history of slight jarring, shaking, etc., of the eye or body.

Professor Gonin first visualizes a change in the vitreous, and subsequently in the retina, which may be unobservable to ordinary ophthalmoscopic examination. A partial liquefaction of the vitreous takes place, and a localized or general thinning of the retina, also giving no definite ophthalmoscopic evidence. The retinal change, however, is often in the region of the ora serrata, and therefore not obvious to ordinary ophthalmoscopic view unless extraordinary means are taken, such as full dilatation of the pupil and pressure deliberately made outside by the finger, *in the neighbourhood of the ciliary body*.

The primary change in the vitreous is one of partial liquefaction. The evidence for this is the frequent presence of fine floating opacities in myopic and senile eyes, and the occasional presence of a deformation of the details of the papilla, which vary with movements of the ophthalmoscope, presenting a condition similar to that seen when viewing the fundus through an irregularly astigmatic lens or cornea; in addition we can sometimes see a diffuse opacity in the vitreous associated with "floaters" or streaks, but it is allowed that the ophthalmoscopic evidence of a liquefied vitreous may pass unnoticed or give only very equivocal signs. With regard to the retina, Professor Gonin suggests that the retina, like the choroid, may be subject to strain and stress, and may be the subject of thinnings, atrophic areas, holes, and tears. The retina as well as the choroid is more firmly attached at one place than at another. The optic nerve fibres secure the retina firmly at the optic disc, but the attachment at the ora serrata is thinner, more attenuated, and more apt to fail, either as the result of pathological conditions affecting the choroid, or a senile condition associated with the attenuation of the nerve fibres and its parenchyma. On the other hand, the choroid is more firmly attached to the ciliary body and yields in the region of the optic disc and macula.

The partial detachment and retraction of the vitreous turns that body into a heterogeneous system, consisting of (1) non-albuminous watery fluid, and (2) the unaltered or only slightly altered vitreous gel. This condition has an importance, Professor Gonin thinks, in causing an unequal strain on the thinned and degenerated retina, so that any sharp abrupt movements of the eye or body may result in a sudden pull on the friable membrane. Traversing the liquefied vitreous may be strands of vitreous jelly attached at one point more or less firmly to the membrana limitans interna, and any abrupt sharp movement may cause a definite localized strain or pull at a point in the retina. The presence of any fine adhesion, the result of a small localized inflammation, would fasten the retina at such a point to the underlying choroid and would form an attachment which, as a result of even very slight trauma, would allow a tear to take place if the surrounding area were only supported by a liquid vitreous.

Professor Gonin believes that detachment of the retina only takes place if a tear or hole exists in the retina, and that this hole allows the liquid vitreous to pass through it and so raise the retina from its bed on the pigment epithelium. These retinal tears are usually situated, in recent cases, on the convexity of the detachment, but if and when the fluid shifts further round or down, then the tear may be found at a spot where the detachment has become less raised. Another area where the tears are often found is in the region of the ora serrata, because it is here that the retina is thinnest, most vulnerable, and liable to degenerative and pathological changes either from cystic degeneration or choroido-retinal atrophy. Holes in the area behind the equator are less common, and rarer often than not are the result of gross traumatism or definite pathological change.

Professor Gonin observes that in macroscopical specimens of spontaneous retinal detachment there is no gelatinous clot behind the retina—that is to say, no coagulable exudate the result of inflammation. The preretinal and subretinal spaces are filled with an identical fluid of a watery nature. The vitreous gel is retracted forward, and is best and most abundantly seen between the equator and the ora serrata, and shows more or less extensive adhesion with the retina. These macroscopical specimens frequently disclose the presence of a hole or tear.

A simple progressive stretching is not sufficient to detach the retina from the choroid, as was originally supposed to be the case in myopic detachment; on the contrary, the retina can adapt itself better than the choroid to a gradual enlargement of the globe; the retina yields only to a sudden tension, and is torn either at the

ora serrata or at some point where vitreous bands are adherent to the retina, a condition which is pathological: normally, the retina is not displaced even in complete liquefaction of the vitreous, unless some pathological cause has produced adhesions between the vitreous gel and the retina, and if a contusion occurs it results in a sudden abrupt pull on the thinned degenerated friable retina.

Professor Vogt writing recently in the *Klinische Monatsblätter für Augenheilkunde*, 1929, lxxxii, 619, says:

"It is rarely certain that *traumatic detachment* is caused by such a hole. Contusion produces a tear in the retina which is usually situated peripherally, since there the retina is thinnest and more or less lacks nerve fibres which act as support. Through this retinal perforation vitreous fluid soaks and detaches the retina from its base, the pigment epithelium. In the cases I saw, a vesicle was formed, on whose summit the perforation was situated. In the course of days and weeks the subretinal fluid increases, and larger portions of the retina are detached. Finally total *detachment* results.

"Systematic investigation of *spontaneous* detachments makes it probable that in them also such a tear or perforation is the cause of the detachment. In a large number of such recent cases one finds a perforation, a tear, exactly as in the traumatic type. Here also in the detachment which is only a few days old as yet it is placed upon a vesicle-like elevation, as in the traumatic type. Here also the detachment, originally *circumscribed*, is limited to the region of the tear. It would be denying simple facts to doubt the causal connexion between spontaneous detachment and perforation. I often found the retina in the neighbourhood of the perforation to be broken up into shreds and flakes, a sign that it is tearable and capable of little resistance.

"The weakness of the tissue is also seen in the fact that the retinal tear usually grows larger in the course of weeks or months and *occasionally new tears result. This increase is* probably caused by the swinging movements which the retina performs in the vitreous body during the movements of the globe of the eye and the body by reason of its greater specific gravity. One can, as you know, *control* these swinging movements ophthalmoscopically. I confirmed experimentally that the retina has a greater specific gravity than the vitreous body. Retinal fragments introduced into normal or liquefied vitreous fluid could be re-impregnated in it."

So much, then for the considerations which have led up to the treatment. Professor Gonin had reached these conclusions with regard to the cause of spontaneous detachment of the retina long before he applied them to the question of treatment. If it is the hole or tear, however produced, which is the fundamental cause of the detachment then if that hole can be closed the *status quo ante* ought to be obtained. Eventually he tried.

The operation is not difficult and carries no greater risk than is incurred by the time-honoured cauterization of the globe, which is done for the purpose of establishing drainage for the subretinal fluid and a possible anchoring of the retina to the choroid by the production of a contracting scar. But Gonin's whole point is that it is useless to attempt this cauterization anywhere save in the immediate proximity of the tear. The cauterization must involve the tear, the whole tear, and as far as possible only the tear, and effectively close the hole and "nail" the retina to the choroid by means of a contracting cicatrix. Much time and care must be exercised to locate the spot where the cautery is to enter. The operation is not applicable if the hole is in the region of the optic disc or macula. If the hole is large or multiple then more than one cauterization will probably be necessary, and if it cannot be reached by reason of its position in the eye then the case is not one for his operation. About 22 mm. from the corneo-scleral margin seems to be the practical limit of attempt and even such a point would be difficult to reach with precision.

Search long and diligent must be made to locate the hole, and until it is found it is useless to attempt the operation. When it has been found, it should be accurately localized and the meridian in which it lies marked by a definite technique, so that no hesitation occurs at the operation. The globe is divided for localizing purposes into various planes indicated according to a clock face: vertical, XII-VI; horizontal, III-IX; down and out, and down and in, II-VIII; IV-X, etc.

The meridian, being decided on, is indicated by two small points made at the corneo-scleral margin just under the conjunctiva by means of a pin dipped in Indian ink. Having fixed the meridian, the next point in the localization is to decide how far back the hole is from the ora serrata or from the most extreme point visible to the ophthalmoscope with fully dilated pupil and the eyeball rolled out to the extreme periphery. Professor Gonin has laid down certain figures for our assistance here, also a very explicit and practical paper has been written by Dr. Marc Amsler,[1] a clinical assistant of Professor Gonin's, which gives very useful suggestions for carrying out this task of localization:

"... la question que nous nous posons est celle-ci: combien de diamètres papillaires peut-on compter entre la *déchirure et l'ora*? En d'autres termes, combien de diamètres papillaires peut-on aligner au delà de la déchirure jusqu'à l'extrême limite visible du champ ophtalmoscopique?"

The diameter of the optic disc represents 1.5 mm., the distance from the ora serrata to the limbus is taken as 8 mm., so that if the tear appears to be 4 discs' breadth from the extreme periphery of the visible fundus, with the pupil widely dilated, the tear would be 8 + 6 mm. from the corneo-scleral margin = 14 mm.

Having found the tear, aligned the meridian, and measured the distance from the corneo-scleral margin along that line, and having marked externally on the limbus of the cornea two spots representing the meridian, the surgeon is in a position to decide if he can reach the spot indicated with his cautery. The operation is done under a local anaesthetic and the ordinary surgical technique is carried out.

Before operating Professor Gonin marks his meridian by passing a fine silk thread through the conjunctiva, immediately over the further spot of the two, thus marking the meridional alignment. This thread is knotted and drawn through just as a seamstress does when starting to sew, and is used to indicate the meridian, because, with the manipulation of the tissues, blood and fluid appear inevitably when the operation starts, and the mark previously quite obvious may become obscured; whereas the thread can always be found and made to connect the two spots indicating the meridian, so that the surgeon is never at a loss to recover his alignment during the operation should his marks become obscured. The thread is inserted on the inked spot furthest from the tear, and should eventually connect three points—namely, the two marked with Indian ink and the exact point at which the cautery is to enter the globe.

The sclerotic is laid bare over the area which has been found to correspond with the tear seen within the eye, and by means of callipers the distance from the corneo-scleral margin along the meridional line is measured to a fraction of a millimetre. This spot is marked by the pointed arm of the callipers being dipped in an alcohol solution of gentian violet, so as to mark definitely the exact spot which the surgeon, after prolonged care and calculation, has concluded represents the external point immediately over the hole in the retina. A Graefe's knife is now entered through this spot, the cutting edge of the knife being directed towards the cornea, and the depth to which it is inserted being dependent on the condition of the detachment; if subretinal fluid begins to flow out, the knife must have reached the space just external to the retina and the loss of some of the fluid may allow the retina to fall back nearer the sclera. The knife is withdrawn now, and if the operator inserts his glowing cautery he will produce a "sphere of influence" that is likely to involve the retina at the position of the tear. That this happens in some cases, probably in many, is now, I think, *definitely established*. The heat is sufficient to burn the margin of the sclera, the choroid, and to radiate through the intraocular fluid and inflame the retina. This cauterization produces an area of inflammation which in a few days' time—nine to twelve—causes a contracting scar which ultimately settles down after the inflammation has ceased. In this way it is certainly possible sometimes to close the hole, "nail" the retina to the choroid and sclera, and, if Professor Gonin's conclusions are correct, cure the detachment, the subretinal fluid being absorbed, provided that the communication with the vitreous chamber through the hole is completely closed.

SOME PRINCIPLES IN THE MODERN TREATMENT OF RHEUMATIC DISEASES.*

BY

W. S. C. COPEMAN, M.A., M.B., M.R.C.P.,

HONORARY PHYSICIAN, BRITISH RED CROSS CENTRAL CLINIC FOR RHEUMATIC DISEASES, REGENT'S PARK; REGISTRAR TO MEDICAL OUT-PATIENTS, ST. MARY'S HOSPITAL.

THE classification of the various forms of rheumatism generally met with varies in different countries—as does also the actual type of disease. This lack of uniformity in nomenclature is one of the causes of the slow progress in the study of this group of diseases up to the present time.

CLASSIFICATION OF RHEUMATIC DISEASES.

The following classification proposed by the British Ministry of Health in its report (J. Alison Glover, 1924) is now generally adopted.

GROUP A.

1. Rheumatic fever.
2. Subacute rheumatism.

GROUP B. Non-articular manifestations.

3. Muscular rheumatism (myalgia), including fibrositis, pleurodynia, and torticollis.
4. Lumbago; classified alone on account of its occupational interest.
5. Sciatica and brachial neuritis.

GROUP C. Chronic joint changes.

6. Rheumatoid arthritis (infective periarthritis).
7. Osteo-arthritis.
8. Gout, acute and chronic.
9. Chronic joint changes unclassifiable.

GROUP A.

With Group A I do not propose to deal, since both the etiology and the treatment tend to have separated this group clinically from the others to a very large extent.

GROUP B.

We must first briefly consider the etiology of non-articular rheumatism. When a muscle is at rest its reaction is alkaline, whereas when it contracts it gives out heat, and sarcolactic acid and succinic acid are produced. In the normal tissues these are quickly got rid of by oxidization with the production of CO_2. In order that this may occur, however, it is essential that these waste products of muscular activity should be removed in the shortest possible time from the site of their formation. If there is a block in the lymphatic drainage system these substances, accumulating locally, will become irritants, and the response of the tissues to irritation is inflammation. The results of this inflammation appear in the small nodules and thickened fibrous bands which are generally found in these conditions. These differ, however, from ordinary fibrous tissue in the fact that they can be massaged away.

Although in this group the bacteriological "focus of infection" is believed by many to be the underlying causative factor, no one has yet demonstrated any specific organism recoverable from the nodules. Infective foci, if found would naturally be dealt with in every case. The most efficient local forms of treatment in this group are hydrological and physical, particularly if sweating can be induced. The principles of these methods will be described in more detail later. Of other general methods, rest, avoidance of cold and constipation, and the adoption of a diet well balanced in both its chemical and vitamin content are the most important.

GROUP C.

The majority of rheumatic patients seen in out-patient departments come within this group, excluding those whose arthritis can be traced to some specific cause, such as tuberculosis, dysentery, gonorrhoea, or the pneumococcus. Many who originally come complaining of vague though distressing gastro-intestinal symptoms will be found to develop chronic joint changes ultimately. At St. Mary's Hospital I have traced the history of a certain number of sufferers with arthritis back for some two years; in about 70 per cent. the primary reason for seeking medical aid was either gastro-intestinal or a complaint of "giddiness." Little attention seems to have been paid to this association of chronic rheumatism with digestive disorders.

If we may omit the consideration of gout (since the literature on this subject is vast, and on the whole better known) we have left for consideration rheumatoid arthritis, osteo-arthritis, and "chronic joint changes unclassifiable."

The term "rheumatoid arthritis" is perhaps one of the most misused in the whole of medicine. It is now generally accepted to mean a disease commonest among, if not confined to, young women, particularly those who follow an indoor occupation, and characterized by a process of "atrophy"—rarefaction and softening of the articular ends of the bones which enter into the affected joints. When the muscles and tendons surrounding the joints retract, considerable deformity will result. In addition, there is usually a considerable wasting of the muscles themselves, and extensive involvement of the periarticular tissues. The joints most commonly affected at first are the smaller joints of the fingers, the metacarpo-phalangeal and wrist joints, and often the maxillary joints. The lesions appear gradually and tend to be symmetrical; they advance progressively and there is in most cases an accompanying secondary anaemia. The etiology is obscure. In the Ministry of Health's report the condition is assumed to have an infective origin, but we all see many cases in which no such origin could be assigned with justice. Infection accounts for the cases seen in male patients, together with a certain and possibly large proportion in the females; the remainder would appear to result from metabolic disturbances—probably from some "endocrine imbalance." This supposition is supported by the observations of Pemberton and Pringle and Miller on the lowered glucose tolerance found in these cases. The joint effusions are invariably sterile.

The preliminary treatment should be directed towards eliminating infection if present. The teeth should be *x*-rayed, and those radiologically and clinically "found wanting" should be removed. As much digestive disorder is probably caused by removing the teeth as there is arthritis cured by it; we may, however, bear in mind the adage that "uneasy lies the tooth that wears a crown." Damp and draughts should be excluded from workroom and dwelling houses. Since the patients generally have a lowered sugar tolerance, it is wise also to exclude excess of carbohydrates from their diet. Ray has pointed out that as most persons with rheumatoid arthritis have been forbidden to eat "red meat," they will have come to depend largely on the carbohydrates, and will need to be persuaded back towards the paths of protein, fat and adequate vitamin content (especially vitamin B). Bread, sugar, jam, pastry, and potatoes are best omitted.

Permanent deformity in this form of arthritis is more to be expected than in any other forms of arthritis. Early and effective splinting is therefore a *sine qua non* of treatment. The subsequent indications are mostly hydrological and physical, and will be dealt with separately. Lately I have investigated the therapeutic value of blood transfusion in rheumatoid arthritis, in certain cases with gratifying results that will shortly be published.

Osteo-arthritis is now considered to be entirely unrelated to rheumatoid arthritis, and the term "arthritis deformans," which formerly included them both, is becoming obsolete. The lesions in osteo-arthritis are primarily those of cartilage and bone, rather than of the periarticular tissues and joint capsule; the cartilage may, in fact, become entirely replaced by fibrous tissue. The trouble is generally confined to one or two of the larger joints such as the hips, shoulders, or knees; and constitutional disturbance is noticeably lacking, though the local joint pain may be severe—usually only on movement. The ends of the bones enlarge and osteophytes form round the edges of the articulations. Briefly, osteo-arthritis may be considered as a "hypertrophic" arthritis, and the rheumatoid form as an "atrophic" arthritis. The various forms of spondylitis generally described are all osteo-arthritic manifestations in the spine.

*A paper read to the Westminster and Holborn Division of the British Medical Association, March 18th, 1930. A cinematograph film illustrating some hydrological methods of treatment was shown (by courtesy of Mr. John Hatton of Bath).

Osteo-arthritis occurs considerably later in life than the rheumatoid and infective forms of arthritis; often in association with arterio-sclerosis, high blood pressure, and local trauma. The evidence on which an infective origin is assigned to this disease seems to me to be unconvincing. A metabolic disturbance, often in combination with slight persistent trauma, seems to be the effective cause in most cases.

The aims of treatment in this group must be to promote the elimination of those products of metabolism which tend at this time of life to be retained more than previously, and for this reason spa treatment is of very real benefit to this class of patient. The local treatment is mostly directed towards relieving pain and improving the functions of the skin and muscles by hydrotherapy and massage, and later by electrotherapy. Finally, if osteophyte formation proceeds apace, steps must be taken to ensure that the inevitable fixation of the joint occurs in a suitable position; orthopaedic measures, both operative and instrumental, may have to be undertaken. It is also very important to deal with any undue increase of body weight, particularly in the so-called "climacteric arthritis," which is generally included under this heading.

Principles of Treatment.

So many therapeutic methods are advocated for use in the rheumatic diseases that it may be profitable to consider those that are most usually employed, and to try to correlate their underlying principles.

Removal of Infective Foci.

The subject of the colon as a source of sepsis is not so simple as was at one time imagined. Most normal persons can, according to Cruickshank, produce a copious growth of streptococci from their stools by the expedient of taking a mild purgative or a carbohydrate diet. One of two main types of bacterial action may obtain in the bowel, the fermentative or the putrefactive, the occurrence of either depending largely on the diet, and being capable of alteration by this means, or by implantation of the *Bacillus acidophilus*: such alteration is sometimes of considerable therapeutic benefit to the patient, even in the absence of definite colitis. Though but little is known of the degree to which retention of faecal contents may influence the arthritic process, experience teaches that it is often wise and beneficial, in the presence of stasis, to aid in their elimination, whether it be by purgation or colonic lavage, or treatment at a spa possessing sulphur or purgative waters.

Vaccines.

Vaccine therapy in arthritis has been, on the whole, disappointing. How far this should be considered to be due to incorrect selection of cases and organisms, and how far to incorrect expectations of the results likely to accrue, is a matter which it is difficult to judge. That in certain cases the results may exceed our expectations is a matter of experience. It is perhaps not sufficiently realized that even if a focus of sepsis is found, it is not of necessity the only existing focus, or the focus causing the arthritis; and to expect a vaccine to restore function to a contractured or ankylosed joint, as many appear to do, is absurd.

Non-specific Protein Therapy.

For some years the injection of T.A.B. vaccine, milk, or other proteins has been advocated in the treatment of arthritis, the rationale being that a high degree of leucocytosis is thereby achieved. Good clinical results are said to occur, but they tend to be of a temporary nature. It has been suggested that it is by reason of their protein content, rather than of their specificity, that vaccines operate for good.

Diet.

The belief that diet is of great importance in the treatment of rheumatic conditions, though up to a point well founded, has proved a source of considerable revenue to the vendors of the various "nature cures" which from time to time become popular. Most of our scientific knowledge of the value of dietetic methods in arthritis is recent, and we owe it to Pemberton and his co-workers in America.

Some fifty years ago the idea arose that this group of diseases was due to the presence of uric acid in the blood stream, and foods whose end-products included uric acid were forbidden. Chief among such foods are glandular organs (liver, etc.) and "red" meat. Most of us must have suspected at times that these foods were less harmful than was generally supposed; it is therefore interesting to note that the American workers find that in cases with an accompanying anaemia they are actually indicated, for the reason that, as in pernicious anaemia, they regenerate the blood and resistive powers. The basis of most of the "cures" advertised is a period of actual or partial starvation. The belief that the lower bowel plays an important part in the etiology of the rheumatic diseases has led to the establishment of "Plombières clinics," or, as the Americans call them, "colon-filling stations." The fact that undoubted benefit often follows colonic irrigation suggests that it is worth trying to control the formation of harmful end-products so far as possible, both quantitatively and qualitatively, by means of dietetic limitation and selection. The association of dyspeptic disorders with rheumatism has also been noted, and in view of both of these indications for a lowered diet we are driven back some way towards these empirical "cures" in our effort to lighten the load on the internal organs. Experience does, in fact, show that limitation of diet, particularly the carbohydrate constituents, is a successful adjunct to other treatment, except where there is an obvious focus of active infection.

The chief foods to restrict are bread, potatoes, rice, pastry, jam, and sweets. Vegetables are valuable as "bulk" in a restricted diet, while fruit and small doses of cod-liver oil will furnish the necessary vitamin content. An additional benefit from such a diet is a reduction in weight in the obese patient, and a consequent lessening of the physical load on his lower joints.

Drugs.

Certain drugs appear to be of use in selected cases, the chief among them being the following.

(*a*) *The Iodides.*—This group seems to benefit a minority of arthritics considerably, and may therefore be tried in the treatment of most cases. Colloidal iodine seems ineffective; the same is true of tincture of iodine, though, if we may judge from the reports of the patients themselves, the French 1908 codex tincture, administered in milk (5 minims thrice daily), is of benefit. This may be due to its potassium iodide content.

(*b*) *The Salicylates.*—These drugs have declined in popularity: their "specific" action has never been very noticeable in cases of chronic rheumatism and arthritis. As aspirin they are useful for their analgesic properties. They appear ultimately to increase the misery of the patient's plight by interfering with his appetite and digestion, and causing also a considerable degree of depression. If used they may be combined with the iodides in one mixture. Recently ortho-iodoxy benzoic acid—a drug closely akin to salicylic acid—has been much lauded in America and France for its prolonged effect. Another and somewhat similar drug recommended by Poynton is tolysin, which lacks the depressive action of the salicylates.

(*c*) *Arsenic.*—This drug has been much used, apparently with gratifying results. It is chiefly indicated, as are most drugs, in cases of the "atrophic" type, and should be given in small doses, gradually increased, over long periods. Arsenic is particularly indicated in cases with an accompanying anaemia, but is also of use when the blood count is normal, on account of its effect on the general metabolism of the body. Care must be taken when using this drug that the digestion is not disordered by it. Sodium cacodylate (1·4 to 1·2 grain) is probably the most harmless form to use when this point is being considered.

(*d*) *Thyroid Extract.*—The observation that in rheumatism the basal metabolic rate often tends to be somewhat below normal (G. Holmes, and others) has suggested that there might be a connexion between rheumatism and thyroid deficiency ("suboxidation"), and the prolonged administration of the extract has accordingly been recommended (Llewellyn). Its use is indicated in cases of "climacteric" osteo-arthritis, particularly if there is an accompanying obesity, and good reports are given of the results achieved.

(*e*) *Sulphur.*—This drug is believed by some, notably Cawadias, to be of value in these conditions; it acts probably by disinfecting the bowel, although it can be shown that the sulphur metabolism of the body is generally disordered.

Physiotherapy and Hydrotherapy.

Although the majority of the principles included under this heading were known to the Romans, the actual methods of applying them have been considerably modified during

the present century, largely as a result of the physiological investigations of the American school, and the pioneer work of Fortescue Fox in England. The term "physiotherapy" includes: heat; general and local massage; exercises, active and passive; electrotherapy; the judicious use of rest; and actinotherapy.

Heat.—Heat applied to the body produces diaphoresis, rise in the pulse rate, an effect on the blood pressure, hyperpnoea, increase in basal metabolic rate and protein metabolism, increase in the relative alkalinity of the blood and body tissues, hyperaemia of the skin, "relaxation" in the muscular tissues, and a general sedative effect. These effects are more noticeable when heat is applied generally; they are also observed to a large extent when only local applications are used. It will be seen that heat may be harmful if applied in unselected cases. The commoner devices for applying heat systematically are the radiant heat cabinet, the hot-air chamber (dry heat), hot baths of various types, the vapour bath, and the mud bath (wet heat). Locally it may be applied by means of electric lamps (radiant heat), infra-red apparatus, the high-frequency current (diathermy), local hot-air baths, mud packs, and douches.

Massage.—Massage is used to increase the blood flow through the affected tissues, to open out the smaller capillary beds, to improve the general or local metabolism of skin or muscle, and to delay or prevent the atrophy of muscle which is so often present, either as a primary condition or as a secondary result of disease due to pain or stiffness. Massage should generally be preceded by general or local application of heat.

Exercise.—Active and passive movement should generally be preceded by massage, and, if the movement of the joint is limited by adhesions, great caution is needed, since inadvertent fracture of the neighbouring rarefied bone may then occur very easily. Carried out in the deep pool or reclining bath such movements are among the most important and most successful operations in hydrotherapy, the warmth allaying muscular spasm, and the weight of the water supporting the limb and protecting it from sudden movement, thus engendering confidence in the patient's mind. Most forms of electrotherapy, such as faradism and galvanism, may also be classed as methods of inducing passive muscular movement. The arthritic of moderate grade should be encouraged to follow any sport that is within his powers, otherwise he may become a chronic invalid and his joints may stiffen rapidly.

Rest.—Local rest for an acutely inflamed joint is provided by nature owing to the pain produced by movement. Systemic rest provides a more difficult problem. From a study of the "prodromal" symptoms of twenty-five patients at St. Mary's Hospital who ultimately developed arthritis, I found that in nineteen fatigue or lassitude was the major initial subjective symptom. This may be attributed either to the increased physical difficulty of "carrying on" under a slowly progressive disability, or to the patient's psychological strain as he visualizes the apparently inevitable approach of complete crippledom. Such a state of affairs suggests the need for great caution in applying exhausting remedies until the patient has accumulated some "reserve" to fall back on. Pemberton aptly parallels the progress of an athlete in "training" to the correct course to be followed in the treatment of these patients. Bromides appear to be useful during this stage of the disease.

Actinotherapy.—Ultra-violet light, in combination with other methods of treatment, may help to produce a satisfactory end-result. It is particularly useful to bed-ridden patients with a certain degree of anaemia and malnutrition, and in conjunction with massage is said to raise their blood count in a remarkable manner.

Conclusion.

It will be realized that the range of therapeutic agents in the rheumatic group of diseases is unusually extensive. It will, I hope, also be realized that the multiplicity of these agents does not in this case indicate failure to find a suitable remedy, since it appears to be more and more obvious that the intelligent *combination* of remedies is the keystone of success, the danger lying in the adoption of any one method of treatment, to the exclusion of the rest.

EPIDEMIC CATARRHAL JAUNDICE.

An Outbreak in Yorkshire.

BY

W. N. PICKLES, M.D.Lond.,

AYSGARTH.

No apology is needed for an account of an outbreak of catarrhal jaundice in Wensleydale in the North Riding of Yorkshire when it is stated that more than 250 cases have occurred among a population of only 5,700, living in a part of the valley less than twenty miles long. This paper, it is believed, will help to show the definite spread from case to case rather than from some common source, will confirm the estimation of an incubation period arrived at by Dr. Booth,[1] and will describe unusual points in the clinical characteristics of the disease.

Wensleydale has apparently not been immune from epidemics of this nature in the past; an epidemic of a less serious character in 1910 is remembered. As a recently qualified assistant, jaundice in epidemic form, a zymotic disease unmentioned in my medical curriculum, caused me the greatest perplexity, but my principal assured me that epidemics had frequently occurred in his thirty years of practice. Soon after the date of this epidemic Cockayne's[2] article appeared, distinguishing the disease from the more serious Weil's disease, and suggesting the name "epidemic catarrhal jaundice."

Lately, an account of an epidemic of jaundice in the Midlands has been recorded in a Ministry of Health publication by Morgan and Brown,[3] who sought to establish its leptospiral origin, but without success. A more recent publication by W. G. Booth[4] in *Public Health*, of an epidemic in Surrey, resembles in many ways the one here recorded.

Wensleydale is a broad valley, watered by the River Yore; the altitude of the villages, hamlets, and isolated farms, where these cases were seen, ranges from 600 to 1,000 feet. The water supplies are exceptionally good for a country district, and are separate for each village, the water being neutral in reaction. The district is tolerably prosperous, and there is an absence of poverty with concomitant dirt and ill-feeding. In common with most of rural England, the rat is much in evidence, but there is little likelihood of contamination of foodstuffs, as the standard of domestic cleanliness is traditionally exceedingly high. There is constant communication between the villages, which are united by ties of relationship and friendship, and there is no difficulty in accounting for the spread of an infection, although to trace the actual conveyance of this disease from case to case between the villages has been found difficult.

History of the Epidemic.

The epidemic began in the neighbourhood of Wensley, a village in the lower part of the Dale, in October, 1928. The disease attacked 18 out of 56 children in the Wensley school. No cases appeared in any other of the villages until January 29th, 1929, on which date the disease developed in two boys attending the Askrigg school, ten miles distant from Wensley. Then followed a remarkable spread in this school, 32 out of 81 being affected, the last on July 15th. Bainbridge, the sister village to Askrigg, remained immune until April 16th. The spread of the disease in this village is so significant that it is recorded in full, with dates of commencement of the cases, which appear in monthly crops.

	Illness commenced.
Harold P., school child	April 16th
John T., ,, ,, ...	May 14th
Harry B., ,, ,, ...	May 16th
Frank P., ,, ,, ...	May 19th
Mary M., ,, ,, ...	May 22nd
Leonard P., aged 15	May 19th
Jas. M., school child	June 13th
Jas. P., ,, ,, ...	June 17th
Walter B., ,, ,, ...	July 8th
May L., ,, ,, ...	July 24th

S. P., aged 32, who began with jaundice on August 24th, and who sold sweets in the village shop, probably at this point preserved the link.

The next recorded cases are: Hilda M., September 25th; Richard S. and Annie S., October 25th; Peter L., November 17th.

The last case is most helpful in arriving at the incubation period, as, having developed measles on October 18th, he was not at school after October 17th or in contact with any cases of jaundice—that is, for a period of thirty-one days. During this period cases developed in all the villages in the area.

As stated previously, the spread between the villages was found difficult to trace; the following, however, is a clear record of such. According to my list, only five cases developed between September 25th and 30th, and the sole factor in common was that the patients attended a village fete at Thornton Rust on August 28th. After a prolonged search it was found that Dorothy A., an Aysgarth girl, who developed the disease on August 23rd, was also present. She was in the house of one of the victims, and spent most of the afternoon with another, a girl of 16, who developed the disease on September 30th; this latter girl served in a shop in West Burton, four miles away, and was the first case in this village. Other cases developed there subsequently on October 27th, November 4th, and November 5th (two cases), contact being proved with this girl in each instance.

Method of Infection.

The following is typical of the spread of the infection, and occurred in a family of young adults and among their friends:

Name	Illness Commenced.	Remarks
Jane	August 16th, 1929	Infection not traced.
James } Sarah }	September 14th, 1929	
William ...	October 11th, 1929	
G. S. .. .	October 12th, 1929	A great friend of the family, often in the house.
Ann .	November 7th, 1929	
Jennie U. ...	November 8th, 1929	A little girl, inseparable from the family.
W. M. ...	December 4th, 1929	Fiancé of Ann.
D. U. ...	December 2nd, 1929	Two-year-old sister of Jennie U.
Jno. U. ..	December 29th, 1929	Father of U. children.

The intervals here are 29, 27, 28, 27, 26, 27, 26, and 27 days.

An epidemic caused by contamination of water or food by the leptospira or other organism would appear simultaneously over an area corresponding to the distribution of these. This epidemic presents entirely different features, which can be best explained by assuming personal transference, probably by droplet infection.

Period of Incubation.

In families it was noticed that cases either appeared simultaneously or at long intervals. In the "C" family, Tom and Vera commenced on March 17th and 19th respectively, their father on April 17th. In the "K" family, Jack commenced on June 17th; Arthur, attending a different school, in which there were no cases at the time, commenced on July 14th.

There were in all 39 instances of case to case spread, the intervals between which were as follows:

In 6	instances	the	interval	was	26 days.
,, 6	,,	,,	,,	,,	27 ,,
,, 4	,,	,,	,,	,,	28 ,,
,, 7	,,	,,	,,	,,	29 ,,
,, 5	,,	,,	,,	,,	30 ,,
,, 5	,,	,,	,,	,,	31 ,,
,, 2	,,	,,	,,	,,	32 ,,
,, 1	instance	,,	,,	,,	33 ,,
,, 2	instances	,,	,,	,,	34 ,,
,, 1	instance	,,	,,	,,	35 ,,

These figures suggest an incubation period varying from twenty-six to thirty-five days, thus confirming and slightly modifying Dr. Booth's[1] conclusion that it was not less than twenty and not more than forty days.

Period of Infectivity.

The periodicity of the cases in families, of which a typical instance is quoted above, surely suggests that the infective period of any one case is short. If this was not so, it is unlikely that the monthly interval would have been preserved.

Degree of Infectivity.

Close contact appears to be necessary for the transmission of the disease. In the "K" family already mentioned the two boys slept together; a little sister (aged 4), the mother, and the father escaped infection. In another family two grown-up girls who slept together developed the disease on March 21st and April 19th respectively. No other members of the household, which is a large one, were affected.

Age and Sex Incidence.

Out of 118 cases attended personally, 40 were in patients above the school age, a proportion greater than in previously recorded epidemics. The ages of the patients were as follows:

Age.	Cases.
0-5	7
6-10	41
11-15	33
16-20	13
21-30	13
31-40	6
41 and upwards	5

The youngest patient was 2 years old, and the oldest 79. Thus it appears that it is a disease attacking all ages indiscriminately; it occurs mainly among school children simply because the school provides the opportunity of infection. Of the 118 patients, 62 were males and 56 females.

Clinical Features of the Disease.

Cockayne[2] suggested that most cases of catarrhal jaundice were sporadic instances of the disease he described, and the long incubation period renders this feasible. However, in this epidemic, abdominal pain was occasionally of a severity not usually associated with catarrhal jaundice. It occurred in the early stages of the disease, and, combined with vomiting and consequent collapse, gave a picture so like an acute surgical condition that the diagnosis was a matter of great difficulty. The following case illustrates this.

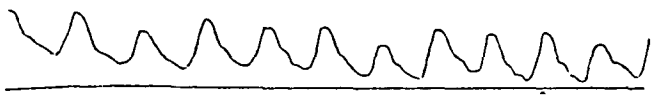
H. A., a farmer, aged 35, on April 17th, 1929, complained of indigestion. On April 21st he was slightly jaundiced, but said he felt better, and asked to be allowed to take a short walk. This concession was construed into a tramp of several miles, including a climb of 500 feet, to see his sheep. On April 22nd, at 7 a.m., an urgent message was received, to the effect that he had had severe abdominal pain for several hours, and had vomited once. He was found to be collapsed, with a feeble and rapid pulse; the face was blanched and pinched. There was tenderness in the epigastrium. The abdomen was full, but not rigid; liver dullness was present; the bowels had not been opened. His condition gradually improved, but he was watched anxiously for several hours, and a diagnosis of perforated duodenal ulcer was seriously considered.

This is not an isolated instance, and it would cause me no surprise to hear that abdomens have been opened in such cases on the assumption that perforation had taken place. What we always deplore—the distance of forty miles from hospital and surgeon—was for once in the patient's favour.

Another apparent difference is the infrequent enlargement of the liver; in only 16 out of the 118 cases was this made out, the edge of the organ being felt in 4. As in other respects the cases conformed to the usual conception of catarrhal jaundice it is not necessary to give the symptoms in great detail. There was a pre-icteric stage lasting from four to ten days, with loss of appetite, nausea, vomiting, abdominal pain, and pains in the back and limbs. The temperature was usually raised, 103° F. being the highest recorded. Jaundice, rarely deep, lasted usually for fourteen days, but occasionally for a longer period, and in the worst case for three months.

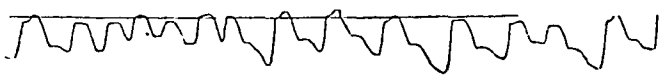
The disease was in marked contrast to Weil's disease, or spirochaetal jaundice. Haemorrhages were represented by epistaxis in three instances, and petechial rashes in two.

about to be carried out by more capable hands, through the kindness of Dr. Burrell at the Brompton Hospital, Dr. Goodchild at Blencathra Sanatorium, Dr. Peill at The Sanatorium, Bridge-of-Weir, Dr. Varrier Jones at Papworth, Dr. Dickinson at Newcastle, and possibly also in Lancashire.



A CASE OF AORTIC STENOSIS.

BY

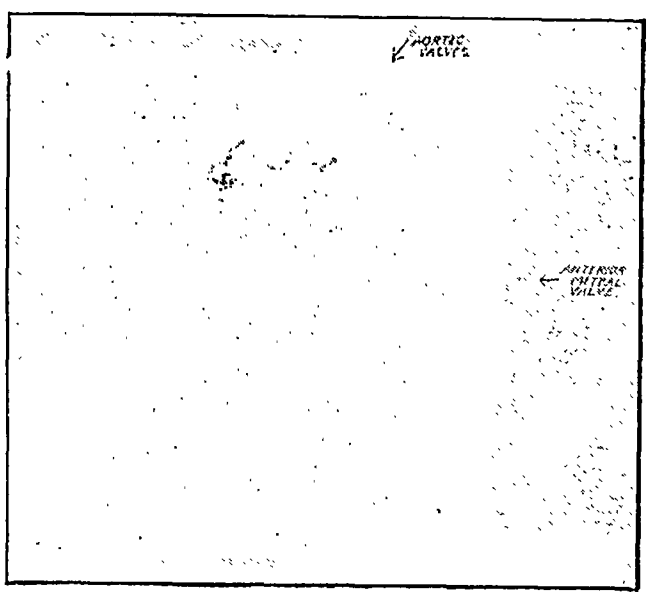


W. HARVEY BENNETT, M.D.,

BOLTON.

THE patient whose case is here recorded was a married woman, aged 53; she had had one child, which died in infancy. She gave a history of being a normal child till

Pulsus alternans, August 7th, 1929.



Auricular fibrillation, August 8th, 1929.

Anachrotic and coupling of beats, August 16th, 1929.

she was 7 years of age, when she had a slow fever with extreme weakness and purpura; she was confined to bed for many weeks, and she never completely recovered her strength, though her general health was good and no medical attention was required till she was about 35 years of age, when increasing shortness of breath compelled her to seek advice. She was then told that she had a very loud murmur, was advised to rest and not in any way to exert herself or hurry—that there was no danger in her

condition provided she avoided strain. The doctor kept her under observation till he died.

She first consulted me in 1926, complaining of breathlessness, dyspepsia, and insomnia. The pulse was 100, with occasional intermission. The area of cardiac dullness extended 5 inches to the left and 2 inches to the right of the mid-sternal line; the apex beat was heaving and well outside the nipple line. A loud aortic systolic with thrill and double mitral murmurs were present.

The dyspepsia and insomnia were relieved by bismuth, magnesia, and bromides. Calcium seemed to relieve the breathlessness, and she continued to take tablets of calcium lactate, 5 grains, daily for about three years, as when she discontinued them she always felt worse.

On June 10th, 1929, the pulse was 84, and there was an increase in the frequency of intermission. She complained of breathlessness, a done feeling in the abdomen, and loss of appetite. The liver was enlarged 2 inches. Digitalis, sp. aether. sulph. co., and tr. card. co. relieved the distress and she went to the seaside for rest and change of air. At the end of a week she returned home, much worse, with pleural effusions reaching symmetrically to the angles of the scapulae, and went to bed for complete rest. She became orthopnoeic; the temperature was raised intermittently to about 100°. The pulse was anachrotic with intermissions—partial heart-block. Pulsus alternans and then auricular fibrillation developed, as shown in the tracings. There was coupling of the beats after digitalis in small doses, but after fibrillating for one week the pulse dropped from 130 to 80. The blood pressure was 140 systolic and 90 diastolic.

On August 8th there was evidently infarction of the right lung, as effusion increased on that side, and blood was found mixed with the fluid when 30 oz. were removed, giving some relief to the dyspnoea. The urine also contained blood at about that time.

Death occurred from cardiac failure on August 22nd, and, though a private patient, I was able to obtain the heart for examination.

The heart weighed 17 oz. The aortic valves were calcified and admitted a finger-tip. Ulceration and vegetations were present on the cusps. The mitral ring admitted two fingers; the valves were thickened but not deformed; there was a deposit of calcium at the base of the anterior curtain. The extent of calcification is shown in the radiogram.

In this case evidently a rheumatic infection in childhood had caused changes in the valves—especially the aortic—which steadily progressed during forty-six years to calcification, and ended in ulcerative endocarditis with infarction of lung and kidneys.

One is in doubt as to the advisability of administering calcium in such cases. The association of auricular fibrillation with infective endocarditis is said to be rare, and is worthy of note.

VALUE OF THE BROMINE TEST FOR DIAGNOSIS OF PREGNANCY.

BY

GLADYS H. DODDS, M.D., D.P.H.,

ASSISTANT IN THE OBSTETRIC UNIT, UNIVERSITY COLLEGE HOSPITAL.

IN the *British Medical Journal* of November 2nd, 1929 (p. 829), C. 1. B. Voge described a new test for pregnancy. The test, which is simple and inexpensive, can be carried out by any practitioner and an immediate result obtained. Voge correlated his findings with those of the Zondek-Aschheim test and found a very close relation between the two. The drawback to the general use of the Zondek-Aschheim test is that it is expensive and requires a laboratory with a supply of immature female mice.

The reaction consists in the detection of the presence in the urine of compounds of the β-iminazolyl type by means of bromine water. Bromine water of ordinary laboratory strength (2 per cent.) is used and diluted with twice its volume of tap water; 1 c.cm. of this solution is added to 2.5 c.cm. of urine in a test tube and the mixture is brought to boiling point. A positive reaction is indicated by the presence of a pink or pinkish-brown coloration, which rapidly fades. In a negative reaction the original yellow colour remains. The reaction of the urine requires to be observed because in acid urine the coloration of the positive test is pinkish-brown, while in alkaline urine it is pink.

Application and Results.

We have carried out the test on 380 patients at the Obstetric Department, University College Hospital. The test was done on fresh urine specimens, and the results are recorded in the following table:

Duration of Pregnancy.	Positive.	Negative.	No. of Cases.	Percentage of Error.
Ante-natal Cases				
Up to 12 weeks	6	1	7	14·2
13-16 ,, ...	9*	2	11	18·7
17-20 ,, ...	25	8	34	23·5
21-24 ,, ...	19	11	30	36·6
25-28 ,, ...	44	20	64	31·2
29-32 ,, ...	34	6	40	15
33-36 ,, ...	12	5	17	29·4
37-40 ,, ...	21	5	26	19·2
Total ante-natal cases	171	58	229	25·7
Puerperal Cases				
1st-7th day of puerperium	24	11	35	
8th-28th ,, ...	17	23	40	
Gynæcological Cases ...	11	65	76	13·1

* One case of hydatidiform mole is included in this group.

It is apparent that the test is not pathognomonic of pregnancy. The error of 25.7 per cent. among the ante-natal cases makes the test of little, if any, value. The urine was pale in colour and of low specific gravity (1002-1004) in a number of the pregnant cases with negative bromine test. This may mean that the urine was too dilute to give a positive result. The test was positive in two cases where the foetus was known to have died twenty-four to forty-eight hours before the test was carried out. The positive result in the case of hydatidiform mole agrees with the theory that the test is dependent on a hormone formed by active placenta. Finally, the error of 13·1 per cent. in the non-pregnant group makes the test valueless in the diagnosis of pregnancy. The ten positive non-pregnant cases were: fibroid 1, retroverted non-pregnant uterus 1, cervicitis 2, prolapse 1, chronic pelvic peritonitis 1, menorrhagia 1, right-sided pain 1, and chronic pyelitis 2.

Conclusion.

It is clear that the bromine test is not pathognomonic of pregnancy, although the frequency with which a positive result is obtained is interesting and suggestive.

I am indebted to Professor F. J. Browne, director of the obstetric unit, University College Hospital, for permission to publish these results.

THE FAMILY INCIDENCE OF JUVENILE RHEUMATISM.

BY

N. GRAY HILL, *M.C.*, M.B., B.S., D.P.H.,

AND

MARY ALLAN, M.A.

INFORMATION has been collected from the parents of 400 of the rheumatic children that have been nursed at Queen Mary's Hospital, Carshalton, relating to the incidence of rheumatic manifestations in their families. The knowledge so obtained has been briefly summarized in the three following tables.

TABLE I.

Total number of families investigated	... ...	400
Total number of children in these families	... ...	2,156
Total number of rheumatic children in these families		540

TABLE II.—*Showing the Composition of the 400 Families, and the Number of Rheumatic Children in them.*

Families with	1	child	...	19;	rheumatic children	...	19
,, ,,	2	children	...	51;	,, ,,	...	56
,, ,,	3	,,	...	70;	,, ,,	...	81
,, ,,	4	,,	...	41;	,, ,,	...	59
,, ,,	5	,,	...	45;	,, ,,	...	66
,, ,,	6	,,	...	47;	,, ,,	...	67
,, ,,	7	,,	...	32;	,, ,,	...	48
,, ,,	8	,,	...	28;	,, ,,	...	38
,, ,,	9	,,	...	19;	,, ,,	...	32
,, ,,	10	,,	...	18;	,, ,,	...	27
,, over	10	,,	...	29;	,, ,,	...	44
Total			...	400	Total	...	540

TABLE III.—*Showing the Number of Parents with a History of Juvenile Rheumatism.*

Both parents	6 cases	= 1.5 %
Father (*but not mother*)	49 ,,	= 12.25%
Mother (but not father)	67 ,,	= 16.75%
Neither parent.	278 ,,	= 69.5 %
No family history of juvenile rheumatism	171 ,,	= 42.75%

In some cases it has been rather difficult to assess the value of the histories given by the parents about themselves, and still more so about their more distant relatives, but the information concerning the patients' brothers and sisters should be fairly reliable. The term "rheumatism," as commonly used, denotes many different pathological conditions, and embraces rheumatoid arthritis and even osteo-arthritis, fibrositis, myositis, myalgia, and other more *ill-defined maladies, so that the answers to questions are* often difficult to interpret. It is possible, of course, that in a certain number of instances adults may develop a disease closely analogous to acute or juvenile rheumatism, but *in the great majority of cases they suffer from the* rheumatoid diseases that are distinctly different, although there may be certain etiological factors in common.

For the purposes of this investigation the chronic rheumatic conditions met with among the middle-aged and more elderly have been disregarded, and special stress has been laid on a history of acute rheumatism, rheumatic fever, chorea, or heart disease, or some combination of these ills, *making their first appearance in the parents before the age* of 25. In a certain number of instances a rather arbitrary decision as to the nature of the disease has had to be made from the evidence available.

It is interesting to note that in not one of the large families—those with six children or more—was there a majority of rheumatic children; in many instances only one member of the family shows evidence of the disease. *It is of course possible that a more exhaustive inquiry,* made only after the entire family had passed the age of 25, would show an increased number of rheumatic members; but the present rather limited inquiry seems to indicate *that very few of the brothers and sisters of the rheumatic* patients develop the disease. This is surprising, since they must live under similar environmental conditions, and in all probability will get very much the same amount of maternal care and home comfort, and the same diet, while they are exposed to the same risk of infection and possess the same hereditary predispositions.

In our series there are eight pairs of twins, and in not a single instance have both twins developed recognizable manifestations of rheumatism. A rather striking point is that in only six families do both father and mother give a history of juvenile rheumatism, and in only a comparatively small number of instances is there a history of rheumatism among both the father's and mother's relatives, a point of more significance when the size of many of their families is considered.

There is, however, slight evidence in favour of the view that juvenile rheumatism occurs more frequently in certain families than in others. Excluding the children who have been patients at Carshalton, the families investigated comprised 1,756 children. Probably less, and certainly not more, than 2 per cent. of children develop rheumatism, so that if those other children were absolutely comparable with the rest of the child population, we would expect to find rather less than 35 cases of rheumatism among them, while, in fact, we find 140 cases.

We wish to thank Dr. Gordon Pugh, medical superintendent of Queen Mary's Hospital, Carshalton, for permission to publish these notes.

THE BLOOD PICTURE IN MEASLES.

IN Stitt's *Practical Bacteriology, Blood Work, and Animal Parasitology* (eighth edition) there is this statement: "It has recently been claimed that a leucopenia with a coincident marked reduction in the lymphocytes is characteristic of measles, and this occurs several days before the Koplik spots appear." On page 353, however, is the statement: "The leucopenia and lymphocyte *increase* in measles are important points in differentiating it from scarlatina" (italics mine).

In every one of 30 cases recently under my care I can endorse the first of these conflicting statements. In each instance I had, as a routine measure, made a differential count when the child was in good health, taking the blood at the same time of the day in all cases. When they became measles contacts I made bi-weekly counts, and another immediately at the onset of malaise. Comparing the count in health with that at the onset of illness I found, not only a marked reduction in small lymphocytes, but a marked increase in "others," and a reduction in eosinophils with the usual "shift to the left" and a resulting lower "weighted mean." This was found before Koplik spots—when these were present—appeared. On the strength of these findings I was able to isolate cases some days—up to five—before the rash developed.

The Arneth method was used, counting 200 white corpuscles on each slide, and arranging them in seven groups, as shown in the following table, in which three very severe measles cases are taken as illustrative of the others.

Groups.	Case I.		Case II.		Case III.	
	In Health	Five Days before the Rash	In Health	Three Days before the Rash.	In Health.	Four Days before the Rash.
Polymorphonuclears:						
One nucleus...	9	56	12	60	18	42
Two nuclei	72	88	64	55	62	79
Three or more nuclei ...	53	14	30	4	42	10
Others (large mononuclears, transitionals, mast cell-)	14	34	27	67	28	54
Large lymphocytes	9	3	9	1	10	6
Small lymphocytes	40	5	44	13	37	8
Eosinophils	3	0	14	0	3	1

Incidentally Türck cells were commonly present and a leucopenia of 4,500 to 5,000 was the rule. I have the records of all these cases, should anyone be interested. I am only tempted to publish these results because the literature is difficult to find.

Battle. H. ANGELL LANE, M.R.C.S., D.P.H.

STRANGULATED HERNIA OF THE BROAD LIGAMENT.

THE following is a record of a case, recently attended by me, of strangulated hernia of the right broad ligament, a condition which must be extremely rare, if not unique.

About three years ago the patient, a married woman aged 56, was operated on for pyloric stenosis due to chronic ulcer, a posterior gastro-enterostomy having been performed. On January 23rd, 1930, repeated attacks of vomiting occurred. Abdominal examination revealed nothing definite. On January 30th severe vomiting recurred, but ceased, and again there were no signs. The following day it again recurred, and on examination at 1 p.m. the right side of the abdomen was found to be very rigid, and there was tenderness over the appendix region, but no visible peristalsis. The bowels had not acted for two days; the vomit was not faecal. The temperature was 99.2° F. The colon was washed out, with unsatisfactory result. At a further visit, at 4.30 p.m., it was found that the vomiting had persisted, and that the condition of the abdomen had not changed. Acute appendicitis, or, alternatively, intestinal obstruction due to a band, was diagnosed. At 5.30 p.m. the vomiting had abated considerably; the abdomen was quite flaccid, distension having completely disappeared, and there was no tenderness. The bowels had not acted; apart from this there were no signs. The temperature throughout varied between 97.5° and 99.5°. In view of the history of vomiting and rigidity, however, it was decided to operate, and at 8.30 p.m. the abdomen was opened by Mr. Neil Sinclair. Free fluid was found; the small intestine was injected, and search revealed strangulation of a loop of small intestine through an opening in the right broad ligament between the ovary and the uterus, about half an inch below the Fallopian tube. The opening was about 1 inch in diameter, and about six inches of gut had found its way through from the anterior aspect and lay in the pouch of Douglas. The edge of the opening was firm and white, and was obviously of old standing. The gut was not in the slightest degree adherent. Strangulation was relieved, and the opening was abolished by dividing the Fallopian tube and the portion of broad ligament between the tube and the opening. The patient made an uneventful recovery.

It would be interesting to receive suggestions about the origin of the opening, as there does not seem to be any embryological explanation for its presence. I assisted at the earlier operation, and can vouch for the fact that the broad ligament was not damaged then. The attacks of vomiting and the absence of signs during the period prior to the operation were due, presumably, to temporary strangulations, which became relieved spontaneously.

London, S.W.5. S. CAPLAN.

SPONTANEOUS SURGICAL EMPHYSEMA.

THE case of surgical emphysema following dental treatment reported by Dr. C. B. S. Fuller in the *Journal* of May 10th (p. 862) prompts me to record two other unusual cases of surgical emphysema, which were associated with labour.

About four years ago I was called to the Farnham Infirmary to see a young married woman, aged 23, who had just been confined. Both sides of the face and neck, from the orbits downwards, were distinctly swollen, the swelling, in a lesser degree, extending over the upper part of the chest and back. The characteristic crepitant sensation of air under the skin could be felt all over the swollen area. The nurse who was present at the confinement could not say exactly when the swelling appeared, as it was not noticed until a little time after the baby was born.

A few days later a similar case occurred in the same ward. In the first case labour was rather prolonged, but the other patient was only in labour for a few hours, and everything was quite normal. The patients complained of no pain, and merely had slight discomfort from the swelling, which passed off in a few days. No obvious lesion of the respiratory tract was found, and there was nothing to indicate exactly how the air had got under the skin.

It was remarkable that I should encounter two such cases within a week, for I have not seen or heard of any similar case since, nor have I found any reference to it in any of the books I have consulted.

Reports of Societies.

VACCINE TREATMENT OF DISSEMINATED SCLEROSIS.

AT the meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on May 13th, with Dr. PHILIP HAMILL in the chair, Sir JAMES PURVES-STEWART gave an account of the application in disseminated sclerosis of a "virus" cultivated from the cerebro-spinal fluid.

Sir James Purves-Stewart pointed out that the difficulty of discussing the treatment of a disease like disseminated sclerosis was enhanced because of the nature of the disease, the irregularity of its course, and the frequency of remissions and relapses. Therefore cases of alleged cure which had sometimes been published fell into one of two categories: errors of diagnosis, and examples of prolonged spontaneous remission. The treatment of this disease could be conducted on two different lines by drugs, and by a specific

or causal treatment. Among the drugs found most useful hitherto was arsenic in some shape or form, especially the arsenobenzol group, and, best of all, silver salvarsan. A second line of drug treatment consisted of colloidal silver, iodine, and mercury. Another line of treatment employed exogenous vaccines, a certain number of results had been quoted. Since 1927, his colleague Miss Chevassut, working in the research laboratories of the Westminster Hospital, had succeeded in nearly 200 consecutive cases of disseminated sclerosis in cultivating from the cerebro-spinal fluid an ultra-microscopic virus. In some cases the result was at first negative, but when the arsenic which was being given in these cases had been stopped for several weeks and the cerebro-spinal fluid was re-examined, a positive result was obtained. She had had 269 control cases with consistently negative cultures. The speaker showed photomicrographs of the *Spherula insularis*, as the organism was called, and drew attention to the characteristic sphere, with the granule attached, a large sphere being about 1 10,000 of the diameter of a blood corpuscle. The virus grew best when incubated at blood heat, and the growth of the culture required from twelve to seventy-two hours. After describing certain observations on animals injected with the culture, Sir James Purves-Stewart said that vaccines had been prepared by Miss Chevassut from actively growing cultures, and, after successful injection, an antibody developed in the blood which was inhibitory to the patient's own virus, and sometimes to the virus of other patients. Over two hundred patients had been treated, but in only seventy-three so far had the examination been continued sufficiently long to be of value. Among the seventy-three patients who had been under observation for two years and upwards encouraging but not brilliant serological and clinical results had been obtained. In early cases the signs and symptoms came to a standstill, and in some respects improved, there remained, of course, the result of the pre-existing degeneration, of whatever extent. Out of eleven early cases in which the diagnosis was definite, but in which the patient was still getting about quite easily, negative cultures were obtained in five. A certain proportion of moderate cases also showed negative cultures, but in advanced cases there was failure every time. In these cases several series of vaccinations of increasing strength were necessary before even a serological improvement was obtained. Great caution was required in claiming anything for experimental vaccine treatment in view of the well-known tendency to spontaneous remission, but there was one important difference between a spontaneous and a therapeutic remission; in the former case the patient's fluid still showed spherules and granules, and still gave positive reactions, whereas when the remission occurred as the result of vaccine treatment, not only did the patient have a clinical remission, but his cerebro-spinal fluid gave negative reactions.

DR. DOUGLAS MCALPINE put forward some points in favour of arsenic, and suggested that a comparison should be made between this new method and some control cases treated with arsenic alone. He remarked that it would be interesting to learn whether the blood serum of patients treated with arsenic was also inhibitory to the spherule. Recently a French author had described remissions lasting for as long as two or three years following on intravenous injections of a serum from the blood. DR. WILFRED HARRIS congratulated Sir James Purves-Stewart and Miss Chevassut on this work, which, he thought, would turn out to be of far-reaching importance. DR. KINGSTON BARTON said that a drug which seemed to have produced definite changes in the early stages of disseminated sclerosis was silver arsenic. There were a large number of cases which remained more or less stationary under simple treatment as carried out by the mental physician, such as the administration of the sulphates of magnesium, sodium, and potassium. The improvement was probably due to the clearing out from the intestine of some organism which was more or less the cause of the spread of the disseminated sclerotic areas over the nervous system. One of the greatest difficulties in most cases of disseminated sclerosis seen in private practice was the question of the bladder, most of the patients developing bacilluria. Many years ago he was indebted to Sir James Taylor for a hint how to control a symptom which was a severe one in many cases—namely, sleeplessness; the treatment was to give the most minute dose possible of veronal (1/2 grain).

DR. H. CARLILL made a reference to patients sent up with a clinical diagnosis of disseminated sclerosis, and who had had no arsenic for a long time, but in whom the organism was not found. He asked if it was legitimate to continue lumbar punctures for the purpose of trying to find the organism, without which at present no specific vaccine could be given. DR. L. S. KYRIE inquired if in estimating whether one was dealing with spontaneous or therapeutic remissions, it was possible to say that for any group of cases of fairly similar status the interval between the induction of therapy and the onset of remission showed any consistency. DR. W. BROUGHTON-ALCOCK asked up to what stage it would be said that a patient did not respond. Did any injury follow the use of vaccine in the tertiary stage? Must a culture be obtained before diagnosis could be made, or might the diagnosis be clinical? The PRESIDENT wished to know whether in each case the vaccine used had been autogenous, or whether, in some of the cases where it had been possible to get a culture, stock had been used. Did the vaccine deteriorate on keeping, or must it be freshly prepared from the patient's own cultures?

MISS KATHLEEN CHEVASSUT, who had been responsible for the laboratory work, said that it was quite impossible to obtain a positive culture if the fluid was contaminated; one of the great difficulties encountered was the performance of a sterile lumbar puncture. Any trace of contamination was a cause of negativity. Undoubtedly it was worth while to repeat the lumbar puncture, even after three or six months. There was probably some unknown factor which did from time to time upset cultures, and very often patients showing negative cultures in the first instance had given positive ones on subsequent examination. With regard to arsenic, she thought that it had merely a mechanical effect. If the patient had received an intensive course of arsenic a trace of this element in the cerebro-spinal fluid would inhibit the cultures; probably also the effect of arsenic excretion into the cerebro-spinal fluid interfered with the extremely delicate reaction of colloidal gold. She added that the vaccines must be injected intravenously, and must be autogenous; she did not think the vaccine remained effective for more than three months.

SIR JAMES PURVES-STEWART, replying, said that the diagnosis was both clinical and serological. In some cases the clinical diagnosis was difficult, and the serological findings were then valuable, but the pathological report was not the final criterion. In some cases after inoculation the patient became a little sleepy, and in some, after a higher dose, there might be a slight collapse for a few minutes, but these discomforts occurred in a negligible proportion of cases. The extent of the disease was more important than the duration in classifying cases as early or late. He had seen a patient who had had the disease for seventeen years, but so slightly as to necessitate very careful examination for its detection. Serological improvement was manifest after the first course of vaccine injections, and clinical improvement began even during it. Stock vaccine therapy was the ultimate aim, but at present each patient's vaccine was made from his own cerebro-spinal fluid. The Medical Research Council had appointed a panel of clinical and experimental pathologists, who would independently investigate these cases both bacteriologically and clinically; it would be a couple of years before the benefit of their work was forthcoming, and at the end of that time it would be known whether this treatment had any value.

RADIUM TREATMENT OF CANCER OF RECTUM.

AT a meeting of the Subsection of Proctology of the Royal Society of Medicine, on May 14th, Mr. CECIL ROWNTREE presiding, a discussion took place on the radium treatment of carcinoma of the rectum.

Sir CHARLES GORDON-WATSON, who showed a cinematograph film illustrating the surgery of access and implantation of radium, said that the first discussion on this subject took place under the auspices of the Subsection in November, 1927. At that time he had been treating

cases with radium for two and a half years, but he had only 15 cases on which to base his observations. His experience of the method now extended over five years, and he had been able to treat with radium over a hundred cases, but he still felt that he had not sufficient experience either to indicate what treatment should be adopted or to express any definite views as to results. On the previous occasion he had shown some cases, one being that of a woman with an inoperable growth, treated by colostomy, exposure of the rectum from behind, and radiation by needles from behind and from the vagina. The carcinoma was transferred into the fibrous structure of the rectum, and the case had been demonstrated again that evening, quite well four years after treatment. Another case shown on the previous occasion was an operable one, with a comparatively small growth on the anterior wall, which he had irradiated. That growth completely disappeared, and when shown at the last meeting the patient had been well for about a year. A year and a half after treatment the patient was anxious to have the colostomy closed. Unfortunately, as a result of the operation, haemorrhage occurred at the line of junction, and the patient died. This was a great tragedy, but it enabled a careful examination of the rectum to be made, and no trace of carcinoma was to be found anywhere. The first case showed that an inoperable carcinoma of the rectum was not always radioresistant, and the second, that a carcinoma at the operable stage could be completely destroyed and leave a patent rectum. At that time he regarded a preliminary colostomy as an essential part of radium treatment. Since then he had treated a number of cases without colostomy, and one man had been demonstrated that evening who, after treatment, without colostomy, by a posterior exposure, open operation, and needling, had only a scar in his rectum to show the site of the carcinoma.

The great obstacle to efficient radiation, as everybody realized, was difficulty of access. If surgical access was easy, there must be a good reason for preferring radium to radical surgery; if there were no special reasons for not recommending surgery, good reasons must be shown for advising radium. The strongest argument that could be urged for radium in a case considered suitable for radical surgery on both local and general grounds would be a reasonable prospect of destruction of the growth with restoration of rectal function, and without expectation of recurrence—in other words, the growth must be destroyed, and not leave any rectal stricture. A colostomy must be avoided, or at least closed at the conclusion of treatment. He had treated a few cases successfully in that way, but he was quite unable to promise freedom from recurrence. On the other hand, some cases of the operable type, which seemed to offer equally good prospects, had either responded and relapsed or had failed to respond appreciably to radium, and had been submitted to radical surgery after radium treatment. How far radiation prior to radical surgery was a factor in preventing subsequent recurrence could not be stated, but it was certainly a matter for consideration in the future.

With regard to inoperable and borderline cases, individual standards as to operability varied, so that the borderline case could not be defined, but there was general agreement in defining the advanced inoperable case. How far could these cases be helped by radium, and what were the chances of doing more harm than good? Everybody recognized that after colostomy, in the absence of liver metastasis, both the general and local condition of the patient improved in the great majority of cases. If colostomy was followed by radiation it was not easy to say whether the improvement was the result of the radium or of colostomy, or both. Even in cases which had been submitted to colostomy some months previously to radiation, rapid marked general improvement followed radiation, though marked local changes might be absent. The outstanding problem was to secure adequate and uniform radiation. To effect this a combination of methods was often necessary.

The borderline case offered the most useful field for radiation (Sir Charles Gordon-Watson continued), either as a forerunner of excision, or in some instances with prospects of cure without excision. His first attempt to treat a high rectal growth by radiation through the abdominal wall was made in January, 1928, and after mo than two years the result remained good, with no eviden of carcinoma in the rectum. He wished he could sho other cases as good, though there were others which ha made wonderful improvement, the growths in several i stances having shrunk. The efficiency of the radiatio depended on the extent of the growth and the presen of adhesions. It might in some cases be fairly easy define the limits of the growth and secure a unifor barrage; in other cases it might be absolutely impossibl If needles were employed drainage was essential. The di advantage of needles was that they required to be remove radon "seeds" were safer, but less efficient. No dou the better results obtained with needles were due to constant intensity as opposed to the diminishing intensi of the emanation. When possible, he liked to use t needles with a filter of 0.8 mm. platinum. Recurren seemed more likely with radon "seeds" than with needle The combination of the two minimized the loss of intensit but, of course, even then a uniform intensity was n obtained.

In cases of local recurrence after excision radium w of great value, especially if the recurrence was treate early. It gave hope to those who were beyond surgic help, and in moderate doses had a remarkable tonic effe on the general health. Time would show whether selectio combined with increased experience and skill, would vast improve results, or whether radium was too capricious master and too unstable a servant to be reckoned wi as a serious fighting factor in the campaign against cance It was not enough to say, "Here is a cancer of the rectum let us excise it"—or, "Let us use radium." An indi of sensitivity was required, with corresponding dosag A technique ought to be developed which allowed no u certainty in the application of the indicated dose, and f help on these lines one must look to the physicist, t biochemist, and the pathologist.

Dr. A. LACASSAGNE (assistant director of the Radiu Institute, Paris) said that neither the new nor the o radium methods had succeeded in bringing about the cu of rectal cancer. About fifty cases had been treated at t Radium Institute in Paris, most of them very advance with extirpation out of the question; but this number, sm as it was, and unfortunate as to the character of the cas was sufficient to allow of a conscientious trial of each the principal methods of radiotherapy, including cur therapy with a 4-gram "bomb." Two of the patien appeared to have been completely cured, the cure havi lasted in one case for eight years and in the other for fo years, but this result had been effected only with the he of surgery. The poor results were explained by l radiosensitivity, and were the more remarkable in contra to the good results in cancer of the cervix uteri. In Pa surgery remained the line of treatment, with radium as palliative in inoperable cases.

Mr. STANFORD CADE said that there were wide variatio in radiosensitivity according to the state of cell develo ment and the presence or absence of mitosis. There was threshold of intensity and a threshold of time, and if the were not reached the attempt to obtain amelioration of t disease failed. The use of radon or emanation was i compatible with uniform intensity. The method of inse ing radium into the lumen of the bowel was frankly ba the intrarectal interstitial method was applicable in vario ways, while telecurietherapy or treatment by "bomb was at present on trial, and it was too early to recomme or condemn the method, though one of its advantages w the multiplicity of ports of entry which might be use Pre-operative radiation was advisable in borderline cas provided the radiation was correctly carried out, and t operation not delayed beyond three or four weeks aft radiation. His own cases included a number of failur but there were some which were encouraging, and h general conclusion was that at present surgery had fi place, but that it was reasonable to anticipate radiu becoming the method of choice in the near future.

Mr. J. P. LOCKHART-MUMMERY regarded radium trea ment of cancer as still in the experimental stage, but was just at that stage that discussion was of the greate value. He thought that the use of stronger filtration w

important. Small doses for a long period gave by far the best results. Ten days were better than seven, other *factors being equal. He believed the milligram-hour* formula to be absolutely useless; it left out of account the size of the growth. Any formula which did not take into account the cubic capacity of the growth was fallacious. He agreed that radon "seeds" offered an easy way of using radium in the abdominal cavity, but they were not so efficient as needles, and at present needling was attended by not a little risk. To secure a more rapid healing of the wounds in these operations he had been using a light packing with vaseline gauze or gauze soaked in oil. His general conclusion was that radium could not be considered a substitute for operation where operation was possible.

Mr. W. S. PERRIN had treated with radium four frankly *operable cases. Two were qualified successes, and the* other two must rank as utter failures. After these latter cases he had not felt it right to recommend anybody to have radium for an operable growth of the rectum. Mr. J. E. C. NORBURY said that different growths reacted to radium in different ways. Of two cases of apparently exactly the same nature one would do extraordinarily well, and the other, with the same dose of radium, would show no effect whatever. One point which might be worth investigating was suggested by the fact that in deep x-ray treatment the effect was augmented by painting with fluorescein. Possibly in the treatment of the rectum by radium some form of injection might be given which would have the effect of increasing the radio-sensitivity of the growth.

Mr. E. T. C. MILLIGAN pointed out the value of radium in carcinoma of the anal region. Before radium was available it was often the fate of the patient to lose his rectum on account of carcinoma of the anus. The speaker had treated several cases of this nature; the only difficulty had been extension of the growth up into the rectum. With regard to radium burn, which might follow treatment of the growth at the anal canal and rectum, a friend of his, who was present at the meeting, Dr. James, an American medical man, had pointed out to him a useful method of amelioration—namely, by the conversion of the radium burn into a diathermy burn. Relief was gained and healing much quickened. Dr. JAMES, speaking further on this point, said that with a radium burn which was sensitive to diathermy the relief of pain on applying the latter method was very marked. Coagulation should go to the depth of the burn. The cases healed very rapidly—in fact, just as quickly as an ordinary open wound. Mr. W. T. WARWICK said that for certain growths a heavy dose of radium might advantageously be given for a short time, but the majority of growths reacted better to a small dose for a longer time. At St. Mark's the method of applying radium was to give a certain grading according to the layer which the growth had invaded, but this did not take into consideration the type of cell or the type of tissue reaction, all of which had to be considered. Something more was needed than the classification of the growth on an anatomical basis.

LIPOID NEPHROSIS.

AT a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, on April 25th, with the president, Dr. R. J. ROWLETTE, in the chair, Professor MOORE read notes compiled by himself and Drs. W. M. O'Farrell and R. A. Q. O'Meara on a case of lipoid nephrosis, and demonstrated the doubly refractive granules in the urine.

Professor Moore said that the patient was a man, aged 34 years, who had oedema and a large amount of albumin in the urine. The blood pressure was 170/100. There was a small right basal pleural effusion, achlorhydria, and a mild secondary anaemia. The phenolsulphonephthalein excretion was 60 per cent. in two hours, and the water output was somewhat diminished, but the fixation of the specific gravity of the urine was normal. In 100 c.cm. of blood there were 28 mg. of urea, 2.5 mg. of uric acid, 1.4 mg. of creatinine, 600 mg. of cholesterol, 8.9 mg. of calcium, 1.4 mg. of phosphorus, and 456 mg. of chlorides. The Wassermann reaction was negative. The basal metabolic rate, estimated at a time when the oedema had practically disappeared, was *minus* 12 per cent. The urea concentration test was normal, the blood serum was milky, and the total amount of albumin excreted in twenty-four hours was 44.8 grams. Estimated as grams in 100 c.cm., the total blood protein was 2.5, the albumin 1, and the globulin 1.4, a reversal of the normal albumin-globulin ratio; *these figures, however,* improved to 5.8, 3.1, and 2.5 respectively before discharge. Doubly refractive lipoid granules were found in abundance free in the urine and in the casts, whether hyaline or fatty. The retinal arteries showed a very slightly increased light reflex, and the walls were slightly and irregularly thickened, there being a tendency to compression of the retinal veins under arterial crossings. Dr. O'MEARA gave details of the technique of examination for the doubly refractive granules, and discussed their source and the significance of their presence in urine. Dr. W. M. O'FARRELL briefly described his biochemical findings, alluding to the importance of rigorously careful technique, especially in such examinations as the estimation of serum *proteins and calcium.*

The PRESIDENT was glad that Dr. Moore had not demanded that lipoid nephrosis should be assigned a specific clinical entity, since at present it was difficult to particularize thus any condition of the kidneys. Dr. A. R. PARSONS raised the question whether the white serum was pathognomonic of lipoid nephrosis and would give the doubly refractive effect, or whether it was only found in the urine. In a case recently under his care, and regarded as nephrosis, the patient was very dropsical; the serum was at first quite clear, but later became absolutely white. Dr. E. T. FREEMAN mentioned the case of a woman recently under his care in hospital, and very similar to the one described by Dr. Moore. In the urine similar doubly refractive crystals were found, but not in so large a number as in Dr. Moore's case. The blood urea was normal, and the cholesterol was 627 mg. per 100 c.cm. The blood pressure was 118/75. The patient had been on a milk diet, and Dr. Freeman thought that much of the weakness from which she suffered and the appearance of the white fluid were due to insufficiency of the diet. The oedema had now completely disappeared, and the urinary output was always approximately equal to the increase in the patient's intake. He thought the presence of blood corpuscles in any large number must imply damage to the glomerulus, and that therefore this was present in Dr. Moore's case.

Dr. V. M. SYNGE referred to the fact that Dr. Moore's case had started with an acute attack, while in the text-books it was stated that lipoid nephrosis should start gradually. The blood pressure was 170, which for a man aged 30 was high; this also was not a characteristic of lipoid nephrosis. He wondered if this condition was really *any different to that which was formerly described as* "large white kidney" and "large white body." He mentioned the advantage of high protein diet in these cases, and added that some patients for whom he had prescribed Epstein's diet had not done well, and had suffered from headache. Dr. GEOFFREY THOMPSON said he had only seen one case of lipoid nephrosis, which was very similar to the one described by Dr. Moore. He asked if any particular value could be attached to the basal metabolic figures obtained, and remarked that an error of about 4 per cent. was allowable even in a normal case. Dr. A. HALPENNY stated that the work of Dr. Bell in America had led him to believe that cases of lipoid nephrosis were really cases of glomerular nephritis. Dr. G. E. NESBITT thought that this syndrome would fit in fairly well with the cases which used to be classified as parenchymatous nephritis.

Dr. MOORE, replying, said he did not suggest the essential unity of lipoid nephrosis. It was described in the literature as a clinical entity, and it was as such that he had shown his case. He believed that the condition was a syndrome only, and though the figures obtained by basal metabolic estimations were interesting, he would not let them dominate his clinical instinct. From recent clinical studies it would appear that glomerular changes were found fairly early in the disease.

Reviews.

DISEASES OF THE SKIN.

FOR some time past Dr. W. FRIEBOES has been bringing out in serial numbers an important atlas of skin diseases.[1] This is now completed by the appearance of the final section, which consists of thirty-two coloured plates, produced with all the skill and taste possessed by Continental colour printers. The completion of this great work is also accompanied by the simultaneous publication of a textbook of skin and venereal diseases[2] by the same author. The textbook itself is not illustrated, but where necessary reference is made in the text to the plates of the atlas. This method of publishing text and illustrations in separate volumes has some undoubted advantages. The reader is able to keep the illustration before him continuously while he is studying any particular condition; moreover, a textbook illustrated liberally enough to compete with Dr. Frieboes's atlas would be exceedingly cumbersome and heavy to handle. The textbook covers its subject-matter fairly exhaustively; it is modern though its arrangement is quite empirical. After preliminary chapters describing the position of dermatology in medicine, the nature of the primary lesions found in skin diseases, and the various methods to be employed by the physician in making a diagnosis, Dr. Frieboes begins his nosology with eczema, a disease which may be regarded as still the most important of all skin diseases; he next considers psoriasis, still the bugbear of the practising dermatologist, and subsequently goes on to the discussion of the principal dermatoses without much regard for any particular system of classification. In this he is probably wise, for no system of classification is yet satisfactory. His treatment of the whole subject is sound, but at one or two points he has omitted to mention work which deserved inclusion. Thus, he says nothing about the eruptions that have recently been shown to be due to the activity of moulds of the genus *Monilia*—which seems to be far more important than was at one time thought—and apparently he is unacquainted with the work done in this country by Garner with MacLeod and Dowlings on seborrhœa. These observers have shown that in all probability seborrhœic eczema is due to the organism formerly known as the spore of Malassez—which by cultivation they have now proved to be a member of the *Monilia* group. It is time that this work obtained more recognition from Continental dermatologists and pathologists. On the other hand, the author lays considerable stress on the dietetic treatment of lupus vulgaris. It appears that animals artificially infected with tuberculosis show a greater resistance if fed on salt-free diet, and this principle has been applied to the treatment of human tuberculosis. At Giessen it is claimed by Gerson that good results are obtained in the treatment of lupus and surgical tuberculosis by keeping the patients on a diet free from sodium chloride, while giving them a mixture of special salts several times daily; at the same time their carbohydrates are severely limited. It is also claimed that this diet is very helpful in promoting the absorption of keloid scars and the plaques of scleroderma. So far, however, this method of treatment seems not to have been adopted in this country. Altogether we can recommend Dr. Frieboes's textbook and atlas as good and solid contributions to dermatology, and no doubt they will enjoy a well-deserved popularity in German-speaking countries. It is hardly necessary to recommend it to the study of British students, who will find their wants sufficiently catered for in their own language. But those who specialize in dermatology will find in it several matters of interest.

Owing its inspiration to Dr. Frieboes is a little book by Dr. A. Ruete, entitled "A Guide to Differential Diagnosis in Dermatology."[3] This book deals, of course, with the problems of clinical diagnosis alone. It is arranged in chapters which follow the various regions of the body from the head to the heel, and thence to the mucous membranes. In each chapter the author describes the different types of dermatoses to be found in a given region, and points out their salient characteristics and how they are to be distinguished from one another. Throughout the work, the reader is referred for more detailed information to Dr. Frieboes's textbook, and is given the exact page on which he will find it. As a matter of fact, this little guide will be found very useful to the practitioner in diagnosing puzzling cases of skin disease—even to the practitioner who does not wish to go to the expense of purchasing Dr. Frieboes's large textbook. Supposing that he is in trouble over some eruption on the arm, he will refer to the chapter on the limbs, and will have a good chance, by comparing his own case with the various descriptions there given, of solving his problem. It is a little surprising that the diagnostic problems of dermatology are not more often approached in this practical way. With the exception of Sabouraud's *Regional Dermatology* and one short textbook of dermatology on these lines written in English, we know of no rival to Dr. Ruete's work.

AMERICAN MEDICAL WAR HISTORY.

THE twelfth volume of the history of *The Medical Department of the United States Army in the World War*[4] comprises two sections, the first being devoted to the pathology of acute respiratory diseases, and the second to the pathology of gas gangrene following war wounds. These subjects were chosen because they appeared to be the most important to the United States Army from the pathological standpoint. Owing to the prevalence of acute respiratory diseases in the training camps, medical officers had exceptional opportunities for studying and reporting on these diseases, and they were especially encouraged to send pathological specimens to the Army Medical Museum.

Acute respiratory diseases had proved a grave cause of sickness and death in the United States armies on occasions prior to the great war, notably in the war of 1812, the Civil War 1861–65, and during the mobilization on the Mexican frontier in 1915–16. In the years 1917 and 1918, when the United States Army was preparing at home an expeditionary force for service in France, there were three periods of high incidence of acute respiratory diseases; and of these, the third, which corresponded with the pandemic outbreak of influenza, was far the most serious. No single type of lesion predominated, typical lobar pneumonia was infrequent, broncho-pneumonia was common, and in cases where the consolidation was widespread necrosis often resulted, with the formation of abscesses and gangrene. An acute type occurred in which a dripping frothy haemorrhagic lung was found at autopsy. It was in such cases that the influenza bacillus was commonly found. In some instances haemolytic streptococci invaded the lung, causing death within a few days. The lungs from such cases showed more haemorrhage than when the influenza bacillus alone was present. But the most striking difference appeared to be a leucocytic infiltration rather than oedema of the alveolar walls. In spite of the most careful bacteriological work the conclusion come to regarding the cause of pandemic influenza is that there is more evidence pointing to the influenza bacillus than to any other organism, but no definite conclusion can yet be arrived at. The numerous illustrations, some of them in colour, of the macroscopic and microscopic appearances in the various acute respiratory diseases render this volume of the greatest interest to general pathology, apart from any particular connexion with warfare.

The second section of the book, which deals with the pathology of gas gangrene following war wounds, consists of only 17 pages of letterpress and 43 of the most admirable illustrations. The important part played by the bacteria of the soil is clearly brought out. A novel suggestion is made that in some instances the burrows of scabies were

[4] *The Medical Department of the United States Army in the World War.* Prepared under the direction of Major-General M. W. Ireland [illegible]. xii: *Pathology of the Acute Respiratory Diseases, and of Gas [illegible]angrene following War Wounds.* Washington: Government Printing Office. 1929. (Sup. roy. 8vo, pp. xiv + 583; 312 figures, 24 plates. 3.60 dollars.)

carried deep into the muscle by shell fragments, thus introducing the exciting factor of the infection into an ideal situation. The combination of other bacteria with *Bacillus welchii* sometimes appeared to modify the virulence of the latter. The presence of frank pus producers like the staphylococci checked the progress of gas gangrene. This probably accounts for the reverence which surgeons in earlier wars had shown for "laudable pus" in connexion with gangrenous wounds. Infection with anaerobes showed a high death rate but a short period of danger to life unless streptococci were associated with the anaerobes. The observations made in the American Expeditionary Force confirm the importance of circulatory failure in the production of gas gangrene. Apparently the bacteria alone are incapable of producing gas gangrene. In all probability the local ischaemia produced by damage to the circulation ranks second only in importance to intensive damage to muscle, under conditions that prevent the full access of oxygen. Although *Bacillus welchii* is only one of several anaerobes which can produce gas gangrene, it was the predominating anaerobe responsible for gas gangrene during the great war. The illustrations in this section are equal in value to those on respiratory diseases.

THE DRAMATIC IN SURGERY.

In his little volume entitled *The Dramatic in Surgery*[1] Mr. GORDON-TAYLOR has concentrated some extraordinary examples from his immense surgical experience. They are of real value to the practical surgeon as showing him difficulties with which at any time he may be confronted, and as showing him how even the most difficult problems may be successfully solved. They range over every aspect of surgery from the removal of a colossal tumour of the innominate bone to a successful suture of the heart for a gunshot wound; and from the removal of a clot for pulmonary embolism to a cosmetic reconstruction of the breast.

The surgeon who can peruse this book without learning something must be mentally blind, and if he does not enjoy reading it he must be devoid of any sense of humour: but he will lay it down feeling a grudge against the author that he does not more often allow his colleagues to share his experiences and enjoy his wit. Superb illustrations and production add to our enjoyment of this most attractive volume.

RADIOLOGY OF THE NECK.

The *Handbook of Roentgenology*, edited by Dr. JAMES T. CASE, is a series of monographic atlases each dealing with the radiology of one or other of the organs or systems of the body. The ninth volume, entitled *The Neck*,[2] by Dr. PERCY D. HAY, jun., is dedicated to Dr. Henry K. PANCOAST, who contributes an introduction, in the course of which he gives a history of the research from which data in the monograph were derived. One of the difficulties in the interpretation of radiograms of the neck is in the fact that normally the structures of the laryngeal region present a diversity of appearances. Dr. Hay's study is concerned mainly with the radiology of the soft structures of the neck, and as very little exact work had previously been done on this subject he had in the first place to elaborate and to standardize a technique for establishing the cause of the normal shadows. This technique he explains minutely, and discusses the results of his examination of fifty adults and twenty-five children. Beautifully reproduced radiograms of these cases show the shadows produced by different parts of the pharynx, larynx, trachea, the œsophagus, and other soft parts, and establish a standard for comparison with other radiograms in which evidence of some pathological condition is sought for. Without some definite guide of this kind the radiologist might easily overlook conditions causing slight deviations from the normal shadows.

Having established the normal Dr. Hay proceeds to describe and illustrate the *x*-ray findings in pathological states, including non-specific inflammations, abscesses, tuberculous infections, salivary calculi, syphilis, diphtheria, streptococcic laryngitis, diseases of the thyroid, benign and malignant tumours, diverticuli of the pharynx, neuromuscular conditions, and conditions due to trauma. The author has marked most of the radiograms illustrating abnormal conditions with arrows pointing to the situation at which there is a deviation from the normal. In an appendix he presents a reasoned argument in favour of examining the neck in all suspected thymic cases.

Dr. Hay has written a useful reference book on a hitherto somewhat neglected though obviously important field for *x*-ray diagnosis. He presents his material with great clarity, and the publishers have served him well by printing his book beautifully and on good paper. The bibliography and index are adequate.

LOCAL ANAESTHESIA IN OTO-RHINO-LARYNGOLOGY.

THERE is no region of the body in which the art of local anaesthesia has been brought to greater perfection than the head and neck. Professor CANUYT of Strasbourg has for some years been a prominent exponent of the method, and in collaboration with his colleague Dr. JOUBLOT he presents a systematic account showing that all the operations which belong to oto-rhino-laryngology can be performed efficiently under local anaesthesia.[3] Some of them not only can but should be performed in this manner. Operations on the nose fall into this class, but in this country many operators still do not avail themselves fully of the advantage offered. In tracheotomy for laryngeal obstruction local anaesthesia is indispensable, though the technique described in the book seems unnecessarily elaborate. There is a third class, such as mastoid operation and laryngectomy, where the advantages for many operators are outweighed by the disadvantages, though in some circumstances local anaesthesia must be employed.

There is nothing strikingly original in this book, but everything is very clear and precise. The anatomical points and course of the nerve trunks are shown in diagrams, and the technique of inducing anaesthesia is described in a manner which allows no ambiguity. The whole region including the tongue, jaws, and neck comes under this survey. The authors have also some general observations to offer, in the course of which they give some account of the fatal accidents that have occurred. They realize that there is no absolute security against these, whatever precautions are taken, but they are strongly opposed to the combination of local with general anaesthesia. Ephedrine is still on trial and cannot yet replace adrenaline, but they have found butyn a satisfactory substitute for cocaine.

Although the more elaborate procedures in which deeply situated nerve trunks are concerned are not likely to become popular, there is no doubt that specialists in this country do not employ local anaesthesia so much as their foreign colleagues. Those who wish to give it an extended trial will find this book an excellent guide.

PATHFINDERS IN MEDICINE.

IN 1912 Dr. VICTOR ROBINSON, editor of the Pagel-Sudhoff *Handbook of the History of Medicine*, brought out the first edition of a work containing fifteen lives of the fathers of medicine, and now, in the second edition of the *Pathfinders in Medicine*,[4] he has added fifteen more lives, more than doubled the number of pages, and increased by tenfold the illustrations. This is a collection of essays, published between 1909 and 1929, written in a popular style, but containing a store of information, much personal detail, some autographs, and interesting correspondence of the men he describes. Among the new lives is that of Samuel Guthrie (1782–1848) of Sackett's Harbor, New

York, a country doctor and chemist, who in 1831 made chloroform in a pure form ("Guthrie's whisky"), but "did not realize that he had discovered the waters of the modern Lethe." The account of James Y. Simpson, though it does not mention Guthrie, gives a picturesque description of his inhaling chloroform, and a good deal about Lawson Tait, who "was too original to pass the prescribed examinations" of the University of Edinburgh. In the sympathetically told story of the adventures of the pioneer medical sisters—Elizabeth and Emily Blackwell—the author gives vent to the dictum that "medical societies have too frequently been boulders in the medical path; we have advanced by stumbling over them or by avoiding them." The only living person who receives a full notice is Professor I. P. Pavlov, and he, like Brougham, has had the opportunity of reading several ante-mortem obituaries of himself (including one by Dr. Victor Robinson), for early in 1916 the death of a Russian surgeon of the same name gave rise to the belief that the great physiologist had passed away. The author regards the study of medical history as his consolation or hashish for these days of "the decadence of the human spirit," "the deepening twilight of dying faiths," and "the million-voiced roar of the motor"; for "it is the greatest of stories—the record of man's conflict with credulity."

NOTES ON BOOKS.

THE volume of the Practical Medicine Series on *General Surgery*,[9] edited by Dr. EVARTS A. GRAHAM, contains a concise account of recent advances in all departments of general surgery, including anaesthesia, radiotherapy, and orthopaedic surgery. The text is liberally interspersed with illustrations. We are pleased to find that the work of British surgeons receives ample acknowledgement.

Not many people can afford to possess the ten volumes or twenty half-volumes of the *Oxford Dictionary*, but "for those with small purses and restricted house-room, the authority of the great work flowers in more modest beds." We welcomed last year a new edition of the *Concise Oxford Dictionary*, and the *Pocket Oxford Dictionary* has now been in circulation since 1924. In response to a demand for something still smaller, yet covering the same or even a wider vocabulary, the Clarendon Press entrusted Mr. GEORGE OSTLER with the task of packing all that could be packed into 640 diminutive pages. Before his death a year ago Mr. Ostler had completed the dictionary proper and revised all the proofs. The result of his labours, entitled *The Little Oxford Dictionary of Current English*,[10] is a marvel of accuracy, legibility, and condensation which anyone may have for a florin or half a crown.

The Progress Book,[11] compiled by W. M. PILLEY, is a diary designed to facilitate the literary labours of parents who wish to keep a complete record of the progress and development of their offspring. It is classified in three main divisions—namely, record of development, medical record, and illustrated progress—and in each division there are a large number of sections under appropriate headings. The medical record division includes, among others, the following sections: birth records, ailments in infancy, vaccination record, dental record, and notes on school health examinations. An important section is entitled "Funny sayings." *The Progress Book* will serve a useful purpose if parents make a point of recording each funny saying as soon as they have heard it instead of saving it up for the delight of their friends.

A volume comprising reprints of papers contributed to various medical journals during 1929[12] by members of the staff of the wards and laboratories of the London Hospital has been issued for purposes of reference. In like manner reprints of papers[13] contributed by members of the staff of the Middlesex Hospital Medical School during the session 1928–29 to British and American periodicals have been brought together within a single cover. Both volumes may be consulted at the library of the British Medical Association.

Novial Lexike[14] purports to be a vocabulary of the most necessary words of Novial, a new international auxiliary language. The author, Mr. OTTO JESPERSEN, refers the reader for further information to his book *An International Language* published by Messrs. Allen and Unwin.

Some of our readers may be glad to know that interleaved copies of the *Pharmacopoeia of the Central London Ophthalmic Hospital* are obtainable from the publishers, Messrs. H. K. Lewis and Co., Ltd., at the price of 2s.

PREPARATIONS AND APPLIANCES.

AN ANTIDOTE BAG.

DR. E. BARON (London, N.15) writes: The necessity for an antidote bag, complete with all the requirements, as part of the armamentarium of a modern doctor, is undeniable. This was impressed upon me when I was urgently called to a case of poisoning and found myself without any appropriate antidote to hand. The bag shown in the illustration is the sequel; it supplies the practitioner with a complete ready-to-hand equipment and drugs to deal with any case of poisoning, everything within the bag being visible and accessible as soon as the lid is lifted. The bag contains one or more antidotes for each poison and other treatment required. It is strongly recommended that the pages relative to "Poisoning: symptoms and treatment," which a well-known firm includes in its medical diary, should be placed within the bag ready for reference. The contents are arranged as follows:

The lid accommodates a hypodermic syringe with needles in a case; a box containing three ampoules; a case for tubes of hypodermic tablets; and a box containing many small boxes of tablets. To the sides are attached five wide-mouthed screw-top powder jars; one large and six small screw-top bottles containing liquids; and one mouth-gag with an opening for a stomach tube. In the central space is a stomach tube with rubber funnel (for adults) and a funnel with small rubber tube (for children). Room is left for any personal additions.

The following drugs are included in every bag. *Powders in jars:* magnesium sulphate; magnesia ponderosa; chalk; starch; and dry albumin. *Liquids in bottles:* olive oil; vinegar; French turpentine; castor oil; ether or brandy; spt. ammon. aromat.; and tinct. ferri perchlor. *Ampoules* containing pituitary extract; adrenaline; and ether. *Tablets in large box:* copper sulphate (2½ grains); pulv. ipecac. (5 grains); tannin (5 grains); potassium permanganate (2 grains); ferrous sulphate (5 grains); potassium ferrocyanide (5 grains); potassium bromide (5 grains); sodium carbonate (5 grains); tinct. opii (30 minims); and sodium bicarbonate (5 grains).

Tubes of hypodermic tablets are not included in this bag owing to the Dangerous Drugs Regulations; but it is strongly urged that a tube of each of the following should be ordered at the same time to be placed in the bag in order to complete the equipment: apomorph. hydrochlor. (1/10 grain) cum strychn. hyd. (1/60 grain); morph. hyd. (1/4 grain); strychn. hyd. (1/60 grain); strophanthin (1/100 grain); and pilocarpine nitrate (1/3 grain).

The bag and contents have been prepared for me by Messrs. John Bell and Croyden (Savory and Moore, 1928), Ltd., 50-52, Wigmore Street, W.1.

PATENTING OF MEDICAL INVENTIONS.

PROPOSED SCHEME OF DEDICATED PATENTS.

THE medical profession has for many years concerned itself with the ethical and practical problems connected with the patenting of processes for the production of substances and devices used in the diagnosis, prevention, or treatment of disease. Speaking generally, British medical workers have accepted, and acted in terms of, the view that it is undesirable that any individual should reap direct financial reward from a scientific discovery in the medical field. Their objection to the existing patent system is based in part on their appreciation of the fact that the work of innumerable investigators all over the world helps to build up the knowledge from which one individual, entering the field of work at a propitious moment, may be able to develop a patentable process; in part on their belief that a system of monopoly, by limiting the area over which a scientific discovery may be applied or developed, is contrary to the interests both of the public and of scientific workers. The traditional attitude of the profession in this country is expressed in the two following resolutions, adopted in 1903 and 1920 respectively, by the Central Ethical Committee of the British Medical Association:

> That it is contrary to the ethics of the medical profession to attempt to secure a monopoly in the sale of any article or in the treatment of disease, and especially by patenting any such article in the name of a medical practitioner whose name would necessarily be used in its advertisement.
>
> That it is undesirable for a medical man who has invented a device intended for medical purposes to take out a patent for the purpose of deriving from such patent the financial results of a monopoly.

More recently the committee restated its view in the following general principle, which was approved by the Council in December, 1929:

> That it is ethically undesirable for a registered medical practitioner who makes an invention or discovery in the medical field to derive financial benefit from the sale of the rights of such invention or discovery or from royalties from the use of it.

Later Developments.—Events in recent years have made it necessary for the medical profession to consider afresh how its ethical principles can be most effectively expressed in action. Adopted as a categorical imperative the conduct of the profession in this country would result in the complete abolition of medical patents in all countries, and this would be the ideal solution of the problems at issue. Unfortunately, neither on the Continent nor in America have scientific workers shown any inclination to adopt the ethical code guiding our own profession in this respect; and it has lately become increasingly evident that the patenting of processes for the production of hormones, vitamins, serums, and such products by workers abroad, and above all their practice of taking out "master" or "blocking" patents, based on anticipation of future research rather than on investigations already carried to a satisfactory conclusion, are having a detrimental effect on medical research in this country.

One important fact must be borne in mind: the opposition of the medical profession to the system of patents is based entirely on its desire to further research and protect the public, and whatever force this opposition has it derives from its success in securing these ends. The traditional practice of the profession must, in fact, be judged by its fruits, and if it can be shown that a modification of the present law and custom relating to patents is likely to be more effective in producing a desirable state of affairs then there could be no ethical objection to the promotion of such modification by the medical profession.

Faced with these problems, the British Medical Association set up a special subcommittee of the Central Ethical Committee to discuss and report on the various ethical and practical problems connected with the patenting of medical discoveries, and this committee recently submitted evidence before the Board of Trade Committee formed in 1929, under the chairmanship of Sir Charles Sargant, to consider how far it was desirable to amend the Patents and Designs Acts, or to effect changes in Patent Office procedure. The report of the Association's subcommittee has been published in the Annual Report of Council (*Supplement*, April 19th, 1930, pp. 130 and 150), and it will in due course come for consideration before the Representative Body. In the meanwhile, we are glad to draw attention to the two interesting documents summarized below: the first, a Memorandum on British Patent Law Reform,[1] submitted to the Board of Trade Patents Committee by a joint committee representing the Association of British Chemical Manufacturers and a number of other chemical institutions; the second, a paper on fine chemicals,[2] by Mr. Frank Lee Pyman, F.R.S., director of Messrs. Boots chemical laboratories, in which he examines some of the problems connected with the patenting of new medicinal compounds. The former document embodies a series of proposals which, with one or two small modifications, were accepted by the British Medical Association's subcommittee; the latter is, in effect, a criticism of these proposals.

MEMORANDUM OF THE JOINT COMMITTEE.

Two alternative schemes are considered in the memorandum: (1) the abolition of medical patents; (2) the establishment of a system of medical patents devised to meet, on the one hand, the ethical objections of the medical research worker to patents, and, on the other, the desire for protection on the part of the manufacturer, whose co-operation is essential if the public is to obtain full value from new medical discoveries. A non-patent system does not afford the necessary protection to manufacturers, and may in practice lead to the extended use of secret manufacture and secret remedies, with a restrictive effect on further research. In any case, without international agreement the abandonment of medical patents by this country would place both our research workers and our manufacturers at a serious disadvantage.

Existing Patent Law.

Section 38A (1) of the Patents and Designs Acts, 1907 and 1919 (Consolidated), is as follows:

> "In the case of inventions relating to substances prepared or produced by chemical processes or intended for food or medicine, the specification shall not include claims for the substance itself, except when prepared or produced by the special methods or processes of manufacture described and claimed or by their obvious chemical equivalents, provided that, in an action for infringement of a patent where the invention relates to the production of a new substance, any substance of the same chemical composition and constitution shall in the absence of proof to the contrary be deemed to have been produced by the patented process."

Under this section it is possible to take out patents for medical remedies, and these may be grouped roughly into two main classes: (*a*) definite chemical compounds with a specific effect in certain diseases. Such remedies are usually discovered in the course of purely chemical investigations, and the medical research worker only intervenes at the stage of pharmacological and clinical trials. (*b*) Biological products, such as vitamins, serums, vaccines, glandular extracts, etc. These substances generally originate with the medical research worker, but the chemist intervenes during the later stages, when isolation and investigation of the active principles—for example, adrenaline, thyroxine—is attempted. These two classes may overlap, but it is clear that there are two groups of workers concerned—chemists and medical research workers.

Attitude of the Medical Profession.

Chemists as a body seem to have no objection to taking out patents for therapeutic substances, and, indeed, eminent chemists are to be found among British patentees of such products. On the other hand, a large section of the medical profession is at present resolutely opposed to taking out such patents, whether the products concerned are of purely chemical or biological origin. This opposition they justify on the ground that a patent in relation to any medical remedy tends at first sight to give the impression of making profit out of human suffering, and because they believe that the freer use of patents would result in greater secrecy on the part of research workers, whereas the most liberal interchange of knowledge is essential to progress. The joint committee, while admitting the need for the full and rapid publication of any information

[1] Association of Chemical Manufacturers. Price 1s.
[2] *Journal of the Society of Chemical Industry*, March 21st, 1930.

bearing on medical research, doubts whether the abolition of medical patents would be the best way of securing this end.

The Object of our Patent Law.

The object of our patent law is to stimulate invention by offering a reward, and to extend industry by the application of new discoveries. It succeeds in that object, even though it often happens that the patented invention does not benefit the actual discoverer of the knowledge on which the invention depends. The borderline between invention and discovery is very difficult to define in medical fields. A discovery is often the culmination of years of progressive research by many workers, and it is unfair that the worker who merely applies some finishing touches should be able to reap the monetary reward of the cumulative effort. While such a state of affairs discourages scientific workers who have contributed to the research on which the invention is based, the fact remains that the general motive of most scientific workers is not monetary reward, but the satisfaction that comes from advancing knowledge.

Distinction between Discovery and Invention.

The authors of the memorandum proceed to consider the circumstances connected with the patenting of three important inventions subserving medical treatment.

(*a*) *Insulin.*—In 1923 Dr. Banting made the final addition to a long series of discoveries by which the preparation of insulin was rendered possible. His process was protected by a patent taken out in the name of the University of Toronto, and the British patent rights were offered by the University to the Medical Research Council, whose action in accepting them met with some criticism at the time. The Medical Research Council was animated by two considerations: first, that the patent was better in its hands than in anybody else's; and, secondly, that it was able to control the manufacture of insulin, there being at that time no Therapeutic Substances Act, by which this could be effected. Events have fully justified the Council's action, for insulin of the highest quality is now available at very low cost, owing to the fact that the few firms to whom the manufacture has been entrusted are able to devote considerable energy and capital to its production.

(*b*) *Thyroxine.*—At the time that Dr. Harington published all but the final stage of the synthesis of thyroxine, he decided not to patent this method, and thus left unguarded the possibility that other workers, perhaps abroad, might obtain a monopoly of synthetic thyroxine by discovering the last step. It happens that Dr. Harington was later successful in completing the synthesis, which was never patented. The danger remains that some foreign manufacturer may become possessed of a patent which, though of minor importance in itself, would enable him to cut out the British manufacturer, who would not be free to use the patented, and consequently cheaper, method.

(*c*) *Vitamin D.*—The example set by Toronto University has been followed by Wisconsin University. Steenbock patented the method of rendering foodstuffs antirachitic by irradiating them. Knowledge that some foodstuffs possess antirachitic properties and that the irradiation of animals cured or prevented rickets had previously been acquired by research in which British workers played a leading part. The University of Wisconsin, however, not only used the patent for the purpose of demanding royalties in this country, but claimed that it covered a later and much more important discovery which was unsuspected when the specification was drawn up. This discovery, largely to be credited to workers in this country, and published without any idea of patent application, was that ergosterol becomes vitamin D when irradiated. According to the Joint Chemical Committee, the history of the Steenbock patent illustrates the unfair advantage that can be taken by those making full use of the patent system over those who refuse to do so. Meanwhile the position has become still further complicated through attempts now being made by a foreign firm to gain control of the manufacture of vitamin D by patent applications concerning the particular conditions and methods of irradiating ergosterol.

It thus appears that the results of British research are being exploited by workers in other countries who do not hold the same opinion about the ethics of medical patents. The exploitation is usually effected by the well-known methods of making a small improvement in the published method, and then patenting it in this and other countries; often the result is that the British worker is prevented from using his own discovery.

The Position of the Manufacturer.

In order that full use may be made of new medical substances it is necessary that their production should be efficiently developed on an adequate scale. But before a manufacturer can undertake the necessary financial commitments he very naturally expects some assurance that he will obtain a reasonable return on his outlay. Such assurance is best afforded by protection against unrestricted competition, and the joint committee points out that competition is in fact likely to defeat the object which it seeks to attain—namely, improvement of quality and the reduction of price. Part of the medical investigation carried out in this country is financed by industrial companies, and if these are to be in a position to maintain their research activities they must have suitable protection either by patents or trade marks. The only alternative is the preservation of secrecy, which is admittedly undesirable.

To reconcile the conflicting views of the medical profession and the manufacturers, the British Science Guild, in its report on the reform of the British patent system,[3] makes the following suggestions:

> "That the interpretation of the word 'manufacture' should be extended so as to permit of the patenting of a wider range of biological inventions; and we think that the practical difficulties involved in such an extension are not insuperable. Biological inventions subserving medical treatment should not, however, be patentable in view of the strong contrary opinion of the medical profession."

It would, however, be difficult to devise a formula whereby it could be decided in any particular case whether the product fell within the category "biological inventions subserving medical treatment," and the joint committee suggests that the proposal to differentiate between chemical and biological substances for medicine is illogical and does not afford a satisfactory solution of the problem. It is equally emphatic in condemning the proposal to abolish medical patents. Apart from the objection that such a step would remove the necessary inducement to firms to undertake the manufacture of new remedies, there would be the difficulty that many substances subserving medical treatment have other uses in respect of which a patent would be permissible. Moreover, it is possible that the abolition of medical patents might lead to undesirable secrecy in place of free publication of the results of research. When a new drug is patented the process of manufacture and the composition of the drug are published in the patent specification, and the patentee is given a control monopoly for a limited period. Such publication leads to the development of new ideas and to further investigations, all of which would be lost if medical patents were replaced by "secret remedies." In any case, the joint committee insists that the abandonment of medical patents should not be adopted until international agreement on the subject is obtained; otherwise all markets in countries where patent legislation does not exclude medical patents will, in effect, be closed to British manufacturers. Such restriction on the scale of production would react to the detriment of the British medical profession and the public, as it would be bound to have adverse effects on the price of products.

Dedication of Medical Patents.

As a way out of the present difficulties the joint committee suggests a scheme for the dedication of medical patents to the British public. The scheme would work somewhat as follows. Every British patent in respect of inventions subserving medical purposes would be administered on behalf of the public by a department of State called the Medical Patents Trustee. This department would act in consultation with an advisory committee, on which the medical profession was prominently represented. The trustee would grant as many licences as he thought desirable, or, if necessary, he would declare the invention free and allow no greater amount of monopoly than seemed essential for securing the proper development of the invention. He would offer the first free licence to manufacture in this country to the inventor or his nominee, and then such additional licences as he considered desirable, having regard to all the facts in each case. The fees would be paid to the trustee, and not to the inventor. If the licence was worked to the trustee's satisfaction within the period stipulated he would not necessarily grant any other free licence, though at any time he might grant as many other licences as he thought fit, and make the fees as low as

[3] British Science Guild, 6, John Street, Adelphi, W.C. Price 2*s*.

seemed desirable. If the first free licence was not taken up or was not worked satisfactorily he could, if he wished, declare the invention free or grant as many licences, with or without consideration, as seemed desirable. His one aim would be to ensure that the invention was utilized in the manner in which the public could derive most advantage, both as to quality and price. Under this scheme the inventor would have the first option of taking out foreign patents, and he could then deal with foreign royalties in the usual way; or, if the inventor preferred, the medical trustee could take out and administer the necessary foreign patents, determining the royalties, or, if he thought fit, declaring them free. If it is deemed undesirable that the trustee, being a public official, should administer foreign patents, it is recommended that the option to take out such patents should lie only with the inventor or his nominees. Royalties imposed by the trustee should be no more than sufficient to cover the expense of administering the dedicated patents, any surplus being devoted to medical research. By making such dedication compulsory for all patents for inventions subserving medical purposes, whether taken out by British or foreign workers, the principle would be safeguarded that there can be no uncontrolled monopoly in Great Britain, publication would be assisted, and British workers would be protected from exploitation. Furthermore, the administration of the patents by a department of State would allow of an effective control over manufacturers, and would provide the firms with the necessary inducement to develop new remedies. This scheme the joint committee believes would allow the medical worker to contribute to the application of new knowledge by patent publication without the least suspicion that he is monetarily interested.

FRANK LEE PYMAN'S PAPER.

Mr. Frank Lee Pyman opens his paper by considering the two chief methods by which a new medicinal chemical may be established as a commercial substance: the nature of the chemical substance responsible for the physiological action of some natural material may be discovered, or the variation of physiological properties accompanying variation in chemical constitution may be deliberately investigated. By the first method, in which the sequence of events is clinical investigation of some pathological condition, followed by physiological and chemical research, such substances as thyroxine, insulin, and vitamin D have been introduced into medicine. In the second method the sequence of events is reversed: a series of allied compounds is first prepared by chemists, and then physiologists determine the member of the series having the maximum physiological effect. If then the general toxicity of the compound is low in relation to the probable therapeutic dose it may be submitted to clinical trial. The substances discovered by the first method Mr. Pyman calls "biological inventions"; substances discovered by the second method "chemical inventions."

The Part Played by the Manufacturer.

The private enterprise of commercial firms has resulted in the discovery of many important drugs, and as examples Mr. Pyman cites the extended researches of German firms that eventuated in the marketing of salvarsan, "Bayer 205," and plasmoquine. Such investigations cost a great deal, and manufacturers, not unreasonably, expect a monopoly for a time for the drugs that have been discovered through their enterprise. Moreover, a monopoly gives the manufacturer an incentive to market his product. For example, the virtues of chloramine-T, a non-patented substance, are not widely advertised by manufacturers, for the simple reason that it is more profitable to spend money on advertising preparations held by a monopoly. Another difficulty in reaping the fruits of enterprise arises from the fact that the use of substances in medicine cannot be patented unless the substances themselves are new. Mr. Pyman considers as a hypothetical case the courses of action open to the investigator who discovers that a previously described substance is efficient as a purgative:

1 He could market his substance under a registered name, in which case other manufacturers would speedily follow by marketing it under another name.

2 He could make use of it in disguise, as a constituent of a mixture of unclassified composition, but such procedure would prejudice his reputation in the eyes of the medical profession.

3 He could withhold his knowledge of the physiological activity of the known substance, and try to find some derivative or allied substance having similar physiological action and for the preparation of which a patent could be obtained.

The first course deprives the discoverer of any monopoly in his invention; the second and third prevent his discovery from becoming open or patent. From the manufacturer's point of view, then, an adequate system of monopoly patent is an incentive to research, to the marketing of products, and to the disclosure of processes. On the other hand, medical ethics prevent the patenting of drugs by registered medical practitioners, and this fact raises difficulties in connexion with new discoveries made by a team of research workers that includes a medical man.

Dedicated Patents.

Having recognized this difficulty Mr. Pyman proceeds to examine the proposal to effect a compromise between the interests of the manufacturer and the ethics of the medical profession by means of a system of dedicated patents. Such a system, he admits, may be very valuable in facilitating the patenting of inventions of the "biological" type, for it would provide medical research workers with a means of protecting their discoveries for the benefit of the nation without infringing their ethical code. But he doubts if the system is desirable in respect of inventions of the "chemical" type. Some possible national benefit might result from the proposal if it led the Medical Research Council to insist that important inventions made by persons in receipt of a public grant should be protected and the patents vested in the nation. At present it is left to the discretion of such persons to decide whether they shall patent their inventions or not, and there is the danger that if they prefer not to take out a patent foreign manufacturers may prepare their product and undersell manufacturers in this country. The case of thyroxine exemplifies yet another danger to national trade. Harington's decision not to patent his method of synthesizing thyroxine made it possible for foreign manufacturers to prepare this substance on equal terms with British manufacturers. A Swiss firm has recently taken out a British patent for effecting the conversion of Harington and Barger's azlactone into diiodothyronin in one operation instead of two, and while the particular advantage to be gained in this case may not be of much importance, it illustrates the folly from a national point of view of failing to protect an original discovery in the national interest and permitting foreign manufacturers to acquire a monopoly in an improvement of the invention. If Harington and Barger had been able to patent the synthesis of thyroxine in the national interest rather than in their own they might have been willing to do so, and in such case Mr. Pyman recognizes that dedicated patents might serve a useful purpose.

Objections to the Scheme.

A patent is in effect a reward for disclosure, and if the manufacturer is denied this he will keep his processes secret rather than broadcast them. What effect would the substitution of dedicated for monopoly patents in the case of chemical inventions have upon publication? In 1910, shortly after Dale and Laidlaw had shown that histamine has considerable physiological activity, Pyman devised and patented an improved and new synthesis of this base, and the process was published in 1911. What inducement, asks Pyman, would his employers have had to allow him to publish this new method if no patent, or a patent which they did not control themselves, could have been obtained in respect of his invention? Again, he and Carr, after extended and costly research, discovered that emetine was the mono-methyl ether of cephaeline, and, having patented the conversion of cephaeline into emetine by methylation, published their results in 1914. The partly synthetic emetine is identical with natural emetine, and the manufacturers could have put it on the market without disclosing any invention. If, therefore, no valid monopoly patent could have been granted in respect of the manufacture of emetine it would have been the obvious policy of the firm to work the process privately and to refuse

permission to Mr. Pyman and Dr. Carr to publish their results. Thus, according to Mr. Pyman, one result of substituting dedicated for monopoly patents in the case of chemical inventions will be to restrain the patenting of improved processes for the manufacture of known compounds, and consequently to hinder publication of the underlying scientific work.

A further difficulty arises from the fact that chemical inventions often proceed step by step, and if a manufacturer cannot obtain a monopoly patent for the preparation of a drug he will presumably try to protect some intermediate product essential for its synthesis. It might be argued that a patent for an intermediate would also be refused on the ground that it represented a step in the preparation of a drug, and served no other useful purpose; but this objection raises further difficulties, as many substances have been patented as intermediates for the preparation of both dyes and drugs. Mr. Pyman cites the two following examples. A patent has just been granted to the I.G. Farbenindustrie for the preparation of quinoline derivatives which "are useful therapeutically or as intermediates for the manufacture of therapeutic substances and dyestuffs." Again, Messrs. Boots and Dr. Marshall have recently patented the production of a new antiseptic from a new intermediate product which could also be used for the manufacture of a red dyestuff. Supposing that a monopoly patent for medical discoveries were denied, the firm could presumably patent the preparation of the new intermediate as a step in the process of manufacturing the dyestuff. These considerations, Mr. Pyman believes, illustrate some of the difficulties likely to arise from the substitution of dedicated for monopoly patents in the case of chemical inventions subserving medical purposes.

Nova et Vetera.

THE OLDEST MEDICAL ACT?

IN 1421, the ninth year of the reign of King Henry V, was passed what I believe is the oldest Medical Act in this country. I have consulted Halsbury's *Laws of England* and Chitty's *Statutes*, but there is no reference to this Act in either of them. In the Statutes of England, published by the Stationery Office, there is a mention of the Act, but nothing whatever is said of its repeal. It is possible that it may have been included in one of the many Statute Law Revision Bills, which are designed to clear the Statute Book of enactments which, though no longer in operation, have not been expressly repealed, but I have found nothing to support this possibility. If the statute is still law it appears to me that the position of the unqualified practitioner is not so secure as is generally thought.

Translated into more or less modern English the document reads as follows:

High and most mighty Prince, noble and worthy Lords Spiritual and Temporal, and worshipful Commons, for so much as a man hath three things to govern, that is to say soul, body, and worldly goods, the which ought and should be principally revealed by three sciences, which are divinity, physic and law, the soul by divinity, the body by physic, worldly goods by law, and this knowledge should be used and practised principally by the most learned men in the same sciences, and most approved in cases necessary to increase of virtue, long life, and goods of fortune, to the worship of God and common profit.

But worthy Sovereign it is known to your high discretion many unlearned and unapproved in the aforesaid science practise, and especially in physic, so that in this realm is every man, be he never so lewd, taking upon himself to practise and suffered to use it to great harm and slaughter of many men, wherein if no man practised therein but only learned men and approved sufficiently to be learned in art, philosophy, and physic, as is kept in other lands and realms, there should many men that dieth for default of help, live, and no man perish by ignorance.

Wherefore may it please your excellent wisdom that after your soul is of no help to your body for the causes aboveseid, to ordain and make in statute perpetually to be straightly used and kept, that no man of any manner, estate, degree, or condition practise physic from this time forward unless he has for a long time used the schools of physic, having sufficient testimonials in those degrees in the university in which he took his degree, under pain of long imprisonment and paying forty pounds to the king, and that no woman use the practice of physic under the same pain, and that the sheriffs of every shire make inquisition in their turns if there be any that forfeiteth against this statute under a reasonable pain, and then that they put this statute in execution without any favour under the same pain: also lest that they which are able to practise in physic are excluded from practice, the which be not graduated, may it please your high prudence to send writs to all the sheriffs of England that every practitioner in physic not graduated in the same science that wisheth to practise be within one of the universities of this land by a certain day that they that are able after true and straight examination be received to their degree, and that they that be not able to cease from practice until the time they are able and approved or to nevermore concern themselves with it, and that here also be set a convenient punishment.

Also, to take away the mischiefs and dangers that have long continued within this realm among the people, arising from those who have used the arts and practice of physic and surgery, pretending themselves to have been well and sufficiently instructed in the same arts, when in truth they have not, to the great deceit of the people. Now it is ordained and assented in this Parliament, that the Lords of the King's Council, for the time being, shall have power, by authority of the same Parliament, to appoint such order and punishment for those persons who shall hereafter intermeddle and use the practice of the said arts, not being skilful nor approved in them as to the same arts appertaineth, that is to say, those in physic by the universities, and the surgeons by matter of that art: and this, as it shall seem to the said Lords most convenient and necessary in the case, according to their good judgement and discretion, for the safety of the people.

The effect of this Act is to forbid the practice of medicine and surgery to all those who have not had a proper training, a condition of things which does not obtain at the present time in this country, when anyone, no matter how ignorant he may be, is able to exercise the profession of a doctor, provided he does not represent himself to be a duly qualified and registered practitioner.

It is interesting to note that of the forty-one statutes passed in the reign of Henry V six remain in operation either wholly or partially, including one regulating the visitation of hospitals, passed in 1414.

Since writing the above I have received the following note from the Editor of *The Justice of the Peace*:

"Although it has sometimes been referred to as a statute, the petition never, as such, seems to have been enacted. It does not appear in the *Chronological Table of All the Statutes* by authority; and certainly has not been formally repealed. The petition is endorsed as relegated to the Lords of the King's Council to make an ordinance to provide for the punishment of unrecognized practitioners; but no ordinance seems to have been promulgated."

L. A. PARRY, M.D., F.R.C.S.

IMPRESSIONS OF POST-GRADUATE WORK IN VIENNA.

[FROM A CORRESPONDENT.]

FOR many years the medical school of the University of Vienna enjoyed a reputation for the character of its work which was second to none in Europe; and during the last half-century this reputation has been enhanced by the genius of men who opened new avenues in the various fields of medical knowledge. One has only to recall the names of some of these leaders—Billroth in surgery, Israel in urology, Wertheim in gynaecology, Pirquet in tuberculosis, Freud in psychology—the list is unending—to realize how great has been the influence of the Vienna school on the progress of medical science and on the course of its development.

Organization.

Before 1914 post-graduate work in Vienna consisted chiefly of courses in German held under the authority of the University of Vienna; a working knowledge of German was essential to the student, though he was able occasionally to obtain individual teaching in the clinics by an English-speaking "docent." Since the war, however, graduate classes held in English are organized and con-

trolled by the American Medical Association of Vienna. By agreement with the medical faculty, private arrangements between student and teacher are no longer countenanced; the teaching of advanced medicine has been "rationalized," with the result, on the one hand, of a great increase in output, as shown by the large number of classes available, and, on the other, of a loss of elasticity and some commercialization of the teaching.

The courses are organized on the basis of at least three months' study; as, however, few English medical men, except perhaps the most recently graduated, can afford to leave their practices for so long a period, this method of organization prevents any large influx of British practitioners to the school. It is possible, however, for one who is energetic and perhaps a little catholic in choice of subjects to compress three months' classes into a period of five weeks. To take my own experience, my intention was to obtain post-graduate instruction in practical urology, in operative gynaecology, and in bone and joint surgery; to this end I joined classes in pathological, didactic, and clinical urology, and cystoscopic radiology, in operative and clinical gynaecology, in gastric surgery, in bone surgery and fractures, in local anaesthesia, and, as a sort of mental recreation, in rejuvenation. All this implied attendance at classes for eleven to twelve hours daily, and might appear likely to have resulted in acute mental indigestion; in fact, the variation in the character of the work—at one time listening to a lecture, at another operating on the cadaver, or dealing clinically with a patient—saved one from becoming stale. Operative surgery began at 7 a.m., classes finished at 8 p.m., at latest, and Saturday afternoons and Sundays were free.

The method of joining classes is as follows: the prospective student writes to the secretary of the American Medical Association of Vienna, Alserstrasse 9, Vienna, IX, who sends a handbook from which a certain amount of information is obtainable; he then notifies the American Medical Association of his intention to arrive about a certain date; and, having arrived, he reports to the cashier and joins the association. At this stage he would be well advised to address himself to the presiding genius who is in charge of forming the courses; this lady will order his destiny for the next few weeks; she will show him what courses are *opened*; *suggest* what classes *to* take and what to avoid; sandwich him into classes that have just started; steer him away from others that are waning; show him how to obtain money and food; and finally instruct him about suitable lodgings. When the prospective student goes back next day she has forgotten neither him nor his aims, and has further suggestions to make to meet his needs.

In starting a course in a given subject a lecturer posts a notice that a class limited to so many students will be opened on a certain date, each lesson lasting perhaps two hours. Operative classes are limited to two, clinical classes to four, other classes to ten; a few lecture courses are not limited in size. Most of the courses are filled and started within twenty-four hours of posting; but it is frequently possible to join a course of which one or two sessions only have been held; when one course finishes another begins within a few days. For the purpose of guiding students wishing to attend a series of classes "orientation men" are appointed in connexion with each course: as, however, these work on the basis that students will stay for three months I did not find them particularly helpful.

The success of the post-graduate courses in Vienna may be attributed to a number of causes: the work of the American Medical Association, which has organized and advertised the facilities; the wealth of clinical material available in the Allegemeiner Krankenhaus, a general hospital of nearly 6,000 beds, and in the Franz Joseph, the Wilhelmeiner, and the Pehan and other clinics; and the legal provision whereby all patients dying in hospital are available for post-mortem surgery. The actual courses differ somewhat from those in this country; incidentally, neither, in my opinion, is suitable for a graduate studying for a Fellowship. But while in this country post-graduate courses are arranged to suit the general practitioner, in Vienna they are particularized to special subjects which are differentiated from the general body of medicine. In Vienna the post-graduate student can obtain ample facilities for the study and practice of any subject in which he is particularly interested, without having to concern himself with other subjects which do not affect him.

There is no doubt that a period of post-graduate study affords a stimulus to the medical man and gives an added interest to the daily round. If, under the auspices of the British Medical Association, courses in specified subjects—for example, orthopaedics, urology, endocrinology, cardiology, or obstetrics—were organized in Vienna, Prague, or Budapest, there would be more incentive to the British doctor to avail himself of post-graduate opportunities in other countries. These courses should be for periods of three to four weeks, limited to a fixed number of students, and embrace didactic, clinical, and practical classes; it should be possible in the time to study two related subjects—for example, gynaecology and obstetrics. I am not suggesting post-graduate study abroad as a substitute for similar study in this country. Indeed, as an Edinburgh man I was gratified to hear from two experienced men, one an American and the other an Australian, who had both done post-graduate work in the United States, in Great Britain, and on the Continent, that the summer course of Edinburgh University was the most useful in the "didactic" style that they had encountered.

Cost of Post-Graduate Study.

Some idea of the cost of a visit to Vienna might be useful. Travelling by rail costs about £20 return; by air about £30. The advantage of the latter is that one can visit Berlin, Prague, Vienna, and Paris in the round trip, and I recommend it as giving a further interest to the holiday; it takes almost as long to reach Vienna, however, owing to the need for changes. The cost of rooms in Vienna is reasonable; in my pension the rate was about 10s. a day, and I was sufficiently comfortable and adequately fed. The expense of classes varies; during October, 1928, 392 courses were held at a cost of 12,000 dollars, say, about £6 10s. a course; but this sum is split up between the members of the class, so that if there are ten members the course costs 30s. each, but if only two, as in the operative classes, £3 5s. each. My own class fees, in view of the exceptionally large number of courses I joined, worked out at nearly £40 a month.

Social Life of Vienna.

The American Medical Association of Vienna does not neglect the social side, and organizes short tours and outings, dances and parties, to all of which Englishmen are invited. There are two golf courses, and facilities for tennis and bathing. To the amateur student of social conditions the state of Austria is of interest. The absence of the old aristocracy, the depression of the professional classes, the existence of severe poverty, and the constant political struggle between the highly socialistic urban population and the individualistic rural party, have converted Vienna from the gayest capital in Europe to the quietest. I was told that the consultant's fee was about five shillings, while £15 was a big operation fee: naturally more is expected from a foreigner. The financial difficulties of many medical men are almost unbelievable; pre-war investments are almost worthless; owing to the limitation of rentals to one-tenth the pre-war rent property is a burden to the owner. On the other hand, the enormous blocks of flats built by the Government to replace slum properties are visible token of the effort made to overcome the problem of reasonably housing the working classes. There was no obvious sign that these excellent flats were becoming degraded owing to inability of the slum dweller to adapt himself to his new environment.

Whether the Vienna of to-day maintains its former greatness as a medical centre may be doubted; the result of the war, the relative poverty of the professional classes, and the reduction of Austria from its old position to a republic of six million individuals have had a depressing effect on the mental attitudes of the intelligentsia. The leaders of medical thought in Vienna, it seems to me, were influenced by the fear that with the passing of political greatness Vienna had lost importance as a cultural centre.

British Medical Journal.

SATURDAY, MAY 24TH, 1930.

LABORATORY METHODS FOR THE DIAGNOSIS OF PREGNANCY.

FOR several reasons, and in a variety of instances, it is highly desirable that a definite diagnosis of pregnancy should be made as soon as possible after the menstrual cycle has become interrupted. It is equally desirable that the method adopted should not be unpleasant to patient or physician, but simple, capable of being used by the geographically isolated general practitioner, cheap in time and money, and, of course, reliable. Any method which does not fulfil these conditions can never be regarded as being entirely satisfactory. The Abderhalden test, for which the serum of the woman is brought into contact with specially prepared coagulated placenta, can be applied only by the physician who is highly trained in laboratory methods. Changes in sugar tolerance and in the amount of acetone bodies are certainly associated with pregnancy, but not solely with this condition, and therefore a satisfactory pregnancy diagnosis test based on such changes cannot be evolved. The local reaction which follows the subcutaneous injection of posterior pituitary extract or of anterior lobe hormone has been held to be diagnostic of the non-existence of pregnancy, but since this test has not been sufficiently studied its value cannot as yet be assessed.

The tests which are now in vogue are those based on the fact that in the urine of the human female are to be found considerable quantities of those hormones which are concerned with the maintenance of pregnancy. One of these, which invokes oestrous changes in the female mouse, is known as "folliculin," "oestrin," or "alpha hormone," etc. In the urine of a pregnant woman there are also to be found those pituitary derivatives which regulate ovarian function, and thus control the elaboration of the ovarian hormones. One of the tests, which has been elaborated particularly in America, depends upon the presence of oestrin in the urine. It is a quantitative test, for this hormone is to be found in the urine in cases where pregnancy does not exist, but the necessary biological assay is very difficult. The test has not been developed to any great extent for the reason that the diagnosis of pregnancy through the recognition of the existence of anterior pituitary derivatives in the urine can be made much more easily. These hormones occur also in the urine of non-pregnant individuals, but their concentration is far greater in the urine of a pregnant woman than in that of a woman who is not pregnant. This difference is sufficient to permit a very specific test to be carried out, for when that concentration which is reached during early pregnancy is present, the effect upon the immature mouse ovary of injections of urine containing these substances is such as to produce demonstrable and characteristic morphological changes therein. This effect upon the mouse ovary was noted by Zondek and Aschheim, and has been used by these authors as the basis for the well-known pregnancy test which is known by their names.

The application of this test on a large scale, as has been done, for example, in the Pregnancy Diagnosis Station attached to the Animal Genetics Department of the University of Edinburgh, has shown that only very few conditions other than pregnancy are associated with a significantly great excretion of these hormonic factors. From this work one fact of considerable interest has emerged, and that is that the urine from cases of malignant tumour can also give a positive Aschheim-Zondek reaction; but since the percentage of tumour cases in any population examined for pregnancy is likely to be small, even though malignancy can give the same reaction as does pregnancy, this fact does not destroy the usefulness of the test in the diagnosis of the latter condition. It is at the present time the most satisfactory test available, but it is far from being ideal, for it requires, if it is to be of any real service to the medical profession, that there shall be special centres established where large stocks of mice are maintained and where skilled service is available. Though the effects upon the mouse ovary are so very characteristic and so easily detectable, and though it is possible for a general practitioner who possesses a certificate to maintain a small stock of mice, it seems most unlikely that the Aschheim-Zondek test will ever become one which the general practitioner can be expected to carry out himself.

The search for the ideal test is being continued. It seemed that perhaps Voge, in his suggestion of a bromine test (*British Medical Journal*, November 2nd, 1929, p. 829), had devised an entirely satisfactory method for the detection in the urine of pregnant women of compounds of the beta-iminazoyl type, and thereby of the condition of pregnancy. He obtained results which compared exceedingly favourably with those secured in the same laboratory by means of the Aschheim-Zondek test; but further experimentation has shown that, after all, this test will not serve, for Dr. Gladys Dodds, in our present issue (p. 948), shows that in a series of cases examined by her there was some 25 per cent. of error among individuals known to be pregnant, and 13 per cent. among those known to be not pregnant.

It would appear that rather than to extend experimentation of an empirical kind it would be better to attract the attention of those who seek to devise a pregnancy diagnosis test towards an exact chemical analysis of the urines of different groups—for example, pregnant, non-pregnant, and cases of malignant tumour—in order that they might determine what differences in respect of chemical groupings distinguish them. If oestrin is present in a urine, then, as has been suggested, this might contain the hydroxyl grouping, and if this were so it could easily be detected by appropriate chemical means. If histidine-like compounds are characteristic of pregnancy, then the presence of these could be demonstrated by methods involving the production of azo-dyes. These possibilities should certainly be explored. The time has come when the attention of the organic chemist should be drawn to the accomplishments of the physiologist, for it would appear that without the help of the former the search of the latter for the ideal pregnancy diagnosis test cannot be completely successful.

FILTERABLE VIRUSES.

THE many activities of the Medical Research Council in the field of filterable viruses, and parallel activities of other bodies and individuals, both in this country and abroad, testify to the determined efforts now being made to get an understanding of the nature of this mysterious group of disease agents. At this juncture it may be fitting to review the work that has been done, taking stock of successes and failures, and estimating the gains to date. Progress has been slow, but real advance has been made is undeniable. For an example may be taken the problem of cultivation, the solution of which will open up the way to more rapid advances in the future. Until comparatively recently viruses could be cultivated only in the tissues of the living animal; but Carrel, by showing that the virus of vaccinia could be cultured along with living tissue outside the animal body, made a very definite advance. Even though this method of cultivation has told us little or nothing about the nature of viruses it has at any rate brought cultivation more under control, and has been employed with considerable success by Andrewes and Rivers in studying the problems of immunity. The Maitlands carried the question a stage further by finding an extremely simple method of growing viruses with living tissue, but here again the presence of living cells appeared essential. Are these viruses such highly specialized intracellular parasites that their growth requirements can only be supplied by living cells? Recent work by Mackenfuss and Rivers would appear to answer this question in the negative, for they have been able to show that vaccinia virus will live and possibly multiply when shut off from the living tissue by a collodion membrane. This may, of course, only be an example of survival and not of multiplication, a point which will be readily cleared up by further work, but the line of attack is ingenious and of great promise.

The question of the nature of the immunity to virus diseases has received considerable attention. Levaditi and his school have maintained that immunity to filterable viruses is largely, if not wholly, a tissue immunity in which the humours play little or no part. The work of Gordon, Ledingham, and Andrewes with vaccinia virus, and of Bedson, Zinsser, and others with the virus of herpes, has not supported this contention, and it may be concluded that in these diseases, as in those of bacterial origin, the two factors—humours and cells—work together to bring about the immune state. While however, there seems some unanimity of opinion about the importance of viral antibodies, the way in which they act has been a matter of acute controversy. The earlier work of Andrewes suggested that union between vaccinia virus and its antibody did not occur but his more recent experiments show that union does take place, though only slowly—a finding more in keeping with the work of Wilson Smith with vaccinia and herpes virus and of Bedson with the latter virus. The recent experimental investigations carried out at the London Hospital, which have gone far to establish the view that psittacosis is caused by a filterable virus—a view borne out by work in America and Germany—have added even greater interest to the study of this group of viruses, not only because psittacosis is a disease of birds to which man is susceptible, but principally because it would appear to be an example of a virus pneumonia. It has been thought for some time that influenza has a filterable virus as its exciting cause, and the work on psittacosis lends colour to this view. The common cold is another disease which has been suspected of having a virus origin, and the investigations of Dochez and his colleagues in the States would appear to go a considerable way towards confirming this hypothesis.

In conclusion, we may refer to the work on prophylactic immunization against virus disease with inactive vaccines. This method has been exploited for some years in connexion with rabies, but research along these lines was given a fresh impetus when it was demonstrated independently in France and in this country that the virus of foot-and-mouth disease could be rendered inactive by means of formalin and still retain its antigenic power. The same has been found true for other viruses, among them those of distemper, fowl plague, and yellow fever, and by successive injections of formolized virus and living virus prophylactic immunization against distemper has been practised with considerable success. It must not be concluded, however, that similar methods will necessarily be effective in all virus diseases. Obviously, such conditions as the common cold, in which one attack is not followed by a stable immunity, will not lend themselves to prophylactic immunization; and in those diseases where a solid immunity does ensue preventive measures of this kind will be impracticable, at any rate on a large scale, until the problem of growing filterable viruses has been solved. An enormous amount of work remains to be done; problems confront us which appear almost insoluble; but, as the Medical Research Council points out,[1] these problems are relatively no more difficult than those which presented themselves to bacteriological investigators in the days before Pasteur and Koch. Material progress has been made in which research workers in this country have played no small part, and we feel that ultimate success, if not imminent, is yet within sight.

BRUCELLA INFECTIONS AND PUBLIC HEALTH.

Bang's disease, or epizoötic abortion, is a well-known disease of cattle in northern latitudes. It has been recognized for many years in Britain, where it is regarded as one of the major sources of loss to stock owners—second in importance only to bovine tuberculosis. In the United States it is estimated that 20 per cent. of the cows are infected, causing an annual loss of about 175 million dollars. There are no comparable figures for this country, but there is no doubt that here, too, the annual loss must be enormous. Until recently the condition has been associated mainly with abortion in pregnant cows, and the fact that bacilli were frequently excreted in the milk was regarded as of little significance, except in so far as the calf was concerned. Nowadays, of course, it is recognized that abortion is by no means a regular symptom of an infected cow, nor is abortion in cattle always due to Bang's organism. The fact, too, that the causal organism of undulant fever in Malta was described as a micrococcus, while the organism of contagious abortion was obviously a bacillus, prevented an earlier recognition of the relation between these two conditions. During the past few years in America and in Europe extensive research has taken place on these two diseases, and it is now generally accepted that the causal organisms of both are merely varieties of the same bacillus to which the generic name Brucella has been given. Bacteriologists recognize a variety of strains, and there is as yet no general decision as to their exact status. Three main groups have been differentiated: a caprine group which includes *M. melitensis* of Bruce, mainly subtropical in its distribution; a bovine group which includes *Br. abortus* of Bang, mainly distributed throughout the temperate zones; and a porcine group, which appears to have a distribution

[1] Report of the Medical Research Council for the year 1928-29. H.M. Stationery Office. 1930. Cmd. 3656. 3s. net.

similar to that of the bovine. The names do not imply that these groups are confined to goats, cattle, and pigs respectively; only that they seem to find their optimum hosts in these animals. All three can be transmitted to cattle. Many of the suppurative conditions in horses have recently been found to be primarily caused by Brucella (though epizoötic equine abortion is not due to this group of bacteria); even birds have been experimentally infected; and natural infections have been recorded from domestic poultry in the United States. All the varieties are transmissible to man, but in different degree. The caprine varieties are the more virulent, the porcine the easiest to transmit. Milk is apparently the main source of human infection, but a number of cases are due to actual contact with infected animals. In recent years the incidence of Brucella infection in man has enormously increased, and recent estimates in America place the rate of infection as between 1 and 10 per cent. of the total population. Such infection does not necessarily connote disease; or at least disease sufficiently serious to attract the attention of the physician. But not infrequently Brucella does produce disease, which though of low mortality may cause a long illness and an extensive and protracted convalescence. The symptoms are very variable and may simulate those of tuberculosis, endocarditis, malaria, arthritis, influenza, typhoid fever, and so on. Abortion is very uncommon in the human subject, though cases are on record. Children under 5 are seldom affected, and the highest incidence of the disease is found in young adult males. A great deal of attention has lately been given to this disease in America, and it has been found that the human infection is much more common than had been suspected. While this apparent increase may in part be due to improved methods of diagnosis, it is suggested that it may also be due to the confidence placed in tuberculin testing of cattle. The Americans are great milk drinkers; and tubercle-free milk is generally regarded as clean milk, though the terms are by no means synonymous. In many places pasteurized milk has been replaced by raw milk certified free from tuberculosis, and a definite safeguard against Brucella infections has in this way been removed. Several localities have prohibited the sale of unpasteurized milk, unless it is from cattle certified free from Brucella infections as well as from tuberculosis. But there is no doubt that at the present stage the surest safeguard is pasteurization. There is, it is true, a slight loss of vitamins, but in a balanced diet this loss is negligible. Pasteurization of milk, of course, must not be allowed to become an excuse for the production of dirty milk by the dairyman. Some of the American States are building up Brucella-free herds in a manner analogous to that employed in building up tubercle-free herds. All cattle are tested, reactors are segregated, and their milk is used only after it has been pasteurized. The non-reactors and all calves are kept entirely apart from the reactors, and no physical contact is permitted. All new stock is tested and only introduced if free from infection. In this way a Brucella-free herd can be established within a very few years. The tests employed have generally been serological—agglutination or complement fixation—but recently there has been introduced an intradermal test by means of "abortin"—a substance similar to tuberculin and mallein, and employed in much the same way. The intradermal test is simpler and less expensive than the serological, and apparently it gives even more accurate results. It is of interest to remember that abortin was first prepared by M'Fadyean and Stockman in this country twenty years ago. A number of Continental countries have made the bovine disease notifiable, but, so far, Britain has regarded the Brucella infections as of little importance. A number of cases have been reported, however, and there is little doubt that once the facts are generally known many more will be found to exist. Fortunately, the disease is easily controllable—much more so than bovine tuberculosis—and there are no grounds for alarm. Pasteurization alone is sufficient to render milk safe, and concerted action, as public opinion is influenced, could quite easily eliminate Brucella infections from our herds.

ROYAL SOCIETY CONVERSAZIONE.

THE spring conversazione of the Royal Society was held on May 14th in the Society's rooms at Burlington House, the guests being received by the president, Sir Ernest Rutherford, O.M. The exhibits on this occasion were fewer than usual. A demonstration which attracted considerable attention was one arranged by Captain S. R. Douglas, *F.R.S., and Dr. Wilson Smith to record the results obtained* by Miss J. Marchal, who has been investigating at the National Institute of Medical Research a hitherto undescribed virus disease of mice termed "infectious ectromelia." The histology of this condition was illustrated by beautifully stained microscopical slides, which revealed the occurrence of cytoplastic inclusion bodies in the epithelial cells of the skin of the feet, and in the secreting cells of the pancreas and salivary glands. Necrosis of certain mesoblastic tissues, such as the liver and spleen, was found in fatal cases. The disease begins with swelling, usually of one hind foot; this is followed by gangrene and separation of the affected portion of the limb. The death rate among the infected stock was high, and post-mortem examination brought to light changes in the liver and spleen, even in the absence of external lesions. Miss Marchal attributes the condition to a filter-passing organism. A somewhat similar exhibit was that of Dr. J. Henderson Smith, from the Rothamsted Experimental Station, who displayed specimens of virus disease in tomatoes. The example shown included the occurrence of the same virus in different host plants; different viruses in the same host plant; the combination of two viruses in one plant; and the intracellular inclusions which characterize many virus diseases in animals, as well as in plants. A demonstration was given of the fact that the movement of the virus within the plant does not normally occur in the water or transpiration stream, nor across dead tissues. An illustration was given of the way in which the insects which are responsible in nature for the spread of such virus diseases were experimentally bred in the laboratory. A beautiful series of illuminated coloured transparent photographs of the natural vegetation of South Africa was provided by Dr. and Mrs. Pole Evans; these showed flower-bedecked panoramas of grassland, forest, and desert areas. Dr. Pole Evans, who took the photographs, travelled by motor car and van through the Cape, Natal, Swaziland, Zululand, the Orange Free State, and the Transvaal. The National Physical Laboratory showed an apparatus for transmitting and receiving radio wave-lengths of 4 to 10 metres; the reception and recording of signals from the Orfordness *rotating wireless beacon*; the frequency analysis of a modulated continuous oscillation; friction and wear tests of pivots and jewels; and a hygrometer for use in ship holds. A recording microphotometer was exhibited jointly by the Solar Physics Observatory, Cambridge, and the Cambridge Instrument Company, while the *Cambridge* Low Temperature Station illustrated the formation of methaemoglobin in red muscle, and explained how acetaldehyde could be used to control the wastage due to fungi attacking certain fruits. Mr. L. S. B. Leakey showed the Leakey-Harper drawing machine, which has been designed to facilitate the accurate detailed representation of human skulls; with its aid drawings can be made very speedily, and the machine can also be used for making drawings of fossil pottery, and Palaeolithic instruments. Mr. R. S. Whipple showed an early Italian globe, said to have been engra

by Paolo de Furlani, a well-known engraver and seller of maps in Venice in the second half of the sixteenth century. Photographs of the new planet were provided by the Radcliffe Observatory, Oxford. The zoological department of the British Museum supplied specimens of a Nigerian frog in and in which an oligochaete worm had been found to be parasitic. The oligochaetes are extremely rare as internal parasites, and it is believed that this is only the second case which has been definitely authenticated. Professor D. M. S. Watson, F.R.S., gave a lecture illustrated by lantern slides on the flight of pterodactyls. He showed how the osseous structure and arrangements of the skeleton varied according to the size of these reptiles; weight saving was brought to an extreme degree of effectiveness, and the articulation between the various bones had the perfection of the most ingenious machinery. Important information had thus become available as to the mode of life and habits of the pterodactyls, and, moreover, study of the way in which they left the ground and rose into the air had also a practical interest in that suggestions were deducible for improving the design of aeroplanes.

JUBILEE OF THE BRITISH DENTAL ASSOCIATION.

THE British Dental Association, which holds its annual meeting in London next week (May 27th to 31st), is celebrating the fiftieth anniversary of its incorporation. Although there were several dental societies in existence before the passing of the Dentists Act, 1878, most of them were purely scientific bodies. In consequence of that Act there arose the need for an association—to quote from the memorandum and articles—for "the promotion of the dental and allied sciences and the maintenance of the honour and interests of the dental profession by means of periodical meetings, by the publication of a journal, by the grant of money for the promotion of dental science, by the maintenance of the spirit and provisions of the Dentists Act, and last, but not least in importance, by the encouragement of a dental benevolent fund for the relief of decayed members of the profession." The Dental Reform Committee, after its preparatory work had resulted in the passing of the Act, resolved itself into the representative board of the British Dental Association, which was incorporated in 1880. The earlier Act proved a disappointment in some respects, but the association persevered until, through its labour and patience, the Dentists Act, 1921, came above the horizon. In many directions the association, which now covers Great Britain and Northern Ireland with sixteen branches, has done notable service for the profession and the public. The jubilee meetings will take place at the Hotel Great Central, in London; after an opening address by the Minister of Health, the retiring president, Mr. Malcolm Knott of Birmingham, will deliver his valedictory speech, and the new president, Mr. Norman Bennett of London, will be inducted. It is proposed to elect a number of honorary members, including distinguished representatives of the dental profession in Vienna, Berlin, Paris, Stockholm, and in each of the Dominions. A conference is to be held between the council of the association and the Dominion and Colonial representatives, on means for promoting a closer union between the dental associations of the Empire. Various scientific discussions are to be held, including one on the relative advantages and disadvantages of the modern materials used as bases in prosthetic dentistry; there is also a very full programme of table demonstrations at headquarters, of clinical demonstrations at various hospitals, and of visits to industrial clinics and London County Council dental treatment centres. A museum illustrating the history of the Dental Association during the last fifty years will be open, together with the usual trade exhibition. The social side of the meeting is excellently arranged, and includes receptions at the London Guildhall and at the Royal College of Surgeons.

THE STAFFING OF A COTTAGE HOSPITAL.

In this week's *Supplement* will be found a detailed account of the steps by which an unfortunate and, we are glad to think, unusual impasse has been reached in connexion with the staffing of a cottage hospital in North Wales. Very briefly the position is as follows: The Towyn Cottage Hospital, staffed in 1927 by the open method, has been converted into an institution with a closed staff of three general practitioners, representing two local practices, chosen by the lay committee of management according to rules which are known to have been materially altered by that committee on at least two occasions at the very time when an application for appointment to the staff fell to be considered. These changes in the rules have had the effect of excluding from the staff a local practitioner who, in the expressed opinion of the local Division of the British Medical Association, is in every way fitted to serve the hospital and was qualified for such service under the original rules at the time of his first application and later under the rules as modified at that date. The alterations in the rules have been made under a general discretionary power of the committee, the existence of which power is not questioned. We speak of this committee as a lay body because we understand that the medical staff, who are members of it, have no vote; but we cannot ignore the fact that the medical staff have possessed throughout this affair a more effective power than that of a minority vote. It is, to say the least, unfortunate that the local Division of the Association, in its efforts to secure justice for a medical man who, by all accounts, has been most unfairly treated, should have failed to secure from its members on the staff of the hospital the support which it might reasonably have expected to receive and which would have made a speedy settlement possible without undue publicity. The policy of the British Medical Association favours the open method of staffing for such hospitals as this, subject always to adequate safeguards. The subscribers to the hospital, who are fully seised of the position by the action of the local Division, have now to decide on the maintenance or modification of this policy. They have also to decide two simpler issues: first, whether they are prepared to leave the administration of their affairs in the hands of a body which has used its powers to exclude from the full benefits of the hospital service a number of those who desire to be attended by their own doctors, and has subjected an individual practitioner to grave injustice; and, secondly, whether they wish local medical opinion to be consulted or to be ignored in the selection of their medical staff.

HEALTH OF MAORI SCHOOL CHILDREN.

A REPORT by Dr. H. B. Turbott, medical officer of health, Gisborne, New Zealand, on the comparative health of the Maori and pakeha should go far to dispel any pessimism that may still prevail about the future of the Maori people. During the latter half of 1928, to find out what truth there was in various persistent statements about the dangerous health conditions among Maoris, Dr. Turbott made a careful examination of 1,423 Maori children in his district, and compared their health and physique with those of a group of 1,569 pakeha children. In his report, which is published as an appendix to the report of the Director-General of Health, New Zealand, for the year ended March 31st, 1929, he states the results of his investigation as far as possible in figures, giving in relation to each condition the incidence rate per 1,000 of children seen. Anaemia and heart trouble were more frequent among the white children, the incidence per 1,000 of the former being Maori 1.40, and white 11.47; and of the latter, Maori 4.91, and white 6.37. Respiratory disease, though small in amount, was more prevalent in the Maori group. Of Maori children 30.82 per 1,000 were considered to have unhealthy chests, 5.62 being probably tuberculous; of white

children 12.74 were weak-chested, but none were held to be suffering from pulmonary tuberculosis. Associated with this respiratory weakness among Maoris was a great deal of indigency, with its attendant evils of poor diet and bad housing. Some of the children, moreover, had to work very hard, especially where dairy farming was being undertaken, and Dr. Turbott suggests that in the circumstances it would not have been surprising if even more children had been found to be infected. The Maori physique proved, on the whole, to be better than the white; in nutrition, in posture, and freedom from deformities of the trunk and chest the Maori child had a decided advantage. Pediculosis was all too prevalent among the Maori, dissemination being facilitated by the crowded housing conditions, and, above all, by the common practice of sleeping five or six in one bed; and for similar reasons infectious skin conditions—for example, scabies and impetigo—were found to affect the Maori more than the white child. The latter, on the other hand, was found to suffer more commonly than the Maori from eczema, seborrhœa, ichthyosis, and ringworm. Perfect sets of teeth were found in 246.65 per 1,000 Maori children, and in only 50.98 white children, but Dr. Turbott points out that the more closely the Maori copies the pakeha diet the more quickly does his dental superiority vanish. Enlarged tonsils, enlarged cervical glands, goitre, phimosis, and eye troubles—all these were more prevalent in the group of white children than in the Maori group. Hernia, vulvo-vaginitis, and flat-foot were more common among the Maoris. The total number of children in each group was admittedly small, but Dr. Turbott's findings would seem to indicate that the sturdiness of the old Maori warrior has been handed on to his descendants. In health and physique they compare favourably with the pakeha, and it is noteworthy that where they are at a disadvantage—as, for example, in respiratory disease—preventive medicine might be expected to bring them up to the level of their white friends.

CHINA AND THE LEAGUE OF NATIONS HEALTH COMMITTEE.

IN September, 1929, the Ministry of Foreign Affairs in the Nanking Government of the Chinese Republic addressed a proposal to the Secretary-General of the League of Nations for collaboration with the League's Health Committee. China asked for advice and assistance with regard to the following points: (1) the formation of an efficient technical headquarters staff for the study of essential problems of public health in selected areas and for practical application in the field, as well as for the training of public health personnel and auxiliary staff; (2) the setting up of a network of indispensable medical and public health institutions in two or three areas on a sufficiently wide scale to serve as a nation-wide training field, yet limited in scope to the possibilities of a thorough and effective realization; (3) the intensive study, jointly with the Ministry of Education, of the existing facilities for medical education and of the programme of reform for the immediate future; (4) the gradual establishment of a national quarantine and epidemic diseases prevention bureau; and (5) the initiation of control, on a co-operative basis, of cholera and smallpox in the Shanghai area. The Chinese Government has now a Ministry of Health, at the head of which is a small group of Chinese foreign-educated medical men under Dr. J. Heng Liu. This Ministry is both active and ambitious; it desires to see China taking her place among other countries in attaining a modern standard of public health. The technical activities of the League's Health Committee have steadily developed, and it is now in a position to afford advice on the solution of internal problems of organization and construction on a world-wide basis without the risk of incurring any extraneous obligations or conditions. The White Paper which we have received from Geneva shows to what extent the League responded to the Chinese Government's invitation. Dr. Madsen, president of the Health Committee, instructed the medical director, Dr. Rajchman, and Dr. Bondreau to proceed to China in order to discuss with the local competent authorities a detailed project for consideration by the Health Committee. Their report, which does not represent anything more than notes on the proposals and observation on the centres they were asked to visit, is nevertheless a very good and industrious survey of medical conditions in China. It deals with the modern as well as the empirical systems of medicine, the hospitals, and public health work in China, and it touches upon the inadequacies and difficulties of medical education. For the past fifty years foreign medical men, mostly missionaries, have laboured in China to establish colleges and hospitals and to educate Chinese students in Western medicine. It has been an uphill struggle, latterly much interfered with by political troubles, and the results have been only moderately satisfactory. The great majority of practitioners are returned students from America and Europe who, as the report points out, are split into a number of groups according to the country in which their training was received. There is not as yet a general medical council, or any real merging of the groups, and until China can accomplish this she cannot be said to have a national medical profession. It would seem to us that this appeal to the League of Nations is somewhat premature, for there yet remains much spade work to be done in establishing medical education in national colleges in order to yield enough graduates to take up and carry on the reforms which are now desired. A short visit under Chinese guidance to such an immense country cannot do more than scratch the surface, and we are glad to note that the League has arranged for Dr. Park to proceed to China and give further study "to the possibilities of the satisfactory applications of the provisions of the International Sanitary Convention of 1926." The visit of the Commission and the presence of Dr. Park will help to stimulate Chinese medical leaders in the founding and extension of medical education. The setting up of a modern public health service will require a much larger number of graduates than is at present available, for it is from their ranks that the service will have to recruit its officers. Meanwhile we can only congratulate the League of Nations Health Committee on its energetic response to China's appeal for help. The report will no doubt receive serious consideration, and, if so, it will give an impetus to the task of placing modern medicine in China on a sounder basis.

RESEARCH FELLOWSHIPS IN TUBERCULOSIS.

THE first award of the Dorothy Temple Cross Research Fellowships in Tuberculosis, provided from a fund established by a recent benefaction, will be made by the Medical Research Council in July, for the academic year beginning October 1st, 1930. Applications should be lodged with the Council not later than June 30th, 1930. The object of the Fellowships, as defined in the trust deed, is to give special opportunities for study and research to persons "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms." Candidates must be British subjects with suitable medical, veterinary, or scientific qualifications. They must also be able to produce satisfactory evidence of their ability to make good use of the opportunities offered. The Fellowships will preferably be awarded to candidates who wish to conduct their studies or inquiries outside the borders of Great Britain. They will, as a rule, be awarded for one year, but in special cases may be renewed. The value of the Fellowships awarded will depend in each case upon the standing and qualifications of the candidate, but will not be less than £300 per annum, with travelling expenses in addition. It is also hoped to award one senior Fellowship of considerably greater value,

and with good prospect of renewal for a further period, to a well-qualified candidate wishing to undertake intensive investigation into some special problem of tuberculosis, whether in a temperate or a tropical climate. Further particulars and forms of application are obtainable from the secretary, Medical Research Council, 38, Old Queen Street, Westminster, S.W.1.

ACCIDENTS TO HYPODERMIC NEEDLES.

THE frequency with which the London and Counties Medical Protection Society is applied to by its members, in cases of hypodermic needles breaking during the administration of local anaesthetics, has prompted the council of the society to circulate recommendations on the use of hypodermic needles so as to lessen the incidence of this accident, or, should it occur, to give good ground for successfully contesting any claims arising therefrom. The recommendations that follow have been drawn up by the council after consultation with expert metallurgists. A new needle should be used for every case. Needles should never be "flamed" in order to sterilize them, as this may profoundly alter the temper of the needles and render them very brittle. Needles nearly always break at the point of entry into the holder, and a short holder should therefore be used, so that if fracture occurs at this point a large part of the needle will remain in the tissues and so be the more readily found and removed. Needles, unless of stainless steel, should not be kept in watery sterilizing solutions, which may corrode and weaken them, even though such damage may not be visible to the naked eye. When a needle breaks, the society should be advised immediately, whether a claim is made or not. In such cases the make of the needle should be stated and, when possible, both of the broken parts should be sent to the secretary. Any untoward experiences with any make of needle should be recorded. In the event of more than one breakage, not only should the two parts of the broken needles be forwarded, but also the remaining contents of that tube of needles. Lastly, members of the society are advised that owing to the difficulty of tempering so small an article as a carbon steel needle to the exact degree required, an unnecessary risk is run in using them; better and more constant results are obtainable from needles made of alloy steels (such as stainless steel) which do not require subsequent heat treatment, and are, generally speaking, far more flexible than those made of carbon steel.

ANNUAL REPORT OF THE ROSS INSTITUTE.

IN a brief notice of the annual meeting of the Ross Institute last July reference was made (*Journal*, July 20th, p. 129) to the malaria expedition to India and Ceylon which was undertaken by Sir Malcolm Watson and Major Lockwood Stevens in 1928–29; some details of the expedition, and of the developments which followed it, appear in the annual report of the Institute for the twelve months ending December 31st, 1929. In consequence of the adoption of antilarval measures in certain iron ore mines in Bihar and Orissa there has been a marked reduction there in the incidence of malaria, and similar improvement is recorded also in Assam. Another expedition, consisting of Sir William Simpson, Dr. Dalzell, and Mr. C. R. Harrison, visited Northern Rhodesia last autumn, and paid special attention to housing, general sanitary measures, and the scientific aspects of the malaria problem. Sir Malcolm Watson is now in Rhodesia on a tour of inspection, studying more especially the mines and some local conditions which affect the prevalence of this disease. Towards the end of last year two courses of instruction for planters and others engaged in the management of estates in the Tropics were held at the Institute, and facilities were provided throughout 1929 for work by medical practitioners. The importance of propaganda has always been recognized by the Institute, and Dr. Cuthbert Christy's paper on malaria prevention, which was originally published in 1917 for the education of laymen, has now been brought up to date, and is being distributed to residents in the Tropics. The support given to research work by the Institute is illustrated by the publication in an appendix to the annual report of a summary by Dr. A. Shaw-Mackenzie of a study of the diagnosis and treatment of cancer. Other subjects investigated during the year under review include certain diseases due to fungi, colitis, the symbiotic gas fermentation phenomenon, and the effects of carbohydrates on the growth of intestinal bacteria. A list of Sir Ronald Ross's publications during 1929–30 is printed as an appendix. The number of in-patients treated during the year at the Institute was sixty-eight, many having serious and chronic tropical diseases, which entailed long periods of residence. The total receipts from donations and subscriptions show an increase of about £2,500, principally due to a gift of £1,000 by the Nizam of Hyderabad and to contributions received through the Bengal Chamber of Commerce. An appeal is made for £30,000 needed to permit extension of the hospital accommodation, the library, and laboratories, and also for £250,000 for an endowment fund.

THE Royal College of Physicians of Edinburgh proposes to celebrate on St. Andrew's Day, 1931, the 250th anniversary of its foundation. It was on November 29th, 1681, that the Great Seal was appended to the Royal Charter incorporating the College, granted by King Charles II.

THE George Alexander Gibson Memorial Lecture will be delivered in the hall of the Royal College of Physicians of Edinburgh on May 27th and 28th, at 5 o'clock, by William Sydney Thayer, M.D., LL.D., Emeritus Professor of Medicine, Johns Hopkins University, Baltimore. Professor Thayer has chosen "Endocarditis" as his subject.

THE annual general meeting of the Research Defence Society will be held at the House of the Medical Society of London (11, Chandos Street, Cavendish Square, W.), on Tuesday, June 3rd, at 3.15 o'clock. The chair will be taken by the president, Lord Lamington, and Mrs. Edward Mellanby will deliver a lantern lecture on "Diet and dental disease: What we have learned from animal experiments," being the fourth Stephen Paget Memorial Lecture.

IN the issue of *Science* dated May 2nd (p. 453) appears a statement that Dr. E. A. Doisy and his co-workers, Clement D. Veler and Sidney A. Thayer, have assigned to St. Louis University patent rights in connexion with the crystalline ovarian hormone, the isolation of which Doisy announced at the thirteenth annual physiological congress in August, 1929. The terms of the donation provide that the eventual income, if any, is to be used entirely for the prosecution of research in the School of Medicine, the administration of the funds to be subject to the general financial policy of the university. Arrangements have been made whereby one manufacturing company has been given an exclusive licence to operate the patent for eighteen months, but after this period the patent rights will not be restricted, and the licence to manufacture and distribute the product may be given to other firms under the same conditions as those imposed upon the first licensee. The Committee on Grants for Research recently formed at St. Louis University has provided that all developments in the preparation of the crystalline hormone, in its clinical applications, and in the discovery of its properties, must be shared alike by the university on the one hand, and the licensee or licensees on the other. The Council on Chemistry and Pharmacy of the American Medical Association has approved of the name "theelin" for crystalline ovarian hormone prepared according to Doisy's process.

BRITISH EMPIRE RED CROSS CONFERENCE.

PERFECTING PEACE-TIME ORGANIZATION.

A *British Empire Red Cross Conference* was held in London from May 19th to 24th, its purpose being to examine the experience of the last ten years, during which the British Red Cross Society, under its supplemental charter, has extended its work from the relief of suffering caused by war to relief of suffering and improvement of health in time of peace. All the Red Cross organizations in the Dominions were represented, as were also the Central Council Branches in this country, various kindred organizations, and the International Red Cross. At the opening meeting, held at St. James's Palace, H.R.H. The Duke of York, *in an address of welcome*, referred to the recent establishment of the British Red Cross Clinic for Rheumatism, in London, as an instance of Red Cross activity with which, he hoped, visitors would make themselves acquainted. Among the imperial activities were child welfare work in India, the promotion of health education in South Africa, nursing service for women and children in Canada, and the combating of tuberculosis in Australia.

Lord Passfield, Secretary of State for the Dominions and Colonies, spoke also of imperial developments, especially the organization of nursing in New Zealand under Red Cross auspices. He gave his unreserved testimony to the value of voluntary agencies as an auxiliary to Government service, and said that in this country those charged with the public health were learning more and more to depend on voluntary effort. It was true that there were some spheres which must always remain closed to voluntary organization—he instanced the care of the insane, which must be under the control of the State—but in many other respects voluntary organization was indispensable in every civilized community, not least because it had the advantage of initiative and experiment.

Short addresses were then delivered, describing what was done in their respective countries, by representatives of the Red Cross Societies of Australia, Canada, New Zealand, South Africa, and India; and M. Max Huber, president of the International Committee of the Red Cross, added a few words, affirming that the new activities in the field of peace were in the line of Red Cross evolution.

At the second session, also held at St. James's Palace, *under the chairmanship of Sir Arthur Stanley*, brief welcoming addresses were delivered by Mr. Thomas Shaw, Secretary of State for War, and Mr. Arthur Greenwood, Minister of Health. Dame Maud McCarthy, matron-in-chief of the British Expeditionary Force, paid a high tribute to the V.A.D. in the great war, saying that their immense work would be inscribed with everlasting gratitude in the history of the nursing profession throughout the Empire.

Major-General Sir Percival Wilkinson, of the Order of St. John, described the close co-operation between that organization and the British Red Cross Society, whereby overlapping was avoided. Since the society established its clinic for rheumatism, the Order, which also had in London a light and electricity clinic, treating the same class of patient as the clinic at Regent's Park, had consulted with the society, and borderline cases were, by agreement, handed over to one institution or the other, as seemed most suitable. In the course of the discussion Brigadier-General W. F. S. Edwards, representing the Devonshire branch of the society, urged complete amalgamation of the two bodies, instancing how the existence of the two led to some overlapping. The suggestion, however, was not to the taste of the conference. Dr. Wheeler Hart said that St. John, the oldest Order of chivalry, numbered among its members very many who were profoundly jealous of its reputation and authority, and the Red Cross, though much younger, valued highly the position which it had attained. These organizations could not be run apart from sentiment, and co-operation, not amalgamation, should be the aim.

The conference divided itself into four committees to consider, respectively, the training and organization of voluntary aid detachments, the mobilization of the Red Cross for the improvement of health and the provision of relief, various aspects of the Junior Red Cross, and methods of increasing popular membership and raising funds. The reports were to be presented at a final plenary meeting at St. James's Palace on Friday morning, of which we hope to give some account next week.

PREVENTIVE MEDICINE IN THE CURRICULUM.

REPORT BY THE SOCIETY OF MEDICAL OFFICERS OF HEALTH.

A SPECIAL committee appointed twelve months ago by the council of the Society of Medical Officers of Health to consider the teaching of preventive medicine in the medical schools, and the requirements of the examining bodies in this respect, has issued its report. Professor W. W. Jameson, director of the Public Health Division of the London School of Hygiene and Tropical Medicine, was chairman of the committee, and its ten members, with the exception of Dr. H. B. Brackenbury, were professors or lecturers in public health at the universities and medical schools. The report has been unanimously approved at a recent meeting of teachers of preventive medicine.

The first task of the committee was to collect information and expressions of opinion from teachers in this country, and also to ascertain the character of the syllabuses of Continental and American schools. It was particularly desired to find out to what extent the medical schools of this country have adapted their courses to the requirements laid down seven years ago, when the General Medical Council passed resolutions expressing the view that throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of medicine. The present report states:

"It can hardly be said, however, that a concerted endeavour has been made by the staff of any school to seize the opportunity afforded them of breaking with tradition and of introducing into their general teaching a real emphasis on the importance of prevention. Indeed, both the resolutions of the General Medical Council and the writings of Sir George Newman [a reference to his *Recent Advances in Medical Education in England*] have apparently exercised a much greater influence on medical opinion in America and in various Continental countries than in our own."

After nearly twenty years of national health insurance—a system based on the prevention of sickness as much as on its cure—it is only within the last few years, the report adds, that any attention has been paid to the problem of conserving the health of insured persons, and this owing mainly to the efforts of those engaged on administrative duties in connexion with the scheme. That there exists a public demand for advice on the maintenance of health and the avoidance of disease is obvious from the growth of societies engaged in health propaganda, and the attention given to such matters in the press.

The responsibility for such a state of affairs must be attributed in the main, according to the committee, to the present method of medical education:

"The medical student lives in the atmosphere of the dissecting room, the laboratory, the operating theatre, and the hospital ward. His whole attention is directed to what is abnormal, and he is taught to think almost entirely in terms of individual sick persons, and never at all to regard himself as a member of a profession with great communal responsibilities. While there must always be a comparatively small number of specialized medical practitioners devoting themselves wholly to preventive work and to the administration of the public health services, it is to the main body of general practitioners that the people must look for personal guidance in prevention and in the detection of the beginnings of disease."

Although the two branches of the profession have tended in the past to proceed along rather separate lines, the provisions of the Local Government Act will result in many more practitioners than in the past being brought into intimate contact with various branches of the public health service.

The Position in Great Britain and Elsewhere.

Information gathered from the universities and medical schools in this country shows considerable variation of practice. In London the course of preventive medicine consists, as a rule, of ten to twelve lectures; in the provinces, of

twenty lectures; and in Scottish schools, of forty to sixty. There has been great improvement in teaching during the last twenty years, and most lecturers bear in mind the fact that the majority of their students will enter general practice. It is stated that all London teachers of preventive medicine are dissatisfied with the attention paid to the subject in the examinations, provincial teachers express no such dissatisfaction. Attention is drawn to the English Conjoint Board examinations, where a question on the subject may or may not be included in one of the papers headed "Principles and practice of medicine." Out of eight English Conjoint Board papers containing forty questions in all, set during 1928, only two questions had any relation to preventive medicine.

The practice in other countries is briefly summarized in the report. In Germany all candidates for the State examination in medicine must have attended a course of lectures on hygiene given by a specially selected lecturer. In Holland the lectures on hygiene are given during the last year of study—usually four times a week. In Denmark a course of lectures and visits is given during one term. Of American universities one of the most interesting is the Vanderbilt where the scheme includes a course of forty-four lectures to fourth-year students, and sixty-six hours of laboratory work and field demonstrations. At Toronto a course of forty lectures is given to fifth (penultimate) year students.

The committee concludes that the special lecturer on public health and preventive medicine should be in a position to leave to others the discussion of the scientific basis upon which the system of public health is built, and so confine his teaching to the consideration of the principles of prevention as applied to the general well-being. Much help might be given by teaching more applied physiology during the early months of the course, and opportunities for emphasizing prevention offer themselves in every one of the subjects in the curriculum, especially bacteriology, obstetrics, gynaecology and paediatrics.

Special Syllabus and Examination Tests.

A special syllabus, which does not pretend to be exhaustive, is given in the report. The main headings are: historical summary; sources of statistical information; maternity and child welfare, care of the school child; the adolescent and the child; prevention and control of communicable disease; special problems of certain communicable diseases; the influence of environment; food and the public health; and the health of workers in various industries.

Visits should be paid to places of public health interest, such as maternity centres, and it is suggested that students might pay such visits during their vacations. The committee hesitates to specify the number of hours which should be assigned to the special lecturer. If there is adequate co-operation with other members of the teaching staff a minimum of twenty-four hours should be provided in the special courses, but in the absence of such co-operation more hours must be allotted to the special subject. The course in public health should not be taken earlier than the penultimate year. It is added that adequate training can never be given by any *ad hoc* course of instruction, but only by active co-operation of all teachers of the school.

With regard to examinations, the examination tests are held to be of far less consequence than the establishment of an adequate course of instruction, but often the only means of securing the latter is the rigid enforcement of the former. Every medical student should be required, in the committee's opinion, to pass a separate examination in public health and preventive medicine, consisting of a written and oral test. The paper, which should be part of the final examination, should contain five questions, with a definite medical bias. In the other professional examinations also candidates should be expected to show some knowledge of the preventive aspects of the subjects taken.

THE COMMITTEE'S RECOMMENDATIONS.

The full text of the report is published in the May issue of *Public Health*. The committee's recommendations are as follows:

1. In every medical school a scheme should be prepared showing how each department can co-operate in teaching preventive medicine, and the authorities should put an approved scheme into operation at the earliest possible moment.

2. If an adequate scheme is adopted, a minimum of twenty-four lectures in the special course on public health and preventive medicine may be delivered.

3. The course would not be held earlier than the penultimate year.

4. The syllabus sketched previously to be taken as a model outline.

5. Medical officers of health should be invited to co-operate in the training by affording facilities to students for becoming acquainted with branches of public health work undertaken by local authorities.

6. No student to have a registrable qualification who has not passed a separate examination in public health and preventive medicine; such examination should include a written test of not less than five questions, and an oral test, and should form part, if possible, of the final qualifying examination.

7. Questions dealing with the appropriate aspect of preventive medicine should be included in the other subjects of the various professional examinations.

It is intended that the report shall be submitted to the General Medical Council for its information and consideration.

Ireland.

Irish Free State Medical Registration Council.

A MEETING of the Medical Registration Council for the Irish Free State was held in Dublin on May 6th, with the president, Dr. Dennis J. Coffey, in the chair. After arrangements had been made for the future accommodation of the Council and the office of registrar, the Council appointed the president to be returning officer for the election to fill a casual vacancy caused by the lamented death of Dr. Maurice Hayes, F.R.C.S.I., whose daughter, Miss Eileen Hayes, has been appointed registrar of the Council. The time for election expired at 1 p.m. on May 16th. Only one nomination paper having been received during the prescribed period, Mr. William Doolin, M.B., B.Ch. N.U.I., of Dublin, was declared by the returning officer to be duly elected. The new office of the Medical Registration Council is 35, Upper Fitzwilliam Street, Dublin.

Medical Benefits for Northern Ireland.

The text of the National Health Insurance (Medical Benefits) Bill was presented to the Northern (Ireland) Parliament on May 13th. It will be remembered that the Right Hon. J. M. Andrews, Minister of Labour, addressed a communication in December last to the Armagh Board of Guardians stating that the Imperial Government had made strong representations to the Government in Northern Ireland to introduce legislation making provision for the inclusion of medical benefits under the National Health Insurance Acts so that the Imperial Government may be enabled to ratify certain conventions drawn up by the International Labour Offices at Geneva in 1927. These conventions required the subscribing countries to provide medical benefits for workers, including those engaged in agricultural employment, on an insurance basis. The bill proposes to make the Ministry of Labour responsible for administration of medical benefit with the assistance of a Medical Benefit Council which will act in an advisory capacity. This council will consist of not fewer than twenty members or more than forty. It will be representative of insured persons, employers, doctors, and dentists: in addition, there will be certain representatives appointed by the Minister of Labour. There will be also local committees representative of insured persons, doctors, and chemists. It is provided in the bill to raise the rate of contribution in Northern Ireland to that payable in Great Britain in order to meet the cost of medical benefit. A considerable number of insured persons in Northern Ireland receive medical treatment under the dispensary system. With regard to such cases negotiations have been taking place for some time between the Ministers of Labour and Finance and the dispensary doctors. An agreement was reached before the introduction of the bill, with the result that a reduced capitation of 7s. 6d. will be paid to dispensary doctors for the treatment of insured persons, and it is also

part of the agreement that there will be no reduction in the existing salaries of dispensary doctors, nor any interference with their pension rights. The capitation rate for doctors on the panel, other than dispensary doctors, will be on the same basis as in Great Britain.

Coombe Lying-in Hospital.

The annual meeting of the Coombe Hospital Linen Guild, Dublin, was held at the hospital recently under the presidency of Mrs. McNeill, wife of the Governor-General of the Free State. The annual report for 1929 showed a decrease in the number of articles provided. During the year, which was a particularly busy one for the hospital, 1,500 births took place in the wards, and 1,200 in the Coombe district attended by the hospital staff. More workers and increased funds are required to carry on the work of helping to provide clothing in the district, which is one of the poorest in Dublin. Sir William Taylour, F.R.C.S.I., in proposing the adoption of the report, said that he knew of no other organization that gave more practical support to their hospitals than the linen guild. The hospital was doing work of such national importance that it should be supported by the public. At a conservative estimate the Dublin hospitals were £130,000 in debt. It would take almost as much more to bring them up to modern standards. A quarter of a million pounds was required. They could not go to the Government for the money, as Government support would increase taxation. Every source of income had been investigated, but the fact was that people had not the money to give. The only means left to the hospitals to enable them to carry on their work was the sweepstake. Those who suggested sweepstakes received a great deal of abuse in the papers and elsewhere. It was said that sweepstakes were immoral, but he could not find any Commandment that could possibly be made to refer to them, except, perhaps, "Thou shalt not covet thy neighbour's goods." The money obtained by sweepstakes, however, did not belong to any individual, and the person who bought a ticket certainly did not by that action covet anyone's goods. He could not see how the immorality or the sin arose; but he supposed it was an ethical matter which he must leave to churchmen to decide. Only by means of sweepstakes could the hospitals of Dublin be cleared of debt and made fit for the successful practice of modern surgery and medicine. Mrs. Kevin O'Higgins seconded the motion, which was passed.

Peamount Sanatorium.

Dr. Alice Barry, medical superintendent of Peamount Sanatorium, in her report for 1929, states that the average daily attendance of patients from about fifteen counties was 243. From a medical point of view the establishment of a colony at Peamount would obviate the need for "readmissions." There was a children's pavilion for fifty or sixty children, who were making their own hosiery, underclothing, etc. Mr. P. Bermingham, surgeon dentist, reports that 459 patients attended the surgery during the year. The carpentry work done by twenty-five men under the Papworth scheme, started in January last, was valued at £545. Orders were needed for wooden portable buildings of all types. Sir Conway Dwyer, F.R.C.S., chairman of the general committee of management, in moving the adoption of the report, said that the patients were showing much interest in the new industry, which should not be allowed to fail for lack of support. During the year 256 visits were paid to patients in their homes.

Prevention of Psittacosis.

The circular letter, addressed to the sanitary authorities in the Irish Free State from the Department of Local Government and Public Health, states that it has come under notice that during the last part of 1929 and since the beginning of the present year numerous cases of a serious disease, called psittacosis, have occurred in England and certain Continental countries, which are in close communication or have constant trade relations with Saorstat Eireann. The disease has been found to be associated with sickness in parrots and with close contact with these birds. The cases of human illness so far reported have apparently been infected by newly imported parrots, and there has not been any ground for apprehending danger from cage-birds of that species which have already been kept in households for more than a year. It is, however, to be noted that the conditions favouring the origination of the sickness among parrots are overcrowding, fouling of food, water, cages, etc., and strict attention should be paid to maintaining cleanliness of the birds and their surroundings. In view of the serious nature of psittacosis, and the relatively high rate of mortality resulting from outbreaks thereof, the Minister has deemed it necessary, for the purpose of obviating as far as possible the danger of its introduction into Saorstat Eireann, to make regulations entitled the Importation of Parrots (Temporary) Regulations, 1930, prohibiting the importation of any bird of the parrot species. These regulations come into force forthwith.

Scotland.

Health of Scotland.

THE following notes, extracted from the first annual report of the Department of Health for Scotland,[1] are in continuation of the paragraphs published in this column on May 10th (p. 879) and May 17th (p. 922).

Maternity and Child Welfare.

There are 87 pre-natal centres in Scotland specially equipped and staffed for the examination and advice of expectant mothers, so that difficulties or complications at confinement may be detected. The number of expectant mothers who attended the centres in 1928 was 14,941 and their total attendances were 46,935. Of this number 2,611 were referred to pre-natal wards for treatment. Health visitors made 25,275 supervisory visits to 11,110 expectant mothers. Almost one-half of the births in Glasgow were attended by midwives, of whom there were approximately 300 in practice; in Dundee midwives attended at over 40 per cent. of the total births. The number of practising midwives in Scotland early in 1929 was approximately 4,750, including those in institutions. At the end of 1929 there were 110 maternity homes registered by local supervising authorities, and a number of convalescent homes available to mothers for rest and recuperation. A Glasgow scheme for "home helps" has been in operation since 1924, and a steady increase is reported in the demand for their services. During the year 1929 there were 92,876 births, representing a birth rate of 19.02 per 1,000, as compared with 19.79 for the year 1928. The number of children under 1 year of age who died in Scotland during 1929 was 8,058, representing an infant mortality rate of 86.8 per 1,000 births, compared with 85.7 for the previous year. It is pointed out, however, that prior to 1915 the rate was constantly over 100, but that since that year it has exceeded 100 on three occasions only. The total number of children in Scotland between the ages of 1 and 5 years during 1929 was approximately 352,000, and the death rate was 11.8 per 1,000 in this age group. Health visitors made 341,145 visits; the number of children in this group who attended centres during 1928 was 14,711. At most, approximately one-third of the children in Scotland of this age group have come under health supervision provided by maternity and child welfare schemes, although local authorities are endeavouring to extend the work of their health visitors for the benefit of this group.

School Health Administration.

It is recalled that medical inspection of school children has been general in Scotland for twenty-one years—since the powers conferred by the Education (Scotland) Act 1908. Adequate schemes for treatment of children had come into operation in the burghs by 1914, but medical treatment in the counties was mainly a post-war provision. Under the education authorities established by the Act of 1918 the school medical service was greatly facilitated. The development of medical examinations in schools is indicated by the fact that the number of children inspected increased from 258,130 in 1919 to 471,979 in 1929, while the number of children treated in the two years was

[1] Cmd. 3529. Edinburgh: H.M. Stationery Office. 3s. 6d. net.

respectively 68,526 and 236,025. The medical staff employed in this work in Scotland in 1929 consisted of 37 chief school medical officers, of whom 21 were also county medical officers of health, 64 assistant medical officers, of whom 13 were part-time officials, 47 part-time local practitioners, 82 dentists, of whom 37 were part-time officers, 64 specialists in various departments, and 684 nurses, of whom 481 were district nurses.

Infectious Diseases.

The notification statistics for the sixteen principal towns of Scotland show a decrease in the number of cases of infectious disease amounting to nearly 10,000 compared with the figure for the preceding year. The principal cause was the lower prevalence of measles and whooping-cough. The death rate over the whole country from the "principal epidemic diseases" fell from 0.71 in 1928 to 0.48 in 1929. The death rate from tuberculosis in Scotland per 100,000 of the population was 84 in 1929, compared with 97 in the previous year. Sanatoriums approved for the treatment of tuberculosis numbered 119, and provided altogether 5,114 beds compared with 4,634 in 1928. If the average number of beds used for this purpose in other hospitals is added, there is in Scotland approximately one bed for tuberculosis treatment for every 900 of the population. With regard to venereal disease 51 treatment centres have been established; the number of patients dealt with during the year was 29,880, including 11,934 new patients. The total number of attendances by all patients was 460,896, and the total expenditure on this service was £82,500, of which 75 per cent. was repaid from the State grant.

Highlands and Islands Medical Services.

The passing of the Highlands and Islands (Medical Service) Additional Grant Act, 1929, has opened a new chapter in the medical history of the Highlands and Islands. The new Act provides that in addition to the annual grant of £42,000, sums may be voted annually by Parliament. Advantage has been taken of opportunities to extend the services of district nurses, and to encourage local associations to appoint nurses with full general and surgical training. The advent of the light car has made a full and efficient nursing service possible in many places; in some districts a small car enables two nurses to do in comfort the work that had previously required three. Specialist surgical services are now firmly established in Lerwick, Kirkwall, and Stornoway.

Edinburgh Royal Infirmary Appeal.

The managers of the Royal Infirmary of Edinburgh are launching an appeal to the public for £500,000 for the extension of the institution. For this purpose a preliminary meeting was held in the Edinburgh City Chambers on May 16th, at which Lord Provost Whitson presided. The chairman explained that the bicentenary of the Royal Infirmary was being made an occasion for the public to show its appreciation of the services which it had rendered in the past two hundred years. The execution of the necessary arrangements was remitted to an executive committee consisting of about forty members. Sheriff Brown described the appeal as the greatest and widest that had ever been made for the common weal in Scotland, and said that the merits of the cause were so great that it was bound to succeed if the machinery for gathering the money worked efficiently. Year by year the Royal Infirmary had dealt with an increasing number of cases; the accommodation available could not meet the demand for treatment, so that the extension of the institution was an obvious necessity. The contemplated extension includes a new hostel for nurses and three additional ward blocks, one of them being intended for midwifery in place of the present Simpson Memorial Hospital.

Autumn Post-Graduate Course in Glasgow.

Under the auspices of the Glasgow Post-Graduate Medical Association a course of instruction will be given in that city during the last two weeks in August and the first fortnight in September. The course includes most of the subjects of interest to the general practitioner. Mornings will be devoted to general medicine, surgical diagnosis, and minor surgery, in the Western Infirmary and Royal Infirmary. In the afternoons special subjects will be studied in special hospitals or in special departments of the general hospitals. During the summer months as well as at other times of the year a limited number of clinical assistantships are available in institutions in the city taking part in post-graduate medical teaching. These assistantships are intended to provide opportunities for specialized study and investigation. Graduates may be attached to wards or to out-patient departments, where they will be under the direct supervision of the physician or surgeon in charge. As in the previous year, those who desire to take advantage of these appointments must be prepared to devote to the work either the whole or part of the day, according to the terms of the particular assistantship. Enrolment is recommended for a period of three months, although shorter periods are considered. The inclusive fee for the general medical and surgical course is £10 10s., or £6 6s. for the first or second fortnight. Intending applicants may obtain further information from Dr. James Carslaw, secretary of the Glasgow Post-Graduate Medical Association, the University, Glasgow.

Selkirkshire Education Authority.

The final meeting of the County of Selkirk Education Authority was recently held in Galashiels under the chairmanship of Dr. E. M. Tyrrell. A minute of meeting of the Medical Services Joint Committee stated that lectures had been given by Dr. Calder (Stow) on milk in relation to health and disease; by Dr. Robertson, medical officer of health for Edinburgh, on "Our future health"; and by Colonel Lelean, professor of public health at Edinburgh University, on sex education. The minute also recorded that informal meetings of the staffs of several of the larger schools had been convened for the discussion of health matters by the school medical officer and by one of the education authority's dentists. A letter was submitted from the county clerk asking the authority to nominate a member to serve on the new education committee of the county council. Mr. J. Easton, vice-chairman of the educational authority, in proposing Dr. Tyrrell, said that he thought it would be a disaster to the educational interests of Selkirkshire if the services of Dr. Tyrrell, who had such a wide experience of educational affairs, could not be retained. Dr. Tyrrell regretted that he could not accept the offer. Had it been possible he would have been very glad to continue to give his services, but he was at present a paid officer of the council holding two part-time appointments. For that reason he was not eligible to be either an elected member or even a co-opted member of the education committee. Mr. Easton was then unanimously chosen as the authority's nominee. In thanking the members for their support during his term of office Dr. Tyrrell remarked that he had been associated with education for twenty-seven years, first as a member of the Galashiels school board, and later as chairman of the authority; he would have liked to complete thirty years. As one who had been intimately acquainted with the work of the authority during the eleven years of its existence he could look back with pride and satisfaction at the large amount of good work which had been done to promote education in the county of Selkirk. It was in a state of very high efficiency; schools were in excellent condition, and the teaching staff was at least equal to any in Scotland. He could not but regret the abolition of the administrative machine. Referring to Dr. Tyrrell's services Provost Ballantyne said that no chairman could have been more highly esteemed. Similar tributes were paid by other members of the authority.

Growth of Officialdom.

An address was delivered at a meeting of the Edinburgh Business Men's Club on May 13th by Dr. John Guy, deputy medical officer of health for Edinburgh, under the chairmanship of Sir Joseph Dobbie. Dr. Guy said that the ordinary citizen might well be amazed at the enormous number of officials by whom he was now surrounded and safeguarded, and who tended to increase rather than diminish. When he entered the service of the public health department, sixteen years ago, the medical officer of health

was the only officer in the department, but during the comparatively short time that had elapsed, three sub-chiefs, each with his own appropriate staff, had been added, and there were now eleven full-time medical officers and approximately thirty health visitors, apart from hospital staffs. In 1912 the city of Edinburgh spent nothing on tuberculosis, child welfare, or venereal diseases; to-day the public health department spent approximately £29,000 on tuberculosis, £19,000 on child welfare, and £23,000 on venereal diseases. The total public health expenditure in Edinburgh had risen from £35,000 in 1912 to £175,000 in 1929. He thought that there was an adequate return for all this expenditure, but a tendency was occasionally observable on the part of some officials to forget that they held their positions in a very complete sense as servants of the public, and to cultivate not only efficiency but an aloofness and superiority of bearing which could only be surpassed by the Syrian camel. Officials in all spheres of life, whether civic or national, should, by virtue of their position, look upon themselves as the helpers, assistants, and servants of the general public.

Central Midwives Board.

The examinations of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, have just been concluded, with the following results. Out of 152 candidates who presented themselves for the examination 141 passed. Of the successful candidates 67 were trained at the Royal Maternity Hospital, Glasgow; 23 at the Royal Maternity Hospital, Edinburgh; 5 at the Maternity Hospital, Aberdeen; 6 at the Royal Infirmary, Dundee; 13 at the Elsie Inglis Memorial Hospital, Edinburgh; 8 at Stobhill General Hospital; 4 at Barshaw Hospital, Paisley; 6 at the County Maternity Hospital, Bellshill; and the remainder at various recognized institutions.

England and Wales.

The Order of St. John and the British Red Cross Society.

THE Joint Council of the Order of St. John and the British Red Cross Society was established in 1920; the removal of its offices to 12, Grosvenor Crescent, S.W.1, is now announced. The question whether the alliance between the Order and the Society, which had been so effective during the war, should be continued was much discussed at the time of the armistice, but the experience of the past ten years has shown that the existence of a link by means of which the united forces of the Order and the Society can be brought into action has a distinct value. Thus, for example, during the industrial disturbances of 1921, 1924, and 1926, the authorities were enabled, through the Joint Council, to secure the complete co-operation of the Order and the Society in regard to first aid and transport at very short notice. Continuation of the work of the old Joint War Committee in caring for those disabled by war service has been the first consideration of the Joint Council, which has during the past ten years disbursed over one and three-quarter million pounds in promoting the comfort of ex-service men and their families. This gigantic task has been rendered possible by the co-operation of members of the Order and the Society, not only in London, but in all parts of the country. Thanks to the great number of voluntary workers of the two bodies the many individual cases have received immediate investigation and prompt assistance, a voluntary association with its power to act quickly being in this way a most valuable adjunct to an official organization. An outstanding achievement of the Joint Council in regard to the health of the civil population has been the Hospital Department, which was organized by the late Sir Napier Burnett; after his death it was developed further by Dr. Kay Menzies, and later by Mr. R. H. P. Orde. A complete survey has been made of the work of the provincial hospitals, and a bureau of hospital information has been set up, associating the council with the British Hospitals Association and the Incorporated Association of Hospital Officers. The bureau has proved of the greatest value to those concerned with the administration of hospitals, both at home and abroad. Steps to improve the system of invalid transport in the country generally were taken by the Order and the Society immediately after the war, and under the Joint Council a national ambulance service has been established with a number of well-equipped motor ambulance stations in every county. This service has been of very great advantage to the sick and to the medical profession; it mobilizes more effectively the latest discoveries of science as regards the diagnosis and cure of disease. The road service, promoted by the Joint Council as an auxiliary to the ambulance service, is designed, by means of first-aid cabinets and dressing stations, and by week-end patrols of the roads by members of the Order and the Society, who are qualified in first-aid practices, to minimize as far as possible the consequences of the increasing number of traffic accidents. The existence of a Joint Council facilitates the co-operation of members of the two societies in such philanthropic work as the council itself undertakes, and tends to promote closer relationship between the Order and the Society in the independent undertakings for which each organization is separately responsible. An instance of this is afforded by the two great curative institutions, the Clinic for Rheumatism in Peto Place, founded by the British Red Cross Society, and the London Light and Electric Clinic in Ranelagh Place, controlled by the Order of St. John. A friendly understanding has been reached which provides for the interchange of patients, or such other mutual help as may best promote the relief of suffering and cure of disease, which is the ideal of both societies. The Joint Council should thus be able to continue its work in its new home with the confidence that it fulfils a useful purpose in making it possible to place the combined resources of the Order of St. John and the British Red Cross Society at the service of the nation, without detriment to the continuance of the separate activities which each society carries on from its own headquarters for the benefit of the health of the people.

Mr. Hayward Pinch.

The retirement of Mr. A. E. Hayward Pinch, M.B., F.R.C.S., after twenty-one years' service as superintendent and director of the London Radium Institute, is announced to take place next month. The reorganization of the work of the institute consequent on its affiliation with the Mount Vernon Hospital and the setting up of the new Post-Graduate School of Radio-Therapy is in progress, and Mr. Pinch's state of health prevents him from undertaking new and more onerous duties. The committee desire to put on record their deep appreciation of the devoted service Mr. Pinch has given to the Radium Institute during his long tenure of office, and have elected him a member of the honorary consulting staff.

Manchester Medical Society.

At the annual meeting of the Manchester Medical Society held on May 7th in the University, with the president, Mr. J. Howson Ray, in the chair, Mr. A. E. Webb-Johnson, surgeon to the Middlesex Hospital, delivered an address entitled "Memories, Experiences, Doubts, and Fears." Mr. Webb-Johnson first expressed appreciation of the teaching he had received at his Alma Mater, the Manchester Medical School, and paid tribute to some of his old teachers, referring particularly to Dr. Judson Bury's class in neurology, the work of Dr. Archibald Donald, and to Mr. Alexander Wilson. He expressed special gratitude to the surgeons with whom he had worked, particularly to Mr. F. A. Southam and Joseph Collier, for whom he had acted as dresser, and Sir William Thorburn, under whom he held an appointment as house-surgeon and to whom he was private assistant some years. In lighter mood Mr. Webb-Johnson then related some of his experiences, particularly those which had exciting, interesting, romantic, or social complications. The more serious part of the address dealt with a variety of subjects which had occupied the lecturer's attention a good deal in recent years, and which had at times raised his doubts and fears. He dealt particularly with the need of financial support for medical education and research, and the opportunities which medical men so often had of bringing rich men to see the importance of this cause. He emphasized how essential it was for each

medical school to have sufficient endowments to develop with freedom, and along the lines best suited to the conditions prevailing in the particular centre. He felt strongly that there were great disadvantages in professors of clinical subjects being precluded absolutely from private practice. He dealt also with the question whether more or less experimental operations, citing particularly those on the stomach and duodenum, should be performed by hundreds and even thousands before their true value was determined. He criticized the sharp division between medicine and surgery—physicians taking so little interest in the patient after being passed to the surgeon, and the surgeons too often not being sufficiently acquainted with the physiology and pathology of the conditions for which they were operating. The true specialist, doing everything for the region for which he studied, would acquire a better perspective, and arrive sooner at the best line of treatment. The lecturer also expressed the opinion that operations accompanied by a high mortality should not be recommended without first giving the patient some indication of the risk to be faced, the chances of complete success, and the prospects if alternative lines of treatment were followed. He advanced very strong criticisms of the records departments and the "follow-up" arrangements of hospitals; the "following up" of cases should be a recognized duty of hospital authorities. In his opinion the only way to make records of cancer cases complete and of real value was to make them national in character and institute a system of compulsory notification with special certificates in case of death. Mr. Webb-Johnson's address finished with a plea for research into the beginnings of disease and for investigation of those subtle changes which were the precursors of serious disease and about which little or nothing was known. He outlined a scheme whereby observations could be made on a larger number of apparently healthy persons over a long period of time in order to detect the transitional stages from the normal to the pathological, and in this way to ascertain the changes which indicated the real beginnings of disease.

Prevention of Noise.

An example of how local authorities may obtain powers to deal with noise nuisances is afforded in a bill recently submitted for the consideration of a local legislation committee of the House of Commons by Stockton-on-Tees Corporation. One of the clauses of this bill provides that the corporation should be able to take action in the case of noise that is excessive, unreasonable, unnecessary, or injurious to health; but if the noise is made in the course of business it should be a good defence that as much as possible has been done to mitigate it. Mr. A. Moon, K.C., appearing before the House of Commons Committee on April 8th on behalf of the corporation, said that it was possible at present to take High Court proceedings against anybody making a noise nuisance, but owing to the expense involved this procedure was not open to the ordinary individual. If the clause was granted this state of affairs would be remedied. Dr. G. C. M. M'Gonigle, medical officer of health for Stockton, said that it was difficult to lay down an exact definition of a noise nuisance, but each case would have to be considered on its own merits. He cited as examples complaints that had been made about the noisy unloading of milk churns at a dairy, and about the installation of electrically operated machines which made loud and strident music in small shops from early morning to late at night. At present there was no power under which the corporation could take action if unreasonable and unnecessary noise was made in connexion with any trade, business, or occupation. The first step under the clause before the committee would be to issue an intimation of the breach, a course of action which was generally effective in other nuisance cases; the second step was a statutory notice, and the third a summons before a magistrate. In reply to a question put by Colonel Heneage, a member of the committee, Dr. M'Gonigle said that at present the unloading of milk churns was accompanied by so much noise because they were dumped from lorries on to stone floors; if rubber floors were put in not only would the noise be prevented, but incidentally the milk churns would be protected against damage. Sir Ernest Holderness, for the Home Office, asked how the corporation was going to stop the nuisance caused by electrical machines. Dr. M'Gonigle replied that an order for abatement of the nuisance would be obtained from a magistrate. He had in mind as an example a small café and ice-cream shop which had installed an electrically operated gramophone that made a noise like a fog-horn. The people in the neighbourhood were seriously disturbed, but though theoretically there was a remedy at law the cost was prohibitive. After some consultation the committee decided by a majority vote to approve the clause, on the understanding that the corporation would not take action in petty matters, but would try to arrive at agreements with parties rather than carry matters into court.

Collection and Disposal of Refuse.

A lecture on the collection and disposal of refuse was given, as one of the Chadwick public lecture series, on May 15th, at the Royal Sanitary Institute, by Mr. Edward Willis, M.Inst.C.E., chief engineer to the urban district council of Brentford and Chiswick. Sir George Humphreys, K.B.E., presided. Mr. Willis, whose lecture was illustrated with numerous slides tracing the gradual improvement effected during the last half-century, gave some historical account of the collection of house refuse, which is really a very modern sanitary measure. Such collection was entirely ignored until the nineteenth century. Even far into the century, and, indeed, right down to the passing of the Public Health Act, 1875, which consolidated certain previous legislation, the disposal of other types of town refuse received more or less scant consideration, except in certain cities where private Acts of Parliament provided for sanitation. Mr. Willis then went on to describe the different types of refuse which needed to be collected if nuisance and ill health were to be avoided. While motor transport for this purpose was more efficient under certain conditions, the horse was more effective, as well as more economical, for the actual house-to-house collection where the distance to the shoot was not great. Various means of disposal of refuse were then considered. The first of these was indiscriminate dumping, which was wholly to be condemned as a nuisance and should be absolutely stopped under all circumstances. Dumping out at sea also was considered most undesirable. Then came the use of destructors and pulverizers, and, finally, controlled shoots. With regard to this last method, which had been brought very much into prominence by the city of Bradford, and was strongly supported in many instances by the Ministry of Health, while it had its advantages, the lecturer emphasized the important fact that it was unsuitable for and should never be applied on waterlogged ground, because the refuse was liable to pollute the ground water. It was also unsuitable where there existed certain water-bearing strata, but in many other cases it was an exceptionally useful method of treatment. The destructor served an excellent purpose, but it was often desirable to screen the refuse before actual disposal, since the calorific value of the dust was probably only 2,500 British thermal units, whereas the screened refuse might have a value of over 8,000. Again, the actual dust screened out was valuable as salvage for brick burning. The salvage question was a larger one than most people imagined. Any useful income from the collection and disposal of refuse was, in fact, salvage; thus waste land, otherwise useless, when treated with refuse on the controlled principle was subsequently able to be used for sports grounds, and brought in a regular income to the local authority.

University of London Medical Graduates Society.

The annual meeting and dinner of the University of London Medical Graduates Society was held on May 13th at the Langham Hotel, with the president, Sir StClair Thomson, in the chair. The guests of the society were Dr. Edwin Deller, principal of the university, and Professor G. E. Gask, dean of the faculty of medicine. The toast of "The Guests" was proposed by Lady Barrett. Dr. E. Deller, in the course of his reply, expressed the hope that before long the university would have a home on the Bloomsbury site, which would help to draw graduates together. The society was anticipating that central house,

and was helping to draw together the graduates in what was the biggest faculty in the university. "The Society" was proposed by Professor G. E. Gask, who drew attention to the high standard which the university had always maintained in medicine; though perhaps more glamour centred round the ancient universities, it was the high standard of medicine at London that would perhaps in the end cause London to outshine them. Mr. W. McAdam Eccles, in replying, outlined the steady growth of the society since its inception in 1928, and pointed out that with over 4,000 medical graduates of the university, the scope for the society was very great. He drew attention to the enormous debt which the society owed to Sir StClair Thomson for his labour on its behalf. The meeting was then declared by the president to be resolved into a business meeting, and the election of officers for the ensuing year took place: Sir John Rose Bradford, president; Sir StClair Thomson, past-president; new vice-presidents: Lady Barrett, Sir Charlton Briscoe, and Sir Cuthbert Wallace; new members of council: Dr. Ivor Davies, Dr. E. D. Granger, Miss E. Catherine Lewis, Dr. Herbert Spencer, Mr. Herbert Tilley, and Dr. A. J. Wrigley. Mr. W. McAdam Eccles was re-elected honorary treasurer, and Dr. C. A. H. Franklin and Dr. Dorothy C. Hare re-elected honorary secretaries, and Mr. Victor Bonney as honorary secretary for overseas members. The balance sheet was presented and adopted. It was announced that the next meeting of the society would take place at Bournemouth at the Royal Bath Hotel on June 20th.

National Baby Week Council.

In spite of serious financial difficulties the National Baby Week Council records a further extension of its services in its report for 1929. Much of the work undertaken by the council has already been referred to in these columns, such as the assistance it gives in organizing health and baby weeks, baby days, baby competitions, and to the preparation and exhibition of propaganda material in connexion with maternity and child welfare. In all these activities the council has surpassed its achievements of the previous year. This development has been accompanied by a desire on the part of local committees to work in closer association with the council. In the last three months of the year 57 new local committees appointed 99 members to represent them. Progress has also been made in the overseas department, which has 25 correspondents in the Dominions and elsewhere. As a result of the expansion of the health movement, and continued co-operation with the Empire Health Committee, maternity and child welfare propaganda was included during the year in health week programmes throughout the Empire. The Imperial Challenge Shield for the best baby week campaign organized in 1928–29 outside the British Isles was won by the Kalutara Totamune Baby Week Committee (Ceylon). During 1929 the council directed particular attention to practical measures for combating maternal mortality and disability, and for lessening the dangers of infectious diseases among young children. Another question selected for special propaganda was the importance of teaching parentcraft and hygiene to school children. In its campaign for 1930 the council is urging the need for arousing interest in parentcraft among those classes of the community which are not reached by statutory and voluntary schemes of maternity and child welfare. It is also emphasizing the need for a national maternity scheme and for the better provision of nursery schools. For the first three days of baby week, which will be held from July 1st to 7th, a national conference on maternity and child welfare is being organized by the National Association for the Prevention of Infant Mortality. The subjects for discussion are: (*a*) the relationship between housing and child welfare; (*b*) infant mortality during the last twenty-five years; (*c*) the variations in young child mortality in different areas; (*d*) the relationship between orthopaedic and child welfare centres; (*e*) the care of the child of pre-school age in industrial and rural areas. Many propaganda films will be exhibited during the week. Application for admission to this display, which is by free ticket, should be made to the secretary, 117, Piccadilly, W.1.

Correspondence.

DIGITALIS IN PNEUMONIA.

SIR,—I was much interested to see in the proceedings of the Royal Society of Medicine (*British Medical Journal*, May 3rd, p. 824) the account of Professor W. E. Dixon's observations on the curative action of digitalis in toxaemia and their bearing on its use in acute pneumonia.

For many years I have treated all cases of acute lobar pneumonia or broncho-pneumonia, when the heart shows signs of failure or the pulse rate is quick (100 or over), with digitalis, and I am convinced of its value in helping the heart to resist the depressant action which the pneumonia toxin has on it. I always use the infusion or a watery extract in solid form, because 75 per cent. of the water-soluble principles are eliminated on the day of administration, so pharmacologists say, while those which are insoluble in water take several days to be excreted. I also endeavour to get the patient to take as much fluid as possible in various forms—milk, lemon tea, weak tea, etc., and especially ordinary water at the temperature of the room. I have had as much as ten pints of fluid thus taken in the day. Such administration of fluid helps to produce perspiration—and also diuresis, when associated with the infusion of digitalis—and so to wash out some of the toxins of the pathogenic organisms.

In adults I begin with a drachm of the infusion every four hours, increasing it if necessary to as much as half an ounce every four hours, or even every three hours, night and day. Time and again have I seen a marked change for the good in the heart's action within twenty-four hours of ordering the infusion, and with its continued use cases which seemed hopeless have recovered. The infusion never accumulates in the system or produces heart-block as any other preparation of digitalis may do if given over a few days. It can be discontinued the day after the temperature has come down to normal by crisis or lysis; if half an ounce has been given every four hours, this large dosage can be at once reduced to three times a day, and be discontinued the next day. I have never seen any harm result from use of the infusion; no nausea is produced, and there is no subsequent heart-block.

The best effects are obtained if the drug is used about the second or third day, and not left until later, when the heart has become materially weakened—often beyond help.—I am, etc.,

Manchester, May 12th. E. M. BROCKBANK.

MATERNAL MORTALITY.

SIR,—I have to thank Professor Louise McIlroy for her references to my recent book on maternal mortality in her most valuable article in the *Journal* of February 15th (p. 269). Nevertheless, at the risk of being thought captious, there are two corrections which I must make.

Professor McIlroy writes: "He" (the writer) "states that in the Rotunda Hospital, Dublin, during the five years preceding 1898, the death rate was 3.1 per 1,000. He states that, while asepsis was unknown, intervention during labour was limited." Apologies would be due to Sir William Smyly and his Mastership but for the fact that I did not write thus. On page 2 of my book, I wrote: "In the past" (that is, in the obstetrically prehistoric past) "intervention during labour was limited, and asepsis was unknown," and on page 5, I wrote the sentence dealing with the Rotunda Hospital; there was no connexion between the two passages. The first sentence in the first edition of my small midwifery book, and almost the only sentence which has persisted unchanged during subsequent editions, is as follows: "It is not an exaggeration to say that the most essential knowledge in midwifery is the knowledge of asepsis." This was written in 1897, and resulted from Sir William's teaching.

Then Professor McIlroy writes: "*Rectal Examination.*—Dr. Jellett lays stress upon the advantages of this." Actually I wrote as follows: "I have not had considerable experience of rectal examination during labour, and consequently I am perhaps inclined to under-estimate its value.

Also, I am doubtful of its effect on the asepsis of a nurse who has enough difficulties to contend with without the added risk of faecal contamination." I am by no means sure that this view is right, but, such as it is, it is the one I hold at the moment. If I have written elsewhere anything that conveys an opposite opinion, I am ready to apologize in advance.—I am, etc.,

HENRY JELLETT.

Christchurch, New Zealand, April 2nd.

TREATMENT OF MAMMARY CANCER BY RADIATION.

SIR,—Sir G. Lenthal Cheatle, in his valuable lecture published in the *Journal* of May 3rd (p. 807), well said that "the final treatment by radiation will emerge after experience gained by the use of external radiation alone, of interstitial radiation alone, and by the combined use of external radiation and interstitial radiation." But, so long as external radiation is confined, as it practically is now, to the treatment of inoperable primary and recurrent patients, we shall remain ignorant of its real possibilities in breast cancer. I have shown[1] that with x rays, or with radium externally in large quantities from a distance, this method leads to valuable results, and my experience (based on over a thousand cases of breast cancer) does not accord with that of Sir Lenthal Cheatle as to the radio-sensitiveness of the disease in general, for practically every patient has shown regression (partial or complete) of the local signs of disease when so treated.

It should be realized that "radio-sensitiveness" is not a simple, but a complicated factor. What, for example, shows a more prompt response than a leukaemic gland? Yet the almost invariable recurrence shows that *some* elements (whether mother cells, specialized cells, or cell components, we do not know yet) are highly radio-resistant. The time factor in "radio-sensitiveness," in short, must be greatly widened in a full conception of it, and surgeons who are accustomed to see many immediate or "dramatic" results from operative intervention, or from the intense interstitial radiation of some radium insertions, should allow a longer time than the "three weeks" mentioned by Sir Lenthal Cheatle for the full effect of external radiation treatment to be shown. The full effect may be complete regression or partial regression, with the establishment of a "residue," which must be closely followed for many years before its inactivity is considered probable (many residues should be locally excised); or, in rare instances, usually in very advanced and cachectic patients, the growth proceeds unchanged.

Sir Lenthal Cheatle mentions Paget's disease of the nipple. A recent typical case (sent to me by Mr. Sampson Handley) shows, four months after two high-voltage x-ray treatment series, an apparently complete return to the normal the breast has no palpable nodule, the skin is normal, and the axillary gland has disappeared.

Sir Lenthal Cheatle announces himself as a new follower of the method of interstitial radiation of breast carcinoma introduced by Mr. Geoffrey Keynes and by Neumann, Sluys, and Coryn. But this method has only one primary site so far in which it has *established* its value—namely, tongue cancer, a disease in which, as a rule, only local metastasis occurs. Its ultimate value is certainly not yet established in any type of cancer which often shows generalized metastasis. Those who know the effect produced experimentally by Tyzzer and L. C. Knox, with massage of carcinomata in mice in producing multiple metastases, will be inclined to consider with scepticism the end-value of any method which may involve the insertion of up to 40 radium needles throughout the substance of a highly metastatic growth, such as sarcoma or breast carcinoma. I have already seen a number of rapidly supervening spinal and pelvic metatases, time alone will show if the proportion of these is increased after radium insertion methods, with the unavoidable manipulatory "massage" this entails. External radiation methods avoid this risk, and may in consequence be superior in value; or pre-operative external radiation should be a safeguard. Sir Lenthal Cheatle makes no reference to pre- or post-operative radiation, an important aspect of the subject as I have shown, for recurrences are thus lessened in number.

Dr. Hernaman-Johnson, in his comments in the *Journal* (May 17th, p. 926), refers to the possibility of secondary radiations from introduced metallic substances being of value. I have lately shown[2] that this hope appears to be chimerical. In addition to the references there given, Holthusen has discussed the question in a fifty-page article in the *Ergebnisse der med. Strahlenforschung* (1925, Bd. 1, p. 385), and concluded that evidence as to its clinical value is completely lacking. Dr. Hernaman-Johnson refers to Moppett's experimental work, as Sir Lenthal Cheatle also does, with an encouraging note. But I am quite unable to see how Moppett's work with "monochromatic" beams from crystals can be applied to clinical conditions. Every beam we employ is polychromatic to some degree, usually to several tenths of an Ångström, even when heavily filtered. And to suppose that treating a patient with the very polychromatic unfiltered radiations from an x-ray tube "at 80,000 volts" reproduces in any way Moppett's conditions is wholly illusory, since his results appeared to show that closely adjacent wave-lengths had opposing effects on the growing chick-allantois. His work has at present no clinical bearing.—I am, etc.,

J. H. DOUGLAS WEBSTER.

London, W.1, May 17th.

UNDULANT FEVER IN GREAT BRITAIN.

SIR,—Might I be permitted briefly to support your suggestion (May 10th, p. 870) that a commission of inquiry should be instituted into the incidence of Brucella infection in animals and the value of the present prophylactic measures?

The problem which recently has been outlined by medical and veterinary clinicians and pathologists (vide "Discussion on Brucella infections in man and animals," *Proc. Roy. Soc. Med.* 1929–30, xxiii, 559) may be summarized as follows: (1) Brucella infection in man arises naturally in Great Britain; as yet its incidence cannot be gauged with accuracy; the source of infection appears to be principally, if not entirely, the diseased bovine or its products. (2) Brucella infection is the most widespread contagious disease of bovines in Great Britain: no indisputable evidence as to its incidence exists; the veterinary profession is acutely divided between hygienic prophylaxis and vaccination with the living organism; on account of this ignorance the wrangling continues, and so does the disease.

The time for regret and recrimination is past; the situation, at least on the veterinary side, is far too serious. The time for action has arrived, though not, I hope, by the Ministry of Agriculture alone. I contend, Sir, that Brucella infection of man and animals in Great Britain presents a single problem, indivisible between medical and veterinary, Ministry of Agriculture or Ministry of Health. But with your main contention I fully agree, and I hope a commission of instructed medical and veterinary representatives will be constituted to study and report upon this problem.—I am, etc.,

TOM HARE.

Department of Pathology, Royal Veterinary College, N.W., May 20th.

MIXED BRUCELLA INFECTION.

SIR,—A case of *abortus* fever under my care in Rapallo seems of sufficient interest to record, particularly as the illness would appear to have been contracted in London.

A. B., aged 64, left Dublin about the third week in October, and stayed at his London club for a fortnight. About November 5th he had a slight haemoptysis, which, like a previous attack two years before, was ascribed to high blood pressure. There were apparently no signs of a pulmonary lesion, and his systolic pressure usually ranges from 200 to 230 mm. Hg. For convenience in nursing his wife transferred him to a hotel, where for a few days he felt very well. The second week he felt ill, and had fever and diarrhoea, but as he had been subject to what he termed "nervous" diarrhoea for years he did not mention this symptom, and the attack was regarded as influenzal. By November 22nd he was considered well enough to travel out to Rapallo, but

[2] *British Medical Journal*, 1929, November 23rd, p. 983.

on arrival he went straight to bed, and remained there for about a week, with a return of fever and diarrhoea.

I first saw him on December 22nd, about three days after the commencement of a third attack, and found his temperature rising in a ladder-like manner suggestive of enteric. Beyond a white furred tongue and slight reddening of the fauces nothing abnormal was found, and all abdominal discomfort or disturbance was denied. On December 26th acknowledgement of diarrhoea led to the taking of a blood sample, the local Italian pathologist reporting the Widal test negative for Eberth's bacillus and *B. paratyphosus* B, but doubtfully positive for *B. paratyphosus* A; the blood culture was negative. There was no enlargement of spleen or liver, and the diarrhoea has at no time been accompanied by pain, griping, tenesmus, or meteorism, nor has there been excessive mucus in the stools, and only on one or two occasions undigested food particles. The pathologist reported that the stools contained fewer micro-organisms than normal, and there was no trace of typhoid or dysenteric bacilli, the majority present being diplostreptococci.

The definitely undulatory nature of the fever had become apparent by January 14th, but I rejected the diagnosis of Malta fever on the ground that it was highly improbable that it should have been contracted in London, and that the diarrhoea was unusual. On the other hand, it was difficult to assess the importance of the diarrhoea on account of the "nervous" attacks for years. As regards possibility of infection here, Malta fever seems very rare in Rapallo now, though sporadic cases occur in the port of Genoa twenty miles away.

A specimen of the stools sent to Dr. A. A. Wilson of Monte Carlo confirmed Dr. Grosso's finding of a very poor flora, but Dr. Wilson found large quantities of occult blood. As no parasites or ova were found, he concluded that the evidence pointed to some type of ulcerative colitis, though to the naked eye the stools at no time suggested this diagnosis.

On January 23rd Professor Nicola Pende came from Genoa in consultation, and thought there was some enlargement of liver and spleen, though the spleen was not palpable. He leaned towards a diagnosis of Malta fever. Dr. Grosso's report on a fresh sample of blood was as follows: Agglutination test clearly positive for two strains of *Br. melitensis* and one strain of *Br. abortus* of Bang up to a dilution of 1 in 800; absolutely negative for Eberth's bacillus and *B. paratyphosus* A and B. A day later one of the strains of *Br. melitensis* agglutinated almost completely in a dilution of 1 in 1,200.

As the *Br. abortus* of Bang belongs to the same group as the chicken cholera bacillus, and can attack the intestinal mucous membrane in man, and as Peyer's patches are not affected in Malta fever as a rule, and diarrhoea and blood in stools are infrequent accompaniments, it would seem possible that in this case there has been a double infection, with the *Micrococcus melitensis* predominating. Since the first injection of anti-*melitensis* serum the diarrhoea has completely ceased.

An interesting point is that, though the patient is always a heavy milk-drinker, all the milk consumed in London was special Grade A, and out here every drop is religiously boiled. As in the Scottish case recorded in the *Journal* of February 1st (p. 195), all attempts have failed to isolate *Br. melitensis* or *Br. abortus* from the stools.—I am, etc.,

Rapallo. DOROTHY M. ANDERSON, M.D., D.P.H.

AN OBSCURE EXANTHEM.

SIR,—During the past six to eight weeks we have met with a series of cases (about forty so far) of an infectious type which have shown symptoms that differ markedly from any of the infectious cases usually seen in general practice.

The illness sets in suddenly with pyrexia (99.5° to 102.5°), increased pulse rate, headache, nausea and vomiting, generalized pain, especially lumbar pain. There are usually no chest complications, but sometimes general abdominal pain or discomfort is present. A provisional diagnosis of influenza is made and the usual remedies are applied, but when the patient is seen again in a couple of days it is found that the pyrexia has persisted although the initial symptoms have subsided. About the fourth to the seventh day a rash appears.

The rash, which is one of the characteristic features of the illness, consists of maculo-papular spots about 1/4 in. diameter, pink in colour at first, becoming tinted with blue, then light brown, and lastly yellow, before fading. The spots are not numerous (we have counted eight in one case and as many as fifty in another), quite discrete, and easy to see. The spots come out in successive crops, so that pink and bluish and brown spots can be seen at the same time, the colour depending on the day of their appearance. The spots are most numerous on the trunk, chiefly on the front of the chest and abdomen, but have been observed also on the face, arms, and legs. The rash appears on the fourth to the seventh day, lasts about a week, and then gradually fades.

The irregular pyrexia continues during the appearance of the rash, and lasts in all from ten to twenty-one days. After the first two to three days of the illness the initial symptoms subside and the patient merely complains of general malaise and some loss of appetite. The chief features of the illness are now paucity of symptoms, persistent pyrexia with relatively slow pulse, and the curious rash above described. The illness in the first few days differs from influenza in that there is usually no bronchial catarrh or other chest complication, and only a few patients have complained of sore throat. It differs from typhoid fever in the appearance of the definite rash described above, the absence of definite enlargement and tenderness of the spleen, and the subsequent course of the illness. In several cases where the rash was not quite distinctive a Widal reaction was done and proved to be negative. A large number of our cases (over 50 per cent.) occurred in children from 8 to 14 years of age. There have been very few complications, the temperature has ultimately become normal by lysis, and after a short convalescence recovery has been complete.

We shall be glad to know what experiences other practitioners have had with similar cases; and we invite comments or suggestions as to diagnosis.—We are, etc.,

M. W. CANTOR, B.Sc., M.B., Ch.B.Glas.

London, E.1, May 5th. J. SHULMAN, M.R.C.S.

GLANDULAR FEVER.

SIR,—In the *Journal* of May 10th Dr. Letheby Tidy refers to the existence of an epidemic of glandular fever. Numerous cases of this disease, or a condition associated with glandular enlargement, are being met with in various parts of London. This epidemic, however, is of unusual interest, in that it presents features differing in many respects from most of those described in the literature.

The large number of adults in the second and third decades of life, the prolonged pyrexia, and the irregular time at which glands may first appear, are of special interest. Some of the adult cases are still running an irregular temperature after the eighth week, and in some carefully observed patients glands did not appear until the sixth to the twenty-first day, and in one instance not until the fourth week. Severe and persistent headache, frontal and occipital, has been a notable feature. Enlargement of the spleen and liver, and a rose-pink macular rash on the trunk, have been observed. While the glandular enlargement is generally limited to the occipital, posterior, and pre-auricular, submaxillary, cervical, and axillary regions, transient enlargement of those in the groin also occurs.

A definite purulent exudate on inflamed tonsils has been noted in some cases, which bacteriologically contained non-haemolytic streptococci. Although an increase in the total white cells is not always present, a considerable lymphocytosis is constant. The serum reactions for typhoid fever were consistently negative, and, where performed, those for *Br. abortus* infection were also negative. Blood cultures in a series of cases at present under observation were all negative.

Several instances of more than one case occurring in the same household have been observed, and one man contracted the disease fourteen days after his wife had a milder but definite attack. So far, no instances of infection have been noted in other patients in the ward, or in attendants and nurses. Lastly, the severity of the constitutional disturbance, as well as the prolonged pyrexial illness in many of the adults, have been disconcerting features of the present epidemic. Lobar pneumonia has been a complication in one instance. As many of the cases to which I refer are still under observation with pyrexia, it is not yet possible to give a detailed account of them.—I am, etc.,

London, W.1, May 13th. DAVID KRESTIN.

GLANDULAR FEVER AND PSITTACOSIS.

SIR,—The two letters on glandular fever and psittacosis, respectively, which appeared in the *Journal* of May 10th, prompt me to send you a reply. A study of over 3,500 cases of intestinal intoxication in man and animals has led me to conclude that glandular fever, undulant fever, psittacosis, other named and unnamed fevers, and certain cases of food poisoning have a common origin, and are not clinical or even bacteriological entities. The micro-organisms primarily responsible appear to me to be mutative forms of the non-pathogenic *Bacillus coli communis*, mostly belonging to the class known as "non-lactose fermenters." The classification is a bad one, because some of the pathogenic forms may ferment lactose. Differentiation of bacilli by means of sugar tests is always arbitrary and may be untrustworthy. Furthermore, there is no justification for assuming a homology or even an analogy between the behaviour of micro-organisms *in vivo* and their behaviour *in vitro*. The differences in the clinical pictures presented are due less to the non-lactose fermenters than to other factors. All the clinical pictures may be caused by any one of the micro-organisms in question. The other factors are altered atmospheric conditions, excessive physical and mental activity, ingestion of faulty food-stuffs, and intoxicating substances, another bacterial invasion, and the *loci minoris resistentiae* of the victim. The fevers of intestinal origin are more often due to an increased activity of the non-lactose fermenters already present than to a fresh invasion from without. Consequently it comes to pass that any factor capable of lowering the victim's resistance or of causing hydration of the protein particles in the plasma may result in an increased activity of the pathogenic micro-organisms in the intestines. The increased activity may result in no more than the protein particles in the plasma undergoing acute dehydration. Dehydration is always followed by hydration, and when protein particles undergo this chemico-physical change they are apt to become arrested and precipitated in the perivascular lymphatic vessels and capillaries. The precipitation is most likely to take place in the *loci minoris resistentiae*, and these may be the lymphatic glands in some, the lungs in some, and the skin, joints, etc., in others.

In other cases the increased activity of the non-lactose fermenters may result in the *Bacillus coli communis* multiplying elsewhere than in the intestines. When this occurs the multiplication is most likely to take place in the urogenital tract, but pyelitis and cystitis do not necessarily result. In fact, at first there is no inflammation of the kidneys and bladder, and in no instance does the so-called "infection" spread from the bladder along the ureters to the kidneys. The multiplication may occur in the blood stream, but it is incorrect to hold that the *Bacillus coli* is the cause of the trouble, and this explains why vaccines made therefrom are generally useless. Another effect is to render pathogenic certain micro-organisms which are ordinarily saprophytic, such as the streptococci and staphylococci. This may result in such clinical conditions as tonsillitis, rheumatic fever, scarlet fever, haematuria, exfoliative dermatitis, abscess formation, etc. In the last five cases of perinephritic abscess I have had, the pathogenic and causative micro-organism found in the excreta was the *Bacillus paratyphosus*.

Occasionally the offending non-lactose fermenter enters either the urogenital tract or the blood stream. In the blood stream it usually undergoes a morphological change, and it is this which has led to the differentiation of micro-organisms really closely connected. The first change is from a bacilloid to a coccoid form, and the second to a still smaller particulate form which may or may not be able to pass through a filter. The best-known coccoid form is the Brucella group of micro-organisms. These micro-organisms are, in my opinion, the coccoid form of the *Bacillus faecalis alkaligenes*, and both the coccoid form in the blood and the bacilloid form in the excreta may be encountered in the same individual in cases of glandular fever, undulant fever, psittacosis, etc. Psittacosis may occur independently of parrots or of human beings who have been in contact with sick birds, and it may, according to my experience, be caused by Gaertner's bacillus and Friedländer's bacillus. The last-mentioned micro-organism is, I believe, a mutation form of the *Bacillus coli communis*. The ultra-microscopic form may be encountered in clinical conditions other than those which can carry the label "psittacosis." The passage to which exception is taken by Drs. Bedson and Western is therefore probably correct. It adds to our knowledge to have discovered a filterable virus in certain cases of so-called "psittacosis," but it carries us no further. Indeed, it impedes us when no note is taken of its origin. Experimental work would appear to show that ultra-micro-scopic particles and particles just too big to pass through a filter may be formed not only from known micro-organi-sms but also from the victim's own protein particles. The latter may be both of haemic and of cellular origin.

The formation of ultra-micro-scopic particles is determined by many factors and may be artificially set in motion, as by altering the conditions under which the micro-organisms are growing, etc. Although all ultra-microscopic particles or virnses maintain specific features—that is to say, features peculiar to their origin—they all have certain characteristics in common. They have a strong reducing action, and function as extremely powerful dehydrators. Like all powerful dehydrators, they show a predilection for neurones, thus explaining why the mental activities are altered in cases of psittaco-is. It is interesting to note that mental depression is a sequel of most infections of intestinal origin. Had we been living twenty years ago search would have been made for spirochaetes in psittaco-is. To-day it is fashionable to look for ultra-microscopic virnses, but it does not follow because they are found that they are any more the cause of the clinical condition than that the *Spirochaeta pallida* is the cause of syphilis. Both may merely play a part, and that a subordinate one.

In what direction the search is going to be in twenty years' time it is impossible to say. It is to be hoped that the differentiation so assiduously practised will have killed bacteriology ere then and that the science will become once again part of medicine. This hope is no pious expression because new clinical conditions are in the constant process of formation. Agglutination tests are of no real value because the victim's serum may fail to agglutinate his own pathogenic micro-organisms, and agglutinate micro-organisms he neither has nor has had. It is to be deplored that what Drs. Bedson and Western decry as flights of the imagination are not more common. They are at least the products of thought, which is itself an expression of correlation, the essence of co-ordinated cerebral function.—

I am, etc.,

J. E. R. McDONAGH.

London, May 11th.

TREATMENT OF TUBERCULOUS KNEES.

SIR,—Dr. Cressy's article on tuberculosis of the knee (May 10th, p. 857) is so dangerously mi-leading that it must be answered. Perhaps I may be permitted to do so, as for the last twelve years I have had many cases under my care in the Wingfield Orthopaedic Hospital, and have discussed its treatment and end-results with Rollier, Calvé, and many American and British colleagues.

Dr. Cressy's views date from the dark ages of tuberculosis, when its diagnosis was extremely uncertain and the fundamental conditions of succes-ful treatment were undiscovered. He has apparently seen eight patients with chronic synovitis of the knee during the last forty-three years. He seems to have assumed that the knees were tuberculous, but gives no grounds for the assumption. He described (inadequately) six cases; of these, two had both knees affected, which is extremely rare in tuberculosis though common in other conditions. There is nothing in his case notes which suggests any attempt to make a diagnosis.

Dr. Cressy does not give the histories of the two knees which he amputated. One fears they were sad! For even Case 1, a girl of 18 with bilateral synovitis of the knee, had four applications of the cautery. Probably these two knees which had to be amputated were *really tuberculous*. (With modern treatment amputation is very rarely nece-sary.)

In his treatment ten days after the operation "the knee is gently bent once a day. A back splint is useful during

the first fortnight. . . . The patient is able to walk without support in about twelve weeks." A tuberculous knee treated thus will get worse, and if the treatment is continued life and limb will be endangered, for ruthless attacks on the skin and subcutaneous tissue cannot completely change the histology of synovial tuberculosis. The natural history of the healing of tuberculosis is well known; local rest and good general health of the patient maintained over a period of years are necessary. Further, a tuberculous knee is not a primary but a metastatic lesion; the patient has deep-seated glandular tuberculosis, and general treatment as well as local is necessary.—I am, etc.,

Headington, Oxford, May 12th. G. R. GIRDLESTONE.

STERILITY IN WOMAN.

SIR,—In reply to Professor Blair Bell's most interesting letter (May 10th, p. 882), I shall concentrate on the two main items of divergence between us—namely, (1) patency of the tubes in the presence of "sterility without physical signs or symptoms, or even a history indicative of the state of the tubes," and (2) the relationship of the husband to operation on the female.

Professor Blair Bell must be hard pressed for an explanation when he suggests that leakage from the joints of Bonney's apparatus is the cause of my high percentage of positive results. With his experience of an identical apparatus (I quote his own words), surely he must remember that there are only two small apertures near the apex of the hollow dilator. With these two apertures suitably controlled by the thumb and finger (either hand will do) and with full *and maintained* pressure on the bulb, the manometric needle is a certain indicator that the apparatus is intact. Further, if leakage has been a factor in my cases, why has it occurred so regularly at the different levels of pressure noted in the parous and the nulliparous?

Professor Blair Bell notes that I did not state whether a radiograph was taken to prove the passage of air in my cases, and observes that all his own cases were tested in this respect. May I remind him that, in his address, he is reported as follows (*British Medical Journal*, April 5th, p. 629): "Radiographic observation, however, is often an unnecessary refinement, for anyone experienced in the method is usually able to tell by the way the manometric needle falls after reaching about 80 mm. Hg of pressure that the air is passing into the peritoneal cavity. Moreover, it can be heard whistling through the abdominal ostia of the tubes if a stethoscope is placed on either side of the hypogastrium." I find it difficult to carry on an argument conducted on such weathercock lines. Surely Professor Blair Bell does not deny me experience in this manœuvre. I assert without any reservation that my positive results represent cases in which air *has* entered the peritoneal cavity. My negative or doubtful cases have all, where the patient was willing to submit to further investigation, been tested by lipiodol injection and radiography; it will be understood, however, that the number is remarkably small, for, in my experience, as my letter made clear, it is unusual to find blockage of the tubes either in primary or secondary sterility without some evidence of fixation of the appendages.

Wherein, then, lies the reason for the divergence in our figures? So far as I can judge, it can only arise in one of three ways: (1) The totals of one or other of us are insufficient for statistical summary; in this respect I am quite satisfied with my own numbers. (2) We differ in our appreciation of normality in the pelvis; I trust that this has always been judged by Professor Blair Bell himself. (3) Professor Blair Bell has been excluding from insufflation tests such a large number of women defined by him as cases of "hormonic insufficiency" or "constitutional disturbance" that his results have varied accordingly. I am inclined to think, and I certainly hope, that this may be the main reason, but I insist that the great majority of sterile women appear perfectly fit and present neither signs nor symptoms of one or the other. Very many of these cases present some degree of anteflexion of the cervix—a feature to which less than one line and a half was devoted in Professor Blair Bell's address, but which I believe to be a very important factor in the causation of sterility, although in no single case can one, by examination alone, affirm that it is so. The cochleate uterus is in no sense an infantile uterus (as the uterine sound will invariably demonstrate). It may be associated with some "hormonic insufficiency" in adolescence, but there is not the slightest evidence that this continues into adult life. It is not by mistaken diagnosis (as a paragraph in Professor Blair Bell's letter may suggest) that I insufflate these cases when dealing with the cervix surgically. My high percentage of positive results certainly includes many cases of the kind. Why should I neglect to do so when we are in agreement that ventilation of the tubes has its successes, and why should I not demonstrate that while anteflexion may be, infection is not, the cause of the infertility? If exclusion of cases of anteflexion of the cervix—to my mind an unjustifiable omission—be the cause of the disparity in our figures, well and good; I can imagine no other group of cases sufficiently large to affect the figures in any appreciable way.

Professor Blair Bell misrepresents my views on the involvement of the husband. Never for one moment have I doubted the wisdom of testing the husband—a step both scientific and humane. I still endeavour to do it in all private cases, but, for reasons which I gave, have ceased to insist on it. In my letter I objected to the unqualified statement that "no woman should be subjected to unpleasant examinations or treatment for sterility *per se* until her husband has been proved fertile." As Professor Blair Bell now frankly admits that many of his hospital patients *are* so dealt with, perhaps he may wish to add the qualification that should have appeared in his original address.—I am, etc.,

Liverpool, May 15th. H. LEITH MURRAY.

SIR,—I find the greatest difficulty in understanding Mr. T. C. Clare's attitude to the problem of the childless marriage when he writes in the *Journal* of May 17th (p. 927) "I therefore advocate that, except in special circumstances, the semen should only be examined when the husband asks for it." Modern research has shown that childlessness is generally due to the existence of not one but several adverse factors, and that of these adverse factors approximately two-thirds are found to exist on the female side and one-third on that of the male. The study of sterility is therefore essentially a two-patient problem, and to omit the crucial test of fertility in the male is in my opinion a definite retrograde step which I cannot too strongly condemn. And what is the reason that Mr. Clare brings forward in support of this extraordinary desire to confine our routine investigation to the wife? It is that "it is much more humiliating to the man for him (and his wife) to be assured that he is incapable of procreation than it is to the woman to be informed that she is unlikely . . . to be able to have children." And so in order to shield this poor over-sensitive man from the knowledge that his semen is poor in spermatozoa or rich in pus his wife must be subjected to an entirely unnecessary dilatation and curettage. Personally, although I have examined many hundreds of husbands from the point of view of fertility, I have never yet come across one who would rather have had useless operations inflicted on his wife than learn that his own oligospermia or azoöspermia was the chief cause of the absence of children. A man who would be plunged in the depths of despair by a decline in his sexual power can learn with equanimity that his fertility is impaired. I have no hesitation in saying that Mr. Clare is advocating not only a retrograde step in medicine, but an act of injustice for which no excuse can be found.—I am, etc.,

London, W., May 18th. KENNETH WALKER.

CAUSATION OF LEUKAEMIA.

SIR,—It is probably because of the circumstantial nature of the evidence in favour of a traumatic origin of certain cases of leukaemia that so many writers are not satisfied of its existence. Dr. Harold H. Sanguinetti, who wisely observes that the question is of more than academic interest, has brought the matter into prominence again in the *Journal* of May 10th (p. 886).

To the *Lancet* of February 8th (p. 288) I contributed an article entitled "Leukaemia following trauma," based on a case where the connexion was obviously important, and on forty others collected from the literature. In it I attempted to establish the entity, drawing upon the analogy of traumatic sarcomata of bone, suggesting the presence of a predisposition to the disease, and finally essaying, for what it might be worth, an attempt on the ultimate pathogenesis. Two other cases have come to my knowledge, the evidence, however, being less convincing. Briefly, they were both cases that developed myeloid leukaemia some years after severe war wounds, the one in the chest, the other in the thigh. In both cases bones were involved.

A point of interest on which I should like to have added support is that the cases are always of the myeloid variety (one of the cases in my series was unclassified). Since the likelihood of accidental trauma preceding the occurrence of leukaemia is equal in the two varieties, one would expect that the cases, if wrongly interpreted as traumatic leukaemia, would occur in the proportional incidence of the two varieties—myeloid and lymphatic. Does not the fact that the cases reported are always of the myeloid type negative the suggestion of accidental association? Does it not mean that the association is valid, being based on a process that, however, does not obtain in lymphatic leukaemia?

Von Domarus and others believe that the trauma only assists in bringing out the disease that was previously latent. This raises the question of what are predisposition, latent disease, and disease manifest, and where the dividing lines between them are to be placed. From the point of view of the patient the trauma marks the place between perfect health and an incurable illness; his surprise is justified when he finds disillusionment. The case I described received no compensation, but I found that two cases from the German series were granted payment and one case was refused.—I am, etc.,

London, N.W. 2, May 12th. S. CHARLES LEWSEN.

COSMETIC PREPARATIONS.

SIR,—Dr. R. M. B. MacKenna's interesting article on modern cosmetic preparations (*British Medical Journal*, May 17th, p. 899) is rather disturbing. It is alarming to think we may be daily sowing the seeds of rosacea, rodent ulcer, and epithelioma. He says: "The normal skin does require an emollient . . . normally provided by the sebum manufactured by the skin itself." But how many skins are normal? Most appear to produce too much or too little sebum, or to be unduly susceptible to infection. Numerous male skins, untouched by cosmetics, develop "scrum-pox," acne, boils, or "barber's rash"; while still more appear to suffer from excessive grease or from redness bordering on erythema (whereas in similar circumstances the female skin in its cosmetic armour usually appears cool and comfortable). Then what is to be done with the numbers of people who have from childhood a sensitive skin, which peels and chaps easily and is prone to pityriasis, and which is irritated at once by heat, cold, or drought? Hitherto I have forbidden soap and prescribed "soothing" ointments or lotions—the formulae for which I see with disquiet contain "definite irritants." With what does Dr. MacKenna treat these cases, for many must always use emollients? Can he trust preparations of lanoline or olive oil? And what does he recommend for use with massage? It would be most interesting to know.

Again, I have often been struck by the excellent skins of theatrical people, young and old, who cannot always be said to combine their cosmetic treatment to the evening, and also by the superior texture of the skins of the rich—who generally use cosmetics—to those of the poor—who used not to do so, also by the frequent occurrence of rosacea among non-cosmetic users—cooks, stokers, sailors, and others exposed to extremes of temperature (which effect might possibly have been prevented by the application of an artificial sebum in the form of a protective ointment). I should very much like to know how Dr. MacKenna explains these cases.—I am, etc.,

Tunbridge Wells, May 17th. A. MAHONY-JONES.

EARLY SIGNS OF CARDIAC FAILURE OF THE CONGESTIVE TYPE.

SIR,—In regard to the above subject I should like to draw the attention of your readers to the fact that there are a large number of patients who show a rapid pulse rate and who give high venous pressure readings, but whose hearts must be considered otherwise healthy. A young man under my observation, with a quick pulse and a suggestion of hyperthyroidism, who states that he feels quite well and is able to follow his occupation as a manual worker, shows a very high venous pressure. I have frequently found, too, high venous pressures in "soldier's" heart, etc.

I dare say that these cases are not quite up to the normal standard in their reaction to the work test, but they certainly do not suffer from any serious heart trouble. On the other hand, a patient with pronounced valvular disease, whose reaction to effort is very poor, may show a normal venous pressure. Again, I have seen a patient dying from heart disease with oedema, with a slow pulse (I suppose it will be labelled non-congestive type of heart failure), who has given a low venous pressure (see *Edinburgh Medical Journal*, November, 1928).

It is my belief that in many instances high venous pressure has nothing to do with heart disease, but is simply the result of a very short diastole which does not permit the proper emptying of the great veins of their contents into the heart; a short diastole is usually found in rapid pulse. The reader may or may not accept this explanation. The fact remains that, first, we may have a high venous pressure with a practically normal heart. Secondly, we may have a low venous pressure in a patient dying from heart failure. Thirdly, we may have a high venous pressure as a result of heart failure. It is obvious that venous pressure readings, taken by themselves, are hardly reliable criteria of heart failure (decompensation), and that little of practical importance is to be gained by making special investigations of the pressure in the veins.—I am, etc.,

Liverpool, May 14th. I. HARRIS.

ABDOMINAL PAIN.

SIR,—Mr. Zachary Cope, in his valuable contribution to this much-discussed subject (May 17th, p. 895), appears to lend the weight of his authority to a common error in the investigation of abdominal pain—namely, that psychic causes can only be diagnosed by the exclusion of organic disease. No one would deny that there are many puzzling cases that require to be submitted to the elaborate (and costly) procedure of complete examination by modern methods; but there are, I believe, few physicians of experience who would not claim the ability to recognize the existence of a psychoneurosis without any further investigations than those that can be carried out in the consulting room. Some knowledge of the fundamentals of psychopathology is as necessary to the physician who would inquire into the causes of abdominal pain as is an acquaintance with the principles of radiology.

It cannot be too strongly emphasized that the psychoneuroses give rise to positive signs, mostly of a subjective nature, which are as valuable in diagnosis as are the objective physical signs of which Mr. Cope writes with all the authority of his wide experience. Diagnosis must always ultimately depend upon positive rather than negative evidence, indispensable as the latter may be in the preliminary stages of any investigation. If it is admitted that exploration of the stomach by radiology is essential to the diagnosis of peptic ulcer it is surely not unreasonable to require a psychological exploration as a preliminary to the diagnosis of a psychic disorder. It seems to me to be particularly important at the present time that all those who have to deal with gastro-intestinal disorders should carefully reconsider the position of the psychoneurotic in relation to both diagnosis and treatment. In hospital as well as in private practice the expense of x-ray examination and other diagnostic procedures becomes increasingly important as the incomes of private patients and of voluntary hospitals yearly become less adequate. Many thousands of pounds must be wasted upon cases where

careful attention to the principles of psycho-diagnosis would result *in a definite* conclusion being reached at a single interview. The confirmation of this by a psychiatrist would entail less expense both to the hospital and to the private patient than *x*-ray and laboratory investigation.

At the risk of incurring the disasters that may follow upon skating over very thin ice, may I venture to add that this is one of those cases where the physician and surgeon are apt to differ in their outlook? The latter is mainly interested in the possibility of the relief of abdominal pain by surgery; the physician, not wedded to any special line of treatment, is primarily concerned in discovering the disorder of function which is responsible for the symptom—a disorder which may be connected with one of the systems which are usually neglected in a routine surgical examination. While not advocating a divorce of the art of surgery from that of diagnosis I feel that their continued union places upon surgeons the responsibility of appreciating that a consideration of a patient's psychology may be rewarded by positive discoveries, perhaps more often than is a physical examination of the abdomen.—I am, etc.,

London, W.1, May 19th. MAURICE E. SHAW.

TREATMENT OF GASTRIC AND DUODENAL ULCER.

SIR,—I read with interest Dr. Charles Bolton's article in the *Journal* of April 19th (p. 727) on the treatment of gastric and duodenal ulcer, and was particularly struck by his conclusion that the patient must for the rest of his life obey a strict medicinal and dietetic regime. I maintain that such a serious drawback to the normal man can be avoided by the employment of my method of posterior gastro-jejunostomy combined with jejuno-jejunostomy. After this operation a man has no need of medicinal or dietetic treatment. By this means we do not perpetuate a "physiological error" in allowing pancreatic fluid and bile to enter the stomach, but give the patient a perfectly normal digestive apparatus, with the ulcer effectually short-circuited. I appeal to surgeons to give this method a trial. A copy of my correspondence on the subject of this operation with a surgeon of the Mayo Clinic, and a report of seventy-five cases treated by him at that clinic, may be seen in the Library of the British Medical Association in Tavistock Square. A diagram of the operation appeared in the *Journal* of April 24th, 1926 (p. 738). References will be found in the *Practitioner* of June, 1920; the *Lancet*, January 21st, 1921; the Epitome of the *New York Medical Journal*, 1920; and the *British Medical Journal*, June 8th, 1929 (p. 1060).—I am, etc.,

Poole, May 7th. G. G. GILLON.

AMPUTATIONS AND ARTIFICIAL LIMBS.

SIR,—We have been interested in the report of the discussion on this subject at the Royal Society of Medicine, and also in the recent letters published in your columns. As one of the speakers suggested a closer co-operation with limb-makers, we venture to give our views from the limb-fitting aspect.

We have made and fitted thousands of artificial legs, and from the experience so gained we have formed the opinion that the true Syme's stump has been unjustly condemned. In the early days following the war we were asked to give evidence to the Ministry of Pensions regarding Syme's amputations. Our favourable opinion of these, from all points of view, was contrary to that expressed by other limb-fitting centres. An inquiry was therefore instituted at the Birmingham centre, and some twenty or so patients who had been fitted by us were instructed to attend. The following results were found:

1. In all cases the men were comfortable and were wearing the foot regularly.
2. No case of stump trouble was found.
3. The initial cost of the limb and of its subsequent upkeep were very much smaller than in the case of any other limb.
4. Walking ability and length of use per day were found to be greater than with any other artificial limb.

In civil cases we have also had opportunities of seeing the results. We have had cases of double Syme's; one patient, in particular, has worn limbs for thirty years. At a later period than the inquiry referred to above the modified Syme's amputations were performed, partly, we think, from a desire to improve the shape of the stump and give it a less bulbous appearance. This, and so-called Syme's amputations which were made *above* the malleoli probably accounted for the stump trouble and re-amputations. The natural heel-pad is the best form of end bearing, the bulbous end of a good Syme's being of great service in preventing any lifting movement in the artificial limb sockets when walking. Again, the enlarged end makes artificial joints and thigh corsets unnecessary. These advantages far outweigh aesthetic drawbacks. In this connexion we would recall an article published in February, 1922, by Mr. S. T. Irwin, on the relative values of various amputations of the lower limb, from the point of view of artificial legs. He gave numbers denoting respective values in capacity of work. In his list the Syme amputation was given second place, the first being taken by amputation of toes only.

One of the chief difficulties with which a limb-maker has to contend is the length of time after the stump has healed before a limb is fitted. An idea seems prevalent that if left for a long time shrinkage will take place. Shrinkage can only be brought about, as a rule, by the wearing of a pylon or artificial leg. Generally, during the period of waiting, the hip-joint in cases of thigh amputation, and the knee in cases of below-knee amputation become partly flexed owing to the way the patient carries the stump when using crutches. This greatly increases the limb-fitter's difficulty in obtaining good results.—We are, etc.,

Birmingham, May 14th SALT AND SON, LTD.

DEATH UNDER SPINOCAIN ANAESTHESIA.

SIR,—Replying to Mr. A. Wilfrid Adams's question (*Journal*, April 19th, p. 760) I have pleasure in giving him the details for which he asks.

The patient was not operated on by myself, but by another surgeon, who has kindly furnished me with the following. Without withdrawing any cerebro-spinal fluid 2 c.c. spinocain were injected into the third to fourth lumbar interspace, and the head was lowered immediately about 30 degrees. The patient had no carditis and no intestinal obstruction, but was very anaemic, for which blood transfusion was performed. The anaesthesia was of the combined type, so the upper level of cutaneous anaesthesia was not ascertained. In my first communication of this case (April 12th, p. 693) the error of the site of the injection was entirely mine.—I am, etc.,

Victoria, British Columbia, April 30th. A. B. HUDSON.

"BIOLOGICAL REVERSION AND HIPPOCRATIC ANATOMY."

SIR,—In your review published on April 26th (p. 786) a single description is quoted which was commented on as follows: "One may be excused for mistaking this for pure osteopathy." The description deals with perithecal tension, an anatomical fact first defined and described by Professor Jean Sicard to account for the presence of albumin in the cerebro-spinal fluid due to venous obstruction. Further clinical research, based on the rigid disciplines of anatomy, enabled him to diagnose perithecal tension in six cases of intractable lumbago which were operated on by M. Robineau by laminectomy. "When the vertebral canal was opened and the perithecal fat exposed it was found to be tightly packed and to project like india rubber out of the vertebral canal. When it was removed the cord and the nerves were found to be compressed and displaced." It was owing to the instruction of my late friend Professor Sicard, in his rigid anatomical technique that my own vertebral researches were undertaken more than twelve years ago. Variations in this tension have been examined for months almost daily.—I am, etc.,

Brighton, May 19th. HUBERT HIGGINS.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons this week read the Finance Bill a second time. Unemployment was debated on the vote for the department of the Lord Privy Seal. The Estimates for Agriculture and Scotland were also in the week's business.

Consideration by the House of Lords of the Commons amendments to the Mental Treatment Bill has been fixed for May 29th.

In the House of Lords, on May 19th, the Illegitimate Children (Scotland) Bill and the Hairdressers' and Barbers' (Sunday Closing) Bill were read the first time. These bills had been read a third time by the House of Commons on May 16th.

On May 20th the Parliamentary Medical Committee decided to ask the Minister of Health to establish a standing advisory committee on clinics for rheumatism. On the same evening the committee was addressed by Dr. Copeman, one of the physicians in charge of the Red Cross clinic for rheumatism at Regent's Park.

Mental Treatment Bill.

As recorded in our issue last week, the Mental Treatment Bill passed through report and third reading in the House of Commons on May 15th. The earlier portion of the debate has already been reported.

On Clause 11, which dealt with the reorganization of the Board of Control, Dr. FREMANTLE moved an amendment to provide that the clause should read as follows:

"The Board of Control shall consist of the chairman (who shall be a paid Commissioner) and not more than four other Commissioners all of whom shall be paid Commissioners, and two unpaid Commissioners, of whom one shall be a layman and the other a laywoman."

He said that the Board of Control was being radically changed. The bill suggested that all the five members of the new Board of Control should be paid members. That cut out the unpaid Commissioners, who had done such good work hitherto at the Board of Control, and to make assurance doubly sure, a clause later in the bill said that there should be no unpaid Commissioners. There was nothing to that effect in the report of the Royal Commission, and one had to look further afield for the reason for cutting out the unpaid Commissioners. The unpaid Commissioners at present were reckoned to be doing good work. The actual numbers had come down to two. It was said that in future this work was to be done by the paid Commissioners, that the paid Commissioners were to be civil servants, and that the work was to be systematized and brought under control. It was for that reason that he proposed, in this amendment, that there should be one unpaid layman and one unpaid laywoman to bring in the unofficial element. The gist of the proposal was that there should be an unpaid official element to bring the point of view of the ordinary man and woman into the working of the Control Board. It had been clearly shown that there was a great suspicion and distrust of the official element in dealing with the question of mental disorder, and quite naturally and rightly so. They were touching the very basis of human life, and there were innumerable opportunities for things to go wrong. They wanted to establish public confidence and show that there was not going to be the iron grip of officialdom on the unfortunates who were being dealt with by this system of mental supervision and treatment. The bringing in of the human factor of the unpaid man and woman into the vital part of the machine, the Control Board, would give confidence to the public that the Board of Control was still human, in spite of the fact that it was official. It was no insult or reflection on the officialdom of the Government service to say that it still required this element. The proposal in the bill, without the unpaid element, created the greater difficulty that the functions were being divided. The Board of Control was to sit in Whitehall while the Commissioners were visiting. It was only for very special purposes that the Board of Control would be expected to spare time to visit. The unpaid man and woman would be able to do a good deal of the visiting and introduce the needs that were required. Those who had seen the unpaid visiting committees of county councils, or people like the Commissioners, at work in the mental hospitals could realize the value of their work. Simply because they were unofficial and unpaid, they could often get into closer touch with the patients and the staff in a way the officials were not able to do.

Dr. VERNON DAVIES, who seconded the amendment, said that the Board of Control had for years been gaining more and more the confidence of the public. They occupied a very special and peculiar position. They were the only safeguard that mental patients had against improper or illegal detention. Nothing would give the people more satisfaction than the knowledge that on the Board of Control there were two lay unpaid persons to look after the interests of the patients. The fact that these two people were unpaid would show that they were absolutely unprejudiced and under no departmental influence. The duties of the Board of Control were very valuable and varied. Under the bill the Board was simply going to become a department of State. He believed it was the idea of the Minister and the department that it should become a department of the Ministry of Health. The unpaid Commissioners would be a very strong safeguard that the Board did not become so departmentalized that the people of the country could not get to know what was really happening.

Mr. GREENWOOD said that he could not accept the amendment. He was of the same opinion as in the committee stage, that this principle of unpaid Commissioners really introduced an element that was foreign to the spirit of the Royal Commission. The Royal Commission anticipated a small body of full-time people running an administrative machine. The supporters of the amendment wanted a Commission larger than that recommended by the Royal Commission, with two unpaid people in it, for no other purpose than to make it a body less responsible to the Minister than the Royal Commission ever had in mind. In the early stages of the bill a strong view was expressed, not that this body was subservient to the Minister, but that it was far too independent of the Minister. The case which he had made, time after time, was that in these proposals it would be possible to get a closer contact between the Minister and administrative machinery than was possible in cases where they had unpaid people. The Royal Commission never wanted a body that was more independent. It wanted a more effective administrative machine. No one would ever persuade him that they would have a machine that was effective if it was established partly of volunteers. (Cries of "Oh!") Clearly, what members opposite wanted was a semi-independent body over whom no one was going to have control. The argument that had been repeatedly levelled against the Minister and the Board of Control was that this body, as constituted to-day, was utterly out of touch with the public, and had lost public confidence. To-day it contained people who were unpaid Commissioners. He saw no reason to believe that, if public confidence had been forfeited, it would be restored by people who were there to-day. No other department in the State placed heavy executive and administrative responsibilities on an honorary staff, and there was no reason why they should have it in the Board of Control. The fact that they had two people, a man and a woman, from whom they could not make demands, but to whom they could make requests, was not going to make a difference to the spirit of the Board of Control. Members opposite were pressing the amendment, not because they wanted more direct public control over the Board, but because, apparently, they wanted less. The amendment would be injurious to the interests of mental treatment.

Mr. E. BROWN said that the Minister's speech really drove him in favour of the amendment, for if that was the outlook of the Minister of Health and his department the sooner the House took note of it the better. He objected to the tenor of the speech.

Miss RATHBONE said she had listened with dismay to Mr. Greenwood's speech. The fact that he had laid so much stress on the Board of Control being an entirely paid Board in order that it should be directly responsible to the Minister was precisely what the public did not want. It was rather ungracious of the Minister to go out of his way to allude to the unpaid Commissioners, and say that the Board had lost the confidence of the public.

The amendment was defeated by 163 votes to 63.

Dr. FREMANTLE moved an amendment providing that two of the senior Commissioners should be medical Commissioners, which was accepted by Mr. Greenwood.

An amendment by Dr. FREMANTLE, that the paid Commissioners, other than the senior Commissioners, should be appointed by His Majesty on the recommendation of the Board of Control, was defeated.

Miss LAWRENCE moved to leave out para. 2 of Clause 16, which deals with proceedings taken against a doctor, and to substitute the following words:

"(2) No proceedings, civil or criminal, shall be brought against any person in any court in respect of any such matter as is mentioned in the last preceding sub-section, without the leave of the High Court, and leave shall not be given unless the court is satisfied that there is substantial ground for the contention that the person, against whom it is sought to bring the proceedings, has acted in bad faith or without reasonable care.

"(3) Notice of any application under the last preceding sub-section shall be given to the person against whom it is sought to bring the proceedings, and that person shall be entitled to be heard against the application.

"(4) Where on an application under this section leave is given to bring any proceeding, and the proceedings are commenced within four weeks after the date on which leave was so given, the proceedings shall for the purposes of the Public Authorities Protection Act, 1893, be deemed to have commenced on the date on which notice of the application was given to the person against whom the proceedings are to be brought."

She said that the Royal Commission pointed out that the protection allowed by the law to medical men against whom proceed-

ings were taken was not sufficient, and many doctors would not sign certificates on account of the difficulties in which they might be landed. The Government resolved to carry out the recommendations of the Royal Commission, and inserted a form of words that was discussed in committee. As a result of that discussion the Minister of Health promised to meet some of the difficulties and objections raised. The Government had very considerably amended the original clause, which provided that the doctor was obliged to apply to the judge for a stay of proceedings. In this new clause proceedings might be conducted in a more appropriate way. Before an action began, a judge had to be satisfied that there was substantial ground for it. Many people who had undergone treatment had been discharged partially cured, and they were unfortunately very likely to take legal proceedings. Mr. Somerville Hastings, in the second reading discussion, had said that there were two classes of insane people, and that one of them included those people who never believed them and bore a grudge against everyone. It was quite likely that there might be a mass of baseless actions against doctors, and the Government had provided that leave must be given for the initiation of such proceedings against a medical practitioner. That was the main change that they had made in the bill, and she hoped that its new form would meet the apprehensions that were expressed by hon. members.

The amendment was agreed to, and the report stage was concluded.

On the motion for the third reading,

Dr. VERNON DAVIES said that the bill, which would affect thousands of people, had been passed through the House with a minimum of discussion and a maximum of forced closure. They had not been able to do justice either to themselves or to the people whom they represented. It was useless to say that the Opposition regarded the bill as satisfactory. They had the greatest hopes on the second reading. They visualized that there were great opportunities for this class of patient if they could get them in the early stages of disease. In the committee stage they were strongly desirous of helping. Some of the medical men, who had a certain knowledge of what they were talking about, found the Minister of Health and the Parliamentary Secretary most determined opponents of what they proposed. There were many provisions in the bill which were not going to act as they wanted them to act. The bill would be detrimental to the treatment of mental disease. It would prevent some of these people submitting themselves for treatment as early as they should do. The obstinacy of the Minister in refusing to accept change with regard to the Board of Control would have a detrimental effect. People were going to be more suspicious of the Board of Control than ever in the past. They would regard it as a Department of the Ministry of Health. Labour members simply jeered at the medical profession. They thought that their motives were not of the best and purest, and imputed to them unworthy motives. It had constantly been done in that House. The medical profession had been more or less the butt of the Labour party. They had not remembered that the health of this country was in the hands of the medical men, and that people's opinion regarding the medical men of the country was not improved by constant ill-informed criticism. Members who had had the opportunity of expert advice from men who had no axes to grind, and who had retired from practice, had, by their rigid adherence to the party whip or blindly following a department, passed on to the Statute Book a bill not half so good as it might be. Nevertheless, he hoped that the bill would give some relief to the poor people of the country.

Mr. WINTERTON said that of all people who had the right to complain the medical profession had the least. The bill would probably never have seen the light in that House except for the demand of the medical profession that they might be relieved of certain obligations which most other professions were willing to accept. In the bill the privileges of the ordinary individual were invaded to give extra privileges to the medical profession and place them in an entirely privileged position, which no other profession had ever asked for. If he could feel sure in his heart that the patients who would come for treatment under the bill were as secure as were the doctors he would feel a great deal happier about it. It came with ill grace that those who had got so much out of the bill and had supported it through thick and thin against the liberty of poor people should now complain that they had not enough.

Dr. MORRIS-JONES said he felt sure that this was a very excellent bill, and he congratulated the Minister of Health on getting it through. It was a great charter for the poor of the country, and for the first time it gave them as great a chance as the rich. He could not quite agree with Mr. Winterton, who talked about the privileges of the medical profession. He denied emphatically that there was anything in the bill which conferred any privileges on the profession in any shape or form. The bill got away from the spirit of detention to that of prevention and treatment. When the bill came to be adopted and understood in the country it would be successful.

The bill was then read a third time.

Fibrosis of the Lungs in Miners.—Replying to Mr. Hopkin, on May 15th, Mr. CLYNES said the expert committee of the Medical Research Council would be asked to consider the extension of the research into causes of fibrosis of the lungs of miners in the anthracite district, which had been organized by Professor Cummins, director of the Welsh National Memorial Association. The Council had already made a grant for the expenses in connexion with research at this laboratory.

Radium.—On May 15th Mr. GREENWOOD told Commander Bellairs that the radium purchased by the Radium Trust and Radium Commission had so far been obtained on "most favoured nation" terms.

Vaccination Order, 1929.—Sir C. TREVELYAN, on May 7th, in reply to Mr. Groves, said that it was unnecessary to call the attention of the governors of State-aided schools to the Ministry of Health's Vaccination Order of October 1st, 1929. This Order was to the effect that so long as the small-pox prevalent in this country retained its mild character it was not generally expedient to press for vaccination of persons of school age or adolescents who had not been previously vaccinated, unless they had been directly exposed to small-pox infection. This Order had, in Sir Charles's opinion, received sufficient publicity.

Grants to Maternity Hospitals. Mr. GREENWOOD informed Major Carver, on May 15th, that under the new system of payment grants to maternity hospitals would be made in their entirety for 1929, so that there would be no gap between the Ministry of Health's payments and payments by the local authorities concerned.

Manufacture and Distribution of Quinine in India.—Mr. BENN told Major Pole, on May 15th, that he had not yet received a report from the Government of India on cultivation of cinchona and the manufacture and distribution of quinine in India. The Government of India was in consultation with the provincial Governments on the question of centralizing the whole subject of cinchona cultivation and the manufacture and distribution of quinine. This would be the first step towards reducing the price of quinine.

Foot-and-Mouth Disease.—Mr. NOEL BUXTON told Dr. Fremantle, on May 15th, that he had learnt of a reported discovery in Buenos Aires of an effective vaccine against foot-and-mouth disease, and was making inquiries.

National Health Insurance: Valuation of Approved Societies.—In a reply to Mr. Rhys Davies, on May 16th, Mr. GREENWOOD said the valuation of the first group of approved societies and branches under the national health insurance scheme, made as at December 31st, 1927, had now been completed. Progress was being made with the second group, valued as at December 31st, 1928, and he hoped the results would be available about the end of 1930. The results of the valuation of the last group should be available about a year later.

Pensions.—Mr. F. O. ROBERTS, replying to Sir A. Pownall on May 19th, said that of 318 applications for pensions outside the seven years' limit dealt with since last November, 300 were given pecuniary compensation. The remaining 18 needed only a brief course of treatment.

Obituary.

DR. CHARLES JOHN BATTLE of Klerksdorp, Transvaal, died on March 19th, at the age of 50, after an illness lasting two months; he was the son of the late Mr. Charles Key Battle, and nephew of Mr. W. H. Battle, consulting surgeon to St. Thomas's Hospital. Charles Battle received his medical education at St. Thomas's, and obtained the diplomas M.R.C.S., L.R.C.P. in 1903, after which he practised for some time in Natal and also on the East Rand. During the war he served in East Africa with a commission in the South African Medical Corps. He then commenced practice in partnership with Dr. Orford in Klerksdorp, where he held the appointments of medical officer of health, medical superintendent to Klerksdorp Hospital, district surgeon, and railway medical officer. His special diagnostic ability, his energy, and his unselfish devotion to those he served, won for Dr. Battle high esteem and deep affection, and sincere sympathy is felt for his widow and his mother. He was a member of the British Medical Association.

The following well-known foreign medical men have recently died: Dr. BOEZ, director of the Pasteur Institute at Saigon; Dr. LOUIS CHARLES LEHR, emeritus professor of genito-urinary surgery at Georgetown University School of Medicine, aged 54; and Dr. DAVID HUMMEL COOVER, emeritus professor of ophthalmology, Colorado University School of Medicine, aged 77.

The Services.

TERRITORIAL DECORATION.

THE Territorial Decoration has been conferred upon Lieut.-Colonels H. E. McCready, *M.C.*, and J. D. Comrie (ret.), under the terms of the Royal Warrant of October 13th, 1920.

DEATHS IN THE SERVICES.

Surgeon Major Alexander Gamack, Madras Medical Service (ret.), died at Hampstead on March 8th, at the great age of 98. He was born on February 13th, 1834, the son of William Gamack, solicitor, of Peterhead, and was educated at Aberdeen, where he graduated as M.A. in 1853 and M.D. in 1856 of Marischal College, also taking the L.R.C.S.Ed. in 1856. Entering the I.M.S. as assistant surgeon on August 4th, 1856, he became surgeon major on July 1st, 1873, and retired on August 1st, 1879, over half a century ago. Most of his service was spent in civil employ in the Madras Presidency, where he was for many years civil surgeon of Madura. He was, of course, the oldest I.M.S. officer on the retired list, and was the last survivor of the company's medical officers.

Dr. Charles Frederick Kennan Murray, O.B.E., late surgeon R.N., died at Pulmet, Elgin, Cape Colony, on March 7th, aged 81. He was born in Wicklow on September 27th, 1848, and was educated in Dublin, graduating as M.D. in 1868, M.Ch. in 1884, and M.A.O. in 1896 of the Queen's University, Ireland; and also took the L.R.C.S.I. in 1867 and the F.R.C.S.I. in 1884. In August 1889, he entered the Navy as surgeon, and served on H.M.S. *Rattlesnake*, the flagship of Sir Edward Commerell, V.C., R.N., in the Ashanti war, when he served in boat work on the River Prah, and attended the admiral when he was wounded, also being wounded himself. He was mentioned in dispatches, and received the Ashanti medal. In 1892 he resigned the Navy and settled in Cape Colony, where he married the second daughter of the late Sir John Charles Molteno, K.C.M.G., the first premier of Cape Colony. He was the first president of the Colonial Medical Council, and was unanimously re-elected to that office for twenty-seven years. He was for many years surgeon to the Victoria Cottage Hospital, Wynberg, and consulting surgeon to Somerset Hospital, Capetown. When the war of 1914–18 began he undertook the sole charge of a large practice to free his son, Dr. Kennan Murray, for service in the South African Field Ambulance in France, and also served in a local military hospital, receiving the O.B.E. after the war.

Colonel John Francis Williamson, C.B., C.M.G., formerly of the R.A.M.C., died at Dover in the first week of March, aged 79. He was born at Glasslough, Monaghan, on February 6th, 1851, the son of the Rev. A. Williamson of Ardess, Fermanagh, and was educated at Trinity College, Dublin, where he graduated as M.B. and L.Ch. in 1876. Entering the Army as surgeon on February 4th, 1879, he attained the rank of colonel on November 20th, 1903, and retired on February 6th, 1906. He received the C.M.G. in 1901, the C.B. in 1904, and a distinguished service pension in 1910. He had a very long list of war services: Afghanistan, 1878–79, battle of Charasiab, action on Kabul Heights, defence of Sherpur cantonments, the march under General Roberts from Kabul to the relief of Kandahar, when he served with the Seaforth Highlanders, and battle of Kandahar; mentioned in dispatches in the *London Gazette* of December 3rd, 1880, medal with three clasps, and bronze star. Egypt, 1882, battle of Tel-el-Kebir, medal, and Khedive's bronze star. Burma, 1887–88, North-West frontier of India 1897–98, Mohmand and Tirah expeditions, mentioned in dispatches in *London Gazette* of January 11th, 1898, medal with two clasps. South Africa, 1899–1902, in charge of a general hospital, operations in Cape Colony, mentioned in dispatches in *London Gazette* of April 16th, 1901, Queen's medal with 5 clasps, King's medal with two clasps, C.M.G. East Africa, 1903–4 operations in Somaliland, as principal medical officer, mentioned in dispatches by General Manning, August 17th, 1903, and General Sir C. C. Egerton, May 30th, 1904, and in *London Gazette* of September 2nd, 1904, medal with clasp, and C.B.

Lieut.-Colonel George Hart Desmond Gimlette, C.I.E., Bengal Medical Service (ret.), died at Southsea on March 7th, aged 72. He was the eldest son of the late Fleet Surgeon Hart Desmond Gimlette, R.N.; Surgeon Rear-Admiral Sir Thomas Desmond Gimlette, K.C.B., R.N. (ret.), was his brother. He was born on September 8th, 1855, at St. Aubyn, Stoke Damerel, was educated at St. Thomas's, and took the M.R.C.S. and L.S.A. in 1877, also graduating as M.D. and M.Ch. in the Royal University, Ireland, in 1879. Entering the I.M.S. as surgeon on March 31st, 1879, he became lieutenant-colonel after twenty years' service, was placed on the selected list for promotion on June 16th, 1905, and retired, with an extra compensation pension, on April 1st, 1910. He served in the Egyptian campaign of 1882, when he took part in the action at Tel-el-Kebir and pursuit to Zagazig, and received the medal and the Khedive's bronze star. In 1883 he was one of the medical officers deputed from India to work in the cholera epidemic which was then devastating Egypt. Towards the end of that year, on his return to India, he joined the Political Department, in which the rest of his service was spent, and was posted as Residency surgeon to Katmandu, the capital of Nepal. In 1891 he became Residency surgeon of Baghelkand, and in 1897 of Indore, where he was also P.M.O. of Central India. In 1901 he was appointed Residency surgeon of Haidarabad, then considered the best executive appointment held by any medical officer in India, and kept that post till his retirement. When the war of 1914–18 started he at once rejoined for service, and as P.M.O. of the Indian hospital ship *Sicilia* for over two years, made many trips to France, Egypt, and Gallipoli. In 1917 he rejoined for service in India, and was re-employed there for some time as Residency surgeon of Maisur, but later in that year went to Iraq on military duty. In 1901 he was given the C.I.E. He was the author of a work entitled *A Postscript to the Records of the Indian Mutiny*, 1927. While Residency surgeon of Nepal, and *ex officio* Assistant Resident, an experience fell to his lot which probably no other medical officer ever shared. The Indian Government maintained at Katmandu a small corps of two hundred men, called the Resident's escort. It was the custom for the Resident to make a tour along the Nepalese frontier in the cold weather, taking half the escort with him, the other half remaining at Katmandu, with the Assistant Resident, who was in charge during his chief's absence. In 1925, while the Resident was on tour, a revolution broke out in Nepal, which was completely successful, the insurgents seizing the Government and killing all of their chief opponents whom they could catch. Some of the defeated leaders took refuge in the Residency. The leader of the victorious revolutionists demanded their surrender, which of course meant their immediate execution, and Gimlette had to make up his mind at very short notice whether he would comply with the request, and give up the refugees to their deaths, or defy the victorious party and refuse, staking his own life, and the lives of all in the Residency, on the hope that the revolutionary leaders would realize the rashness of an attack on an English Residency. Of course, the small escort could have put up no effectual fight against the revolutionists, but could only have defended the Residency to the death. Fortunately the successful leader had the sense to see that an attack on the Residency, however successful for the moment, meant war with England, and probably the end of Nepal; and was also strong enough to restrain his followers. No attack was made on the Residency, the refugees were protected, and in the end were safely passed down under escort into British India, and interned at Benares. Colonel Gimlette was unmarried; he leaves two surviving brothers, Surgeon Rear-Admiral Sir Thomas Desmond Gimlette, K.C.B., R.N. (ret.), and Dr. J. D. Gimlette, and three sisters.

Universities and Colleges.

UNIVERSITY OF OXFORD.

George Herbert Hunt Travelling Scholarship.

THE electors of the George Herbert Hunt Travelling Scholarship have awarded the scholarship for 1930 to Ronald Graeme Macbeth, B.M., Oriel College.

UNIVERSITY OF CAMBRIDGE.

THE Council of the Senate has appointed Professor H. R. Dean, M.D., a member of the Council of the Lister Institute of Preventive Medicine for ten years.

At a congregation held on May 16th the following medical degrees were conferred:

M.B., B.CHIR.—J. V. Broad, E. C. Wynne-Edwards, E. R. Keeble.
B.CHIR.—L. J. Hardon.

UNIVERSITY OF LONDON.

THE ceremony of presentation day was held on May 14th. There was an academic procession from the Imperial Institute to the Albert Hall, in which the Chancellor, Lord Beauchamp, the Senate, and officers of the University took part. The Lord Mayor of London and the Lady Mayoress were among the guests assembled in the hall. The Chancellor in his address referred to the fact that that was the first meeting of the kind under the new constitution created by the new statutes made by the Commissioners under the University of London Act of 1926. After welcoming the guests he expressed regret at the approaching resignation of the Vice-Chancellor, Sir Gregory Foster. The total number of candidates for all examinations was 36,633, as against 34,941 in the previous academic year, and 11,937 in 1913. Of the 3,946 candidates for degrees, 2,458 were internal and 1,488 external. The total number of successful candidates at all examinations was 15,793, and of those who obtained degrees and diplomas 3,036, as compared with 15,186 and 3,039 respectively in the previous year. The roll of internal students now comprised 10,200 names, as compared with 4,950 on the corresponding date in 1914 and 9,886 in 1929.

At the service held in Westminster Abbey the sermon was preached by Canon C. E. Raven of Liverpool.

The graduation dinner was held in the evening at the Fishmongers' Hall, when the Chancellor presided. The toast of "The University" was proposed by the Prime Minister, who said that while many colleges and universities have been founded by benefactors, the London University was founded by a high idea. The University had gone from strength to strength, and it had the largest number of students of any university in the country. He expressed his great interest in the Post-Graduate Medical School proposed to be founded in connexion with the University. The Chancellor, in acknowledging the toast, stated that the University had on that day 11,000 students reading for their degrees. The toast of "The New Graduates" was proposed by the Archbishop of Canterbury, who congratulated the University upon the great strides it had made.

UNIVERSITY COLLEGE.

A public lecture on the secretory action of the nervous system will be given by Professor G. H. Parker of Harvard University on Friday, May 30th, at 5.30 p.m. The chair will be taken by Professor D. M. S. Watson, F.R.S. The lecture is open without fee to students of the University and others interested in the subject.

UNIVERSITY OF MANCHESTER.

THE Council has gratefully accepted the offer of the Manchester Medical Society to present to the University its medical library, which has been housed in the University since 1875, and for a number of years has been supported jointly by the Manchester Medical Society and the University. Provision has been made for the members of the Manchester Medical Society to continue their use of the medical library, and the society has undertaken to make an annual grant towards the cost of maintenance.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

AT a meeting of the Royal College of Surgeons of Edinburgh held on May 15th, when Dr. James Haig Ferguson (President) was in the chair, the following 21 successful candidates, out of 68 entered who passed the requisite examinations, were admitted Fellows:

S. Annaswami, D. J. Brown, E. J. Burton, A. B. Cook, J. E. Erdheim, M. Husnain, F. W. Holmore, K. L. H. Kirkland, D. A. Langhorne, Shu Pui Li, J. C. McMaster, C. D. Meadowcroft, Marjorie Murrell, James Purce, A. D. D. Pye, Marion A. Radcliffe-Taylor, J. F. Robinson, J. B. de C. M. Saunders, A. B. Smith, R. F. Ward, D. Wilkie.

Bathgate Memorial Prize.

The Bathgate Memorial Prize, consisting of bronze medal and set of books, after a competitive examination in materia medica, has been awarded to Mr. G. L. G. Major.

Medical News.

PROFESSOR LEONARD HILL will deliver the annual oration of the St. John's Hospital Dermatological Society on May 28th, at 5 p.m., at St. John's Hospital, 49, Leicester Square, his subject being the penetration of the skin by radiation. On the evening of the same day the annual dinner of the society will be held at Kettner's Restaurant at 6.45 for 7 p.m.

THE summer sessional address before the Abernethian Society of St. Bartholomew's Hospital will be delivered by Sir Archibald Garrod on Thursday, June 5th, at 8.30 p.m. The subject will be "St. Bartholomew's fifty years ago."

AN open-air lecture on "Cabbages and kings" will be given at the Chelsea Physic Garden, Swan Walk, Chelsea, by Dr. A. W. Hill, director of the Royal Botanic Gardens, Kew, on Thursday, May 29th, at 5 p.m. Sir William Collins, chairman of the Chadwick Trustees, will preside. Information about Chadwick Public Lectures may be had from the secretary, Mrs. Aubrey Richardson, at the offices of the Trust, 204, Abbey House, Westminster, S.W.1.

THE sixth annual meeting of the National Institute for the Deaf will be held at the Church House, Westminster, S.W.1 (entrance, Great Smith Street), on Friday, May 30th, at 3 p.m., under the chairmanship of Lord Charnwood. The Rt. Hon. Stanley Baldwin, M.P., will speak.

A MEETING of the International Pharmaceutical Federation will be held at Stockholm from July 16th to 18th, when the following subjects will be discussed: nomenclature of new drugs, international formularies, control of specialties, influence of industry on pharmacy, standardization of drugs, and supply of drugs to ships.

THE Fellowship of Medicine announces that two free demonstrations will be given at the Miller General Hospital, Greenwich; on Monday, May 26th, at 2 p.m., Dr. E. C. Warner will describe selected cases of disease in children, and on Friday, May 30th, at 2 p.m., Mr. Arthur Gray will demonstrate gynaecological operations. Dr. B. T. Parsons-Smith will deliver two lectures especially suitable for the M.R.C.P. at the Medical Society of London, 11, Chandos Street, Cavendish Square, both at 8.30 p.m.; on Tuesday, May 27th, he will discuss coronary thrombosis, and on Friday, May 30th, cardiac failure. From May 26th to June 7th there will be a morning course in diseases of children at the Hospital for Sick Children, Great Ormond Street, and an all-day course in medicine, surgery, and the specialties, with especial reference to tuberculosis, at Queen Mary's Hospital, Stratford. Courses in June will be as follows: [illegible] Hospital for Women, June 16th [illegible] Blackfriars Skin Hospital, June [illegible] medicine and surgery at the Prince of Wales's Hospital, all day, June 16th to 28th; and proctology at St. Mark's Hospital, all day, June 30th to July 5th. Copies of syllabuses and particulars of all post-graduate work are obtainable from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A POST-GRADUATE lecture on elective localization of streptococci following their inoculation into the teeth of dogs will be delivered at the Royal Dental Hospital of London School of Dental Surgery, Leicester Square, W.C., by Dr. E. C. Rosenow of the Mayo Clinic, Rochester, U.S.A., on Monday, May 26th, at 5 p.m. Admission is free.

AT a meeting of the Royal Society on May 22nd Dr. H. H. Dale communicated a paper by Professor G. H. Parker of Harvard on ciliation of the Fallopian tubes. Sir Charles Sherrington communicated a paper by Mr. H. E. Roaf on visual acuity in light of different colours. A joint paper by Sir Charles Sherrington and Mr. J. C. Eccles on numbers and contraction values of individual motor units examined in some muscles of the limb was read in title only. Before the meeting Professor Elliot Smith showed a cast of the Peking skull.

A SPECIALLY conducted visit to the new dock at Tilbury, and the Orient liner *Orontes*, will be made on Friday, June 20th, in aid of King Edward's Hospital Fund for London; a steam launch will leave Westminster pier at 9.30 a.m. Lunch will be served on board the *Orontes*, and afterwards representatives of the Port of London Authority will demonstrate the new dock. Tickets, price one guinea, can be obtained from the secretary of King Edward's Hospital Fund for London, 7, Walbrook, E.C.4. Early application should be made as the number of the party is limited.

THE fifth International Congress of Physiotherapy will be held at Liège from September 14th to 18th, and not as announced in the *Journal* of May 17th. Twenty-five countries have already appointed national committees, and the particular subjects to be discussed will be: the rôle of physiotherapy in the treatment of rheumatic disorders; physiotherapeutic treatment of the disorders of the central nervous system; and the university tea[illegible] There will be sections dealing with [illegible] education, radiology, electrology, and thermotherapy, hydrology, and actinology. Following this congress the second annual meeting of the International League against Rheumatism will be held in Liège from September 18th to 20th, and members of the congress will be allowed to take part in all its meetings. Travelling concessions have been sanctioned by the French and Belgian Governments in connexion with the congress, further details of which may be obtained from Dr. W. Kerr Russell, 126, Harley Street, W.1.

THE first Congress of the International Society of Experimental Phonetics will be held at the University of Bonn from June 10th to 13th. Physicists, medical practitioners, dentists, linguists, and teachers are invited to attend. The subscription is ten marks. Further information can be obtained from the Phonetisches Institut der Universität Bonn, Poppelsdorfer Allee 25, Bonn.

THE first Transcaucasian Congress of Obstetrics and Gynaecology will be held in Tiflis in September, when the following subjects will be discussed: the pelvis in the Transcaucasian races, treatment of inflammation of the adnexa, pregnancy and infectious diseases, obstetrical assistance, and gynaecological prophylaxis and treatment in the Transcaucasian Republic.

THE eleventh salon des médecins for the exhibition of works of art by medical practitioners, dentists, veterinary surgeons, and members of their families will be held at 117, Boulevard St. Germain, Paris, on June 24th. Further information can be obtained from Dr. Paul Rabier, 84, Rue Lecourbe, Paris, XVe.

THE Mothercraft Lending Library (16, Porchester Square, London, W.2) has issued a catalogue (price 6d.) of books on infant feeding and care, child training and education, diet and food values, and nursery management and hygiene, and allied subjects. Parents, nurses, and child educationists for a subscription of 10s. 6d. a year, or 1s. a month, may borrow books included in this list, and others that will be added from time to time, and obtain advice on nursery problems.

REMUNERATION at the rate of £150 guineas a year has been sanctioned by the London County Council to each of seven medical superintendents of fever hospitals of the Metropolitan Asylums Board, in respect of services rendered in connexion with consultative work on and diagnosis of small-pox since the death of Dr. Wanklyn, consultant on small-pox to the Council, about a year ago.

AN effort is being made to establish in Bournemouth a home for elderly nurses, and an appeal has been issued by Miss Beatrice Harraden. Miss B. Hyla Greves, daughter of a past-president of the Dorset and West Hants Branch of the British Medical Association, is the honorary secretary of the Elderly Nurses Permanent Home Fund, which is being brought into being to provide this home; contributions may be sent to the honorary treasurer, Mr. F. Cobley, c/o Westminster Bank, Southbourne.

AN attempt in Lübeck, Germany, to secure immunization against tuberculosis by administering B.C.G. vaccine to infants has been followed by a number of deaths, and by a larger number of cases of serious illness. During the past two months 246 infants—about half the number born in Lübeck in that period—had undergone the treatment, and a report from Berlin dated May 20th states that up to that time seventeen of the infants had died, and over twenty others were seriously ill. The authorities at Lübeck are of the opinion that no contamination of the cultures could have occurred either during their transit from Paris or in the course of their further development in Lübeck itself. Professor Lange is investigating the outbreak on behalf of the State Office of Health, and an inquiry is being made also by the public prosecutor's department. Those in charge of the investigations are considering careless or incorrect handling or administration and pollution of the cultures as possible causes of the infections. It is stated that the health authorities allowed midwives to apply the preparation without medical control.

A REPORT has been issued on the work carried out during 1929 in the pathological laboratories of the City of London Hospital for Diseases of the Heart and Lungs. Investigations devised to establish the existence or otherwise of a filterable bacillus were undertaken on behalf of the Medical Research Council, and in collaboration with Dr. R. E. Glover and Dr. A. Stanley Griffith, of the department of animal pathology, Cambridge; no evidence was obtained of the existence of such a filterable form. A study of the clinical and pathological characteristics of pulmonary asbestosis was conducted by Dr. W. Burton Wood and Dr. S. Roodhouse Gloyne. The report contains reprints of publications on these subjects.

THE issue of the *Medical Journal of Australia* for March 22nd contained an appreciative leading article on the late Dr. William Henry Armit, its editor from 1914 to 1930, and this was followed on April 5th by a full obituary notice with portrait.

A SPECIAL number of *Bruxelles-médical* has recently been published giving an illustrated account of the annual congress known as the Journées Médicales de Bruxelles, which was held last June at Brussels.

THE late Mr. A. H. Tubby, consulting surgeon to Westminster Hospital and the Evelina Hospital for Children, has left estate of the value of £98,108, with net personality £37,812. He bequeathed £800 to Westminster Hospital and £100 to the Alpine Club.

THE Minister of Health has appointed Mr. W. A. Ross, O.B.E., and Mr. J. C. Wrigley to be Assistant Secretaries of the Ministry of Health.

THE London County Council has appointed Dr. Clifford Ellingworth as medical superintendent of Queen's Hospital, Sidcup, at a remuneration of £1,000 a year, with house. Fifty-seven applications were received in response to the advertisement of the appointment.

DR. HENRY H. I. HITCHON has been appointed to the Commission of the Peace for the borough of Heywood, Lancs.

THE Marquess of Linlithgow has resigned the office of President of the British Social Hygiene Council, and Sir Basil Blackett has accepted the invitation of the Executive Committee to succeed him.

THE following appointments have recently been made in foreign medical faculties: Professor Franz Hamburger of Graz, in succession to the late Professor Pirquet in the chair of paediatrics in Vienna; Dr. Wilhelm Pfannenstiel of Münster, professor of hygiene at Marburg; Dr. Adolf Jarisch of Innsbruck, professor of pharmacology at Düsseldorf, in succession to Professor Henburer; Professor Verzar, director of the physiological institute of Debreczen, successor of Professor Broemser in the chair of physiology at Basle; Dr. Cestan, professor of neurology and psychiatry at Toulouse, professor of clinical medicine in the same faculty; and Dr. Jean Turckini, professor of hydrology at Montpellier.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9361, 9362, 9363,* and *9364* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medocrem Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62350 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

PNEUMATIC DRILLS AS A CAUSE OF DISEASE.

DR. JOHN MCMILLAN (Shotts, Scotland) writes: Is there any record of the use of pneumatic breakers or picks (such as are used in breaking up the concrete and asphalt pavements of the London streets) having a deleterious effect on the health of men who work with such tools?

DANISH TREATMENT OF ITCH.

DR. ALEXANDER CANNON (Hong-Kong) writes: In reply to the inquiry of Dr. Douglas Ross in the *Journal* of February 15th (p. 320), there are many ways in which the first stage of the preparation of the ointment can be made up, still keeping to the same formula. Remembering that the chief difficulty is in getting the sublimated sulphur into solution, this is often done by first taking half of the 50 per cent. KOH and, if necessary, passing H_2S until saturation occurs, and then adding the other half. Another method is to use twice the amount of 50 per cent. KOH; this is not essential, but it saves considerable time in making up this first ingredient. In actual practice it does not matter very much whether a clear yellow solution is obtained, but this is the ideal, and can be achieved by using the best sublimated sulphur and KOH. A good deal also depends upon the meticulous preparation in this first step, often the best part of a whole day being required to get the end-result. Mr. Shenton, of Messrs. A. S. Watson and Co., informs me that they have made the solution according to the formula without difficulty. Mr. Cable, the chief Government apothecary of Hong-Kong, assures me that more often than not the colour is an orange yellow, and sometimes reddish in certain lights; the results of treatment are the same, however, which is the main point. The technique used by Mr. Cable is to dissolve the KOH and, while the solution is still hot, to sift the sublimed sulphur through a 40 sieve, while one man *constantly* stirs. As soon as the surface is covered with the commercial sublimed sulphur, this is stirred until dissolved, no more being added till then. Before the whole quantity is dissolved, a tedious process, the mixture frequently thickens considerably; we let it stand in the pan overnight, and in the morning a thick crust has formed, with a deep yellow-orange clear solution below. This is filtered, and the next step is then taken. Marcussen of Copenhagen always obtains a clear yellow solution, but he frequently uses 2 kg. of 50 per cent. KOH. With regard to the statement of Dr. Douglas Ross, "gentle heat merely blackens the mixture," I am at a loss to explain. All that I can say is that if the heat is never more than gentle, we have failed to produce a mere blackening; therefore I feel that it would be wise to seek further advice, and I should be greatly obliged if Dr. Martindale, or some other well-known chemist, would favour us with an exposition of the whole facts, if merely from the academic point of view. One thing I do know, and that is: carefully carry out the instructions given and you cannot fail to meet with success in every case.

INCOME TAX.

Motor Car Transactions.

R W. F. W." bought a car in 1922 for £530, and has been allowed depreciation at the rate of 20 per cent. on the written-down value since the depreciation regulation came into force. In June, 1929, he sold the car for £35 and bought a new one for £235. What should he claim?

*** The depreciation allowance was extended to the assessment of professional profits for 1925-26 and the following years. Consequently "W. F. W." has presumably had the allowance for

the five years 1925-26 to 1929-30 inclusive. We calculate the aggregate amount so allowed to be £228. He should therefore claim as an expense of the year 1929 the amount of the obsolescence allowance—that is, £235–£35=£200, and for the year 1930-31 depreciation at 20 per cent. on £235—that is, £47.

"C. D. S." bought a car in 1925 for £250. Last October he sold it for £10 and bought a second-hand car for £70. What can he claim?

*** Only the actual out-of-pocket expense of replacing the car—namely, £70–£10=£60. The difference between that amount and the £250 original outlay represents the gradual loss of capital sunk in the original car. As we have often pointed out, the only safe course is to claim the "depreciation" allowance as soon as possible—that is, as soon as any year occurs in computing the profits of which the expense of renewal of a car has not arisen and been claimed as such.

Residence Abroad.

"MEMBER" left England on July 6th, 1928, relinquishing his house in September, 1928, and since then has been continually travelling abroad. During the past four months he has been in the Irish Free State, where he hopes to settle permanently. He has a considerable holding in British companies and, of course, pays income tax by deduction from the dividends. Has he any claim for 1929-30 on the ground of foreign residence?

*** If, when he left England—or, at least, as from September, 1928—he definitely intended to sever his residential connexion with this country, we are of opinion on the above facts that he could claim to be regarded as a foreign resident for 1929-30. But it is not clear that this would assist him. Foreign residents—whether British subjects or not—are liable to income tax in respect of income derived from this country. Unless, therefore, "Member" is being regarded by the authorities as liable in respect of earnings during his absence from the United Kingdom, or is in receipt of interest on holdings in 5 per cent. War Loan—with regard to which foreign residents have special relief from British income tax—we see no advantage accruing from his claim to non-residence in the United Kingdom during 1929-30. For 1930-31 the position is different, as he will presumably be held liable to Free State tax, and will need to make a claim to secure relief from double taxation on the same income.

Motor Car Renewals.

"C." explains that in dealing with the liability of the firm of which he is a member the individual partners have in the past claimed and have been allowed the cost of replacing their cars as professional expenses. "C." would like to claim depreciation so far as his car is concerned, but his partners are claiming renewal expenditure this year.

*** It is a settled principle that renewal expenditure and depreciation cannot be allowed for the same year. A partnership is assessable as a single entity for income tax purposes, and, in our opinion, "C." cannot claim depreciation for a year in which the firm's assessment has been reduced by the allowance of renewal expenditure for any of his partners.

Cash Receipts Basis.

"S. C." explains that his firm is assessed on the "cash basis." One partner is retiring, his share being purchased by the remaining partners. Will the cash which reaches the retiring partner after he has ceased to practise, as his share of practice debts, be assessable for income tax?

*** Undoubtedly *not* so far as the retiring partner is concerned; his professional income has ceased, and with it his liability to assessment for any period after retirement. Neither will those receipts be assessable on the firm if they discard the cash basis in favour of value of bookings for the period after the change. But if the remaining partners desire to adhere to the cash basis they must bring into the account the whole of the cash receipts, whether paid over to the retired partner or not; the retained cash receipts by themselves do not reflect the full gross earning capacity of the practice.

Depreciation on Electrical Equipment.

"G. E." explains that the local inspector of taxes has offered him a rate of 7½ per cent. only on the written-down value for *x*-ray and other electrical appliances. This is inadequate, and in effect will postpone the real relief until obsolescence allowance can be claimed when the machines are replaced. They are now about five years old. Cannot he claim to have the allowance on the original cost instead of the written-down value?

*** No; the value as written down by the appropriate rate to the commencement of the financial year for which the allowance is claimed is the basis which has judicial support. "G. E.'s" only prospect of further present relief is to induce the inspector to allow depreciation at a higher rate than 7½ per cent.; at 10 per cent. it would take so long to reduce the value of the equipment to a break-up value that that rate would seem to be at least low enough for the safety of the Revenue.

Cost of Professional Accommodation.

"J. C." states that the inspector of taxes agrees to allow him to deduct as a professional expense one-half of the cost of the combined residence and surgery, etc. He asks as to the inclusion of certain specified items of expense.

*** "Estimated rental value" of the premises: this amount is the figure on which income tax is payable under Schedule A, and will be shown on the collector's demand note or receipt. "Landlord's tax": this is not deductible. "Rates and water rate": yes, according to the total amount payable for the year for which the professional receipts are calculated. "Estimated average repairs": the correct amount to deduct is the whole of the expenditure on those portions of the premises which are used professionally; if that cannot be ascertained, take half the total repairs. In either case the amount is that expended for the year in question, not an average figure.

LETTERS, NOTES, ETC.

CHANGES AND CHANCES.

FLEET SURGEON W. E. HOME, R.N.(ret.), writes: Your mention of the death of Fleet Surgeon W. Redmond (at Vancouver, at the age of 90) recalls to me three of his experiences. The first illustrates the changes of fortune. Sixty years ago he served in a sailing brig, under a lieutenant who used to complain to Redmond that he must soon retire, as there was no chance of promotion in the navy. Luckily he delayed a little; the tide turned, and he finished up, thirty years later, an Admiral, with a G.C.B. and G.C.M.G. and a Colonial Governorship to his credit. Redmond himself on retirement practised in Eastern Canada, but as he had once to drive ten miles to a labour case, and on the way got off the road into a snowdrift (from which his horse and trap were only rescued by driving in a herd of cattle to make a path out), spent a night from home, and only got 5 dollars, he thought the rewards too meagre, and went west—in fact, on the first transcontinental train into Vancouver of the Canadian Pacific Railway. He once drove into a village where a quack was cracking up Indian root pills, or something unofficial. "Ah!" said the quack to the people, "I see over there a man of education. Sir" (addressing Redmond), "is not this true: *Populus vult decipi?*" And Redmond said, "It is true." "And, Sir, is this not also true: *Decipiatur?*" "Yes, that is true, too," said Redmond. "Now," said the quack, "you see this man of education agrees with me. Can you do better than take my advice?" In British Columbia, when I knew him, he lived in a shack near the naval hospital at Esquimalt, spent the summers in shooting and fishing and the winters in the south. He had much charm of manner and was always a welcome visitor to the hospitals near which he rested, whether in California or British Columbia, so his experience became wide and his advice was much valued.

SWELLING OF FEET AND ANKLES WITHOUT ALBUMINURIA OR GROSS ORGANIC DISEASE.

"M.D., C.M." writes: In view of the article on this subject by Dr. Osman in the *Journal* of April 26th (p. 780) and of Dr. Royds Jones's letter on May 17th (p. 928), I think my experience while on a voyage from Liverpool to Valparaiso in November and December, 1919, may be of general interest. After a few days at sea I noticed considerable swelling of my feet and legs up to the knees, with pitting on pressure; this alarmed me considerably, but on examining my urine I found no albumin present, and I was otherwise in the best of health. On looking about for a cause it occurred to me that the daily morning hot brine bath might be giving rise to the condition. At first I used to take these baths fairly hot, and since one is allowed very little fresh water to sponge down with afterwards, I did not bother about this. However, on noting the swelling I was then more careful not to take the sea baths too hot, and to sponge myself all over with fresh water afterwards; the swelling did not recur, although I continued the salt sea baths for the whole of the voyage, and also on the return voyage from Buenos Aires to Southampton in the following March. I was then 48 years old, and now, eleven years afterwards, I am in good health and have no signs of albuminuria. It is a well-known clinical fact that a salt-free diet helps in dropsy, even in cases of Bright's disease. Many of the public have great faith in the efficacy of hot salt baths for the feet and legs in all sorts of affections, such as sore feet and rheumatism. Further investigation into the habits of people who suffer from this kind of oedema is indicated, whether they indulge in salt freely with their food, and whether they are given to bathing their limbs with hot sea-water.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 46, 47, 48, 49, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 235.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

467. The Heart Sounds in Mitral Stenosis.

J. J. MOZER and P. DUCHOSAL (*Arch. des Mal. du Cœur*, February, 1930, p. 74) has employed the electrophono-cardiograph to analyse the cardiac rhythm in mitral stenosis. By means of this instrument an electro-cardiogram is taken simultaneously with an electrical record of the sounds heard at the apex. The presystolic murmur was well shown, but never in the presence of auricular fibrillation or flutter. It was sometimes, though not usually, crescendo, the apparent frequency of this effect on auscultation being due to its being followed by the abrupt first sound. Reduplication of the first sound could readily be distinguished from a short presystolic murmur in the tracings. A diminuendo diastolic rumble following the reduplicated second sound generally faded away, but might be abruptly cut short by the succeeding first sound if diastole was short. The amplitude of the oscillations produced by the first heart sound was greater than that of the second. No sound is ordinarily heard during systole in pure mitral stenosis, but some of the tracings showed vibrations during this period; these were inaudible, since the frequency was only 25 to 30 each second. The elements of the reduplicated second sound were found to have a fairly constant time interval which was uninfluenced by respiration, the first element corresponding to the normal second sound, the second element falling in diastole. Reduplication never occurred if aortic incompetence coexisted, and from their findings the authors conclude that it is due to vibrations set up at the constricted mitral orifice by the transmitted shock of closure of aortic valves. Electrophono-cardiographic evidence is not in accord with the view that reduplication is due to relative alterations in tension in the pulmonary and systemic circuits.

468. Late Sequels of Poison Gases.

A. JACQUELIN and Mlle F. KONÉCHOWSKY (*Paris Méd.*, February 15th, 1930, p. 159) discuss the chronic non-tuberculous broncho-pulmonary lesions which persist after gas poisoning during the war. Of 200 unselected patients discharged with pension, 72 had inhaled either asphyxiating or vesicant gases in the years 1916–18. Of these, 83 per cent. were non-tuberculous, while 17 per cent. had pulmonary tuberculosis. The majority of the former class presented symptoms of pulmonary fibrosis, emphysema, and bronchitis, causing cough, dyspnœa, expectoration, and occasionally haemoptysis. Among these non-tuberculous cases 44 per cent. had emphysema, with or without pulmonary fibrosis. Chronic bronchitis with moderate emphysema was present in 19 per cent. Several patients had bronchiectasis with (ultimately) pulmonary abscess or gangrene. Paroxysmal dyspnœa, which became asthmatic in some cases, occurred in 11 per cent. Repeated attacks of haemoptysis were reported by 6 per cent. of the patients, while 3 per cent. of these had mediastinal adenopathy or mediastinitis, frequently simulating syphilitic lesions. The authors conclude that, apart from tuberculosis, two groups of lesions can be differentiated; the first, which is not entirely or necessarily due to poison gas, consists of patchy apical fibrosis, emphysema, chronic bronchitis, and may be due to other causes, such as the inhalation of irritating dust, excessive smoking, or alcoholism. The second group of lesions is produced definitely by gas poisoning in young, hitherto healthy subjects. These lesions comprise severe deforming pulmonary fibrosis, with definite basal emphysema; severe chronic purulent bronchitis, bronchiectasis, and pulmonary abscess; paroxysmal intractable dyspnœa, frequently amounting to true asthma.

469. Varicella Gangrenosa due to B. diphtheriae.

J. ZAHORSKY (*Journ. Amer. Med. Assoc.*, February 15th, 1930, p. 484) records the case of a boy, aged 7, who developed varicella, one of the lesions of which became gangrenous on the right leg. The nose and throat were normal. Considerable weakness of the left arm and leg was present. The heart showed a gallop rhythm, the liver was enlarged, and the urine contained albumin. Since these symptoms suggested diphtheria, a culture of the gangrenous lesions was taken and showed the presence of virulent diphtheria bacilli; 15,000 units of antitoxin were injected, but death, preceded by a high temperature and convulsions, took place. There was no autopsy. A fatal case of gangrenous varicella in which virulent *B. diphtheriae* was isolated from the nose during life was recently reported by Joe. In the present case, however, there was no faucial or nasal diphtheria present in the patient or in any member of the family.

470. Psittacosis.

C. KRUMWIEDE, MARY MCGRATH, and C. OLDENBUSCH (*Science*, March 7th, 1930, p. 262) recently investigated the etiology of psittacosis from material obtained from a series of cases, but in no instance was there any evidence of infection from *B. psittacosis*. A sick parrot in a family with two ill adults furnished the only case where material from both sources could be studied. On the death of the parrot an emulsion of its organs when fed and injected into another parrot gave rise to the same symptoms, and inoculation of another parrot with the emulsified organs of the first, filtered through a Berkefeld filter, produced the same picture, and materials from this latter parrot had the same result. Upon feeding a parrot with sputum and blood from one of the adult cases a disease resembling that of the parrot which had presumably been the source of infection resulted. The filtered organs of the inoculated parrot acted similarly upon another parrot, filtered material from which again caused fatal disease in a third parrot. The authors conclude that the primary cause of the disease was the filterable virus obtained from the original parrot and from the human sputum and blood; this virus killed mice, though its virulence for them did not appear to be very great, as a few survived. Emulsion of the organs of a fatal human case was also fatal for a parrot, but the results of filtration experiments are not yet completed. The authors conclude that a filterable virus is definitely indicated as the causative factor.

Surgery.

471. Surgical Treatment of Typhoid Carriers.

B. BERGGLES (*Wien. Arch. f. inn. Med.*, November, 1929, p. 285), who records five illustrative cases in patients aged from 20 to 47, three of whom were men and two women, emphasizes the epidemiological significance of two forms of late complications in enteric fever—namely, cholecystitis and osteitis—since patients with such complications are liable to become chronic carriers. Whereas no undoubted success resulted from the medical treatment of carriers with cholecystitis, 73 per cent. of those in whom cholecystectomy was performed could be regarded as cured. He concludes, therefore, that until the possibility of disinfecting the gall-bladder and bile ducts has been experimentally proved, treatment with this object should not be recommended. The clinical course of typhoid osteitis resembles that of osteitis due to the ordinary pyogenic organisms. Bacteriological investigations of the pus in every case of this kind are therefore necessary for the detection of carriers, and the treatment in such cases can only be surgical.

472. Shoulder Dislocations.

E. RIXFORD (*Amer. Journ. of Surg.*, February, 1930, p. 268) accounts for the fact that half of all dislocations occur at the shoulder by this joint possessing greater mobility than stability owing to the construction and roominess of the capsule, and by the small size of the glenoid cup, which covers only one-third of the cartilaginous surface of the head of the humerus. More than 90 per cent. of shoulder dislocations are primary subglenoid displacements in front of the triceps tendon, and are four times more frequent in men than in women. Dislocation may be due to a blow on the top of the shoulder, or as the result of leverage, the abduction of the shoulder being forced beyond the normal limit. Recognition

. . . . . .

the shoulder, Dugas's sign in anterior dislocation, positive palpation of the head of the humerus in its abnormal position, and *x*-ray examination, which shows the exact position of the head and reveals any complicating fracture. Dislocations of the shoulder are easily reduced without an anæsthetic if treated at once, but the difficulty of reduction increases with time; the cutting of the subscapularis muscle sometimes makes reduction more simple. The oldest and most satisfactory method is lateral traction when muscular relaxation has been secured. Old, unreduced dislocations must be treated according to each individual case: some are better left alone; others can be reduced after the contracted soft parts have been cut; while in other cases little but the resection of the head of the humerus can be done. Habitual dislocation may be treated by suturing the capsule through

an axillary incision or by shortening or re-attaching the supraspinatus. After reduction of the dislocation the arm should be bound to the side for two or three weeks to aid the healing of the wound in the capsule, after which time movement may be increased gradually.

473. Coxa Vara.

A. TREVES (*Bull. et Mém. Soc. de Chir.*, 1930, Tome xxii, Nos. 2 and 3, p. 67) considers that the percentage of cases suffering from coxa vara which belong to the adiposo-genital class has been greatly exaggerated, and that there are many cases which are independent of this diathesis. Cases are quoted as examples of the two principal types of coxa vara—namely, (1) that occurring in adolescents, which frequently coincides with puberty, and is often unilateral and analogous to genu valgum and tarsalgia; and (2) the progressive bilateral coxa vara which follows slight injury to a diseased hip, and gives the appearance of a slipped epiphysis, or of a fracture of the neck of the femur. The treatment in young children whose bones are still soft should consist in restoration at a single sitting, followed by the application of Whitman plaster in abduction and slight internal rotation. For adolescents the best results are obtained by successive plasters applied monthly. In cases where the neck of the femur is soft, rest should be recommended. Plasters must be kept on for at least three or four months. In cases where the coxa vara is established, or the bones are recalcified, subtrochanteric osteotomy is the treatment which gives the best results.

474. Cystitis Secondary to Kidney Disease.

V. VINTICI and N. N. CONSTANTINESCO (*Journ. d'Urol.*, February, 1930, p. 113) define cystitis as renal when it is due to a primary lesion of the kidney, such as pyelonephritis, calculus, or hydronephrosis, and not to infection with *B. coli* or pyogenic organisms. It occurs more frequently in women than in men. The bladder is more susceptible to infection from the organs above it than from below, as in the latter case the infection is usually confined to the bladder, while in cases of kidney infection there is almost invariably a reaction in the bladder as well. The bladder may react to kidney disease reflexly without any evidence of disease of the bladder, the inferior mesenteric ganglion referring the stimuli from the kidney to the bladder. Diagnosis is difficult when the patient complains of bladder trouble without any evidence of kidney disease, and in this case diagnosis as to the cause and nature of the lesion must be made by means of a microscopical examination of the urine, a cystoscopy followed by ureteral catheterization, or by pyelography. When the cystitis is accompanied by pyuria, frequency of micturition, and pain, diagnosis is simple. Prognosis depends on the response of the kidney trouble to treatment, since after the lesion has been dealt with the bladder quickly becomes normal; in cases where the bladder infection is bacillary in origin months or even years may elapse before a cure is effected. Treatment depends on the primary lesion, and may be nephrectomy, nephropexy, or nephrolithotomy, according to the individual case. Local treatment for the cystitis is unnecessary, as the trouble subsides immediately the causative factor has been removed, but it may possibly hasten convalescence. A principle which may well be followed is that a cystitis which persists or recurs, or which does not answer to simple treatment, must be suspected of being due to a pathological lesion of the kidney.

Therapeutics.

475. Pyretotherapy in Paralytic Dementia.

THE means employed in pyretotherapy, or the artificial induction of pyrexia, as a treatment of the psychoses may be divided into two classes: chemical, by hypodermic injections of sodium nucleinate or of various proteins; and infective, by the introduction of living organisms, especially the parasite of malaria and *Spirochaeta recurrentis duttoni*. The application of pyretotherapy to paralytic dementia is largely empirical, and few attempts have been made to explain the way in which the effects are brought about. H. W. EDDISON (*Journ. Mental Sci.*, January, 1930, p. 66) has endeavoured to do this by a study of the part played by the reticulo-endothelial system in the genesis and control of pyrexia, of the changes in the haematopoietic tissues in paralytic dementia, and of the effect of pyretotherapy upon the reticulo-endothelial system and its relation to the changes found in the blood-forming tissues in this disease. The study was based on a systematic observation for four years of 67 cases of untreated paralytic dementia and 21 of non-paretic syphilis, and involved 1,000 histological examinations; 500 blood examinations were made in 28 cases of paralytic dementia treated with relapsing fever, and in 4 treated by injections of foreign protein. In this series of cases changes were found in the bone marrow and blood in paralytic dementia, which showed that the leucopoietic functions were impaired and that the leucocyte reserve was diminished. In untreated cases there was a definite leucopenia. When leucocytosis was stimulated the intensity of the neutrophilic reaction varied inversely with the stage to which the paralytic dementia had advanced. Under the same conditions the Schilling index rose in direct proportion to the stage of the disease; the rise was most marked in those cases in which the decline was accelerated by pyretotherapy, and least marked in those which were benefited. The better the condition of the patient after treatment, the nearer did the differential leucocyte count and Schilling index approach the normal, and the converse was equally true. These changes are referable to affection of the reticulo-endothelial system, and therefore the involvement of this system by the syphilitic virus apparently constitutes one of the factors which determine whether a given syphilitic subject will develop paralytic dementia. In general, pyrexia is associated with a leucocytic reaction, and pyretotherapy stimulates the resistive function of the reticulo-endothelial system. Eddison considers that malarial therapy should be reserved for those cases in which a satisfactory leucocytic reaction has been obtained in a preliminary test with a mild leucogenic agent; owing to the importance of the reticulo-endothelial disturbance, patients who have benefited from malarial therapy should reside for a time at a high altitude in order to stimulate erythropoiesis and benefit leucopoiesis. Prophylactic malarial treatment should be advised for all syphilitic patients in whom few, if any, secondary or tertiary symptoms have been noted.

476. Vaccine Therapy in Chronic Ulcerative Colitis.

IN 1925 Bargen of the Mayo Clinic reported the isolation of a Gram-positive diplococcus from the depth of the ulcers in 90 per cent. of cases of chronic ulcerative colitis. After confirmatory animal experiments, vaccines and bacterial filtrates were prepared, and subcutaneous injections of these brought about clinical and pathological improvement in 80 per cent. of his cases. During the past two years W. Z. FRADKIN and I. GRAY (*Journ. Amer. Med. Assoc.*, March 22nd, 1930, p. 849) have had under their care fifteen patients with a definite history, symptoms, and proctoscopic evidence of chronic ulcerative proctitis; in three the Bargen diplococcus could not be detected in spite of repeated bacteriological trials, but in the remaining twelve the organism was found after the first, second, or third sigmoidoscopic examination. An autogenous vaccine prepared from this micro-organism was administered subcutaneously to these twelve patients three times a week for eight weeks; after eight injections improvement was noted in ten patients, and after eight weeks the patients reported that they felt better than at any time during their illness. In two cases vaccine therapy had to be continued for four months before cure was established. Only two patients failed to respond to the treatment. All the patients treated were given a diet of a high calorie value and rich in vitamins. The authors believe that the improvement noted in these cases was due to the vaccine treatment, and emphasize the need for repeated sigmoidoscopic examinations if the organism is not isolated at the first attempt. Improvement is noted more often and sooner, and is more lasting, when the vaccine therapy is supported by rest, fresh air, small blood transfusions, with high calorie and high vitamin diets, and the eradication of all possible foci of infection.

477. Serum Treatment of Adder Bite.

W. MENE (*Münch. med. Woch.*, February 21st, 1930, p. 307) has tested the toxicity of adder poison by the neutralizing action of antivenene serum E.R. of the Pasteur Institute, Paris. Increasing doses of dried adder poison dissolved in physiological saline solution were mixed *in vitro* with the same amount of E.R. serum, and after standing for an hour at 37° C. were injected intravenously into mice. Two samples of adder poison were tested. In one set it was found that the lethal dose of adder poison for a mouse was neutralized by a dose of 0.025 c.cm. of serum E.R. In the other set a dose of 0.0625 c.cm. of the same serum neutralized one and one-third times the lethal dose for the mouse for the sample of mixed adder poison. Whereas a mouse died within two hours after receiving the poison, another mouse was rescued by a dose given seventy minutes after the injection of the poison. The research confirms the findings of previous observers that E.R. serum is a powerful specific for the treatment of adder bite.

478. Adult Pooled Serum in Prophylaxis of Measles.

A. E. SIEGEL and H. ERMANN (*Amer. Journ. Med. Sci.*, February, 1930, p. 192), during an epidemic of measles among the school children of Philadelphia, injected the pooled Wassermann-negative serum of the children's parents in 5 c.cm. doses into fifty-five susceptible children without the development of a single case of measles even in an attenuated form.

Ophthalmology.

479. Radon in Chorioidal Sarcoma.

R. FOSTER MOORE (*Brit. Journ. of Ophthalmol.*, April, 1930, p. 145) reports a case of melanotic sarcoma of the choroid which was treated by means of radon seeds inserted intraocularly; twelve months have now elapsed since treatment was instituted. The reason for employing this method instead of removing the eye was that the right was an old blind eye, and the patient refused to have the left, the only seeing eye, removed. The patient, a man aged 65, had suffered from chronic blepharitis for several years. The right eye was convergent, and was the subject of a large dense leucoma adherens; with it he could just see hand movements. A large, very dark globular mass was seen in the lower part of the globe, and the ophthalmoscope showed that it invaded the dilated pupillary aperture. The vitreous was muddy, but there were no keratic precipitates and no evidence of iritis. The acuity was 6/60 and the visual field was reduced. The tumour was completely opaque to transillumination; the lower part of the iris was pushed a little forward; the tension was normal. Under general anaesthesia the conjunctiva was incised and a flap made which was dissected cleanly off the sclerotic. The knife was then pushed straight into the globe with a slight backward slope. The seed, of 1 millicurie strength with 0.5 mm. platinum filter, was inserted straight into the growth along the knife track. To the seed was attached a piece of black silk to facilitate future localization. The conjunctival flap was then replaced in position. After fourteen days the seed was removed under general anaesthesia. Apart from recurring pain, probably due to iritis, no important change was noticed. After about three months, as the growth was still easily visible, another seed of the greater strength of 5 millicuries with 0.5 mm. platinum filter was inserted at the same spot in the same way as previously. This seed was removed ten days later. At the present date, except for the blepharitis, the eye has given no trouble or pain. The growth has so regressed that it can only be seen with difficulty by looking well down behind the iris. Moore considers that an intraocular melanotic sarcoma can be made to shrink greatly, and perhaps to disappear, by this treatment, and that the danger of dissemination is no greater and no less than in removal of the eye. Without being dogmatic, he suggests that this method might be employed in cases of accessible intraocular sarcoma where the growth has not yet seriously spoiled the eye, and in the rare cases where the growth occurs in an only eye or in one which is the only useful eye.

480. Iridotasis for Primary and Secondary Glaucoma.

G. H. BELL (*Arch. of Ophthalmol.*, February, 1930, p. 194) reports 40 cases of glaucoma, in which iridotasis, an operation first suggested by Borthen in 1911, was undertaken; the results in 35 of these cases were good, but were poor in the remainder. Bell suggests that before operation is considered patients with chronic types of primary glaucoma, and also secondary glaucoma, should be first examined carefully for septic foci and receive appropriate treatment. Syphilis and other diseases should be excluded, and the patients be kept on a lactose and *acidophilus* diet. More than fifty patients thus treated have not so far come to operation owing to reduction in the ocular tension following treatment. The technique of iridotasis includes the drawing of the iris through a small incision in the anterior chamber, so that when the iris is withdrawn the pigmented epithelial layer is exposed and turned up opposite the anterior lip of the wound. Bell considers that the Reese iridectomy is the operation of choice in the acute inflammatory types of glaucoma. In the chronic types iridotasis is preferred, as there is a minimum injury to the eye and the iris is but little damaged. The operation is particularly indicated in patients with high blood pressure, or in whom the vessels are so fragile that a cutting operation might produce a haemorrhage of large proportions. It is a valuable operation in haemorrhagic glaucoma, and in cases in which the La Grange operation, the Elliot trephine, or an iridectomy has been unsuccessful. Iridotasis is the operation of choice in secondary glaucoma following anterior uveitis, and in that following extraction of the cataract; it may also be of advantage in buphthalmos. The only contraindication to the operation is a developing cataract complicating the glaucoma, when iridectomy is preferable. Late infections can be prevented by using a zinc sulphate solution (2 grains of zinc to 1 ounce of boric acid solution) in the eye night and morning; and this should be continued for a long time. While pleased with the results obtained by iridotasis, Bell considers that the prognosis in operations for glaucoma is unfavourable throughout, since patients usually seek treatment too late in the disease.

481. Operative Treatment of Retinal Detachment.

ACCORDING to J. GONIN (*Bruxelles-Méd.*, March 23rd, 1930, p. 564) the majority of the causes of blindness, such as ocular variola, gonorrhoea, cataract, and glaucoma, have been treated with increasing success, and only detachment of the retina has remained as apparently incurable. This affection is relatively frequent, more so than glaucoma, and more to be dreaded, since it often attacks eyes previously sound, with the exception of a certain degree of myopia. It spares no class of society, and, if more frequent in myopics and on the approach of old age, it occurs also in young and healthy subjects. Its pathogenesis is unknown. The first hypothesis that the elongation of the eye in myopia was a cause has been abandoned. A theory still held is that detachment of the retina is due to the raising of this membrane by an exudation of the choroid. Leber, having observed in cases of sudden detachment a tear in the retina, has concluded that the vitreous liquid escapes into the retroretinal space through this opening, and that the raising is not caused by a newly formed exudate, but by a simple change of situation of the liquid normally contained in the ocular cavity; this theory has been confirmed by clinical observations. Gonin states that these retinal tears are usually in the shape of a crescent or elongated horseshoe, and that their formation results from abnormal adhesions between the retina and the vitreous body, which can exist for a long time without ill effects. Treatment, to be successful, must be directed to the closing of these tears. Gonin performs a thermo-cauterization with the point of a Paquelin cautery across the sclerotic on a spot corresponding to the tear; this fixes the edges in a cicatrix common to the retina, the choroid, and the scleral shell. This treatment is well tolerated, and the results in many cases have surpassed expectations, complete cure being obtained in fifteen days. The great essential in the operation is the localization of the tear, and this is the only difficulty. In cases of longer duration than two or three weeks the chances of success are diminished, since the tears are more difficult to recognize, the retina is reapplied with greater difficulty, and the functional restoration is imperfect. Therefore, as early a diagnosis as possible should be made, and the operation be performed at once. Palliative treatment is strongly deprecated.

Obstetrics and Gynaecology.

482. Association of Menstruation and Ovulation.

E. NOVAK (*Journ. Amer. Med. Assoc.*, March 22nd, 1930, p. 853) discusses recent advances in the physiology of menstruation under the following four heads: the occurrence of menstruation without ovulation; the underlying cause of menstruation; the duality of the ovarian secretions; and the role of the anterior pituitary in the sex cycle. The sequence of events in the menstrual cycle is first briefly reviewed. Novak maintains that radical readjustments must be made in the physiological conception of menstruation. In the lower animals the sex cycle can occur independently of ovulation. Menstruation without preceding ovulation is not the rule in women, but it occurs at times, though the associated endometrial cycle would naturally be different in such cases. Even if preceding ovulation is the rule, it is not certain that the two are related in the nature of cause and effect. The doctrine of the "primacy of the ovum" in the regulation of menstrual periodicity must be abandoned in the light of recent evidence. No constituent of the ovarian structure is more important than any other in this respect, and there is evidence that the pituitary may, by the probable periodicity of its own function, be the regulator of the menstrual rhythm. The dual nature of the ovarian secretion has been definitely established, especially by the recent demonstration by Corner of an active corpus luteum extract, with properties in some respects antagonistic, in others supplementary, to those of the already well-recognized ovarian follicle hormone. The latter cannot now be regarded as the only female sex hormone, and the anterior pituitary secretion appears to play an even more fundamental part in sex physiology. Since the characteristic secretion of the corpus luteum has very different properties from those of the follicle and the placenta, the term "gestational gland" to include these three structures is incorrect. Novak holds that the most important and practical recent contribution to sex physiology is the discovery that the anterior portion of the pituitary gland supplies the motor energy of the ovary. Though the isolation of the follicle hormone has as yet yielded practically no therapeutic results, the discovery of the underlying role of the anterior pituitary secretion may be more productive of results in the treatment of disorders of the sex cycle.

483. Tubal Permeability in Sterility.

M. FRANCILLON-LOBRE and J. DALSACE (*Le Scalpel*, January 18th, 1930, p. 57) report a series of 222 unselected cases of women who complained of sterility, the condition being primary in 155 and secondary in 66. Lipiodol examinations were made in 208 cases, and 40 utero-tubal insufflations were given. The authors state that to obviate the chance of starting an ascending infection the patients should be selected, and only examined between the fifth and the twelfth day after menstruation. Careful preparation of the patient is necessary, and also constant measurement of the pressure of the lipiodol injection; rest and post-operative care should follow each investigation, which should never be considered as an out-patient procedure. Nearly all the women examined had previously undergone various therapeutic measures and in some there had been surgical intervention. In 17 cases an injection of lipiodol was given several months after an insufflation and in 10 cases the previous results were confirmed, but in the remainder impermeability to oxygen was associated with permeability to lipiodol; in two of these cases pregnancy followed some time after the lipiodol exploration. The authors add that another advantage of the use of lipiodol is the discovery of uterine or tubal lesions which may escape observation in insufflation. The physio-pathology of the uterus and tubes can only be studied by the help of radiograms in series, which may reveal causes of sterility other than simple obliteration of the tubes—namely, kinetic spasms, elongations, malformations, and latero-flexions. Great difficulty was experienced in obtaining records of the subsequent history of the 222 women examined, but the authors discovered that 19 (8.5 per cent.) subsequently became pregnant. In these 19 cases a total of 23 pregnancies was reported, 15 living infants being born; there were 7 miscarriages and one extrauterine gestation. As a result of the diagnosis made after lipiodol insufflations 19 women underwent laparotomy, and many lesions were discovered and remedied which were undetectable by vaginal examination.

484. The Sedimentation Test in Pregnancy.

P. B. BLAND, L. GOLDSTEIN, and A. FIRST (*Surg., Gynecol. and Obstet.*, February, 1930, p. 429) studied the sedimentation of the erythrocytes in pregnancy especially in its relation to anaemia, the existence of a blood deficiency in pregnancy having been previously described. Tests performed upon 540 healthy women in different months of gestation were analysed. It was found that 536 (99 per cent.) had an increased sedimentation index, while in six women as early as the second month of pregnancy three showed an increased index, and of 453 examined in the sixth month or later 75 per cent. showed a marked acceleration of sedimentation. The authors remark that anaemia appears to be a factor in determining the rate of settling of the erythrocytes in pregnancy, as it is in other pathological conditions. The sedimentation value is an index of the coagulating property of the blood, a prolonged or delayed sedimentation indicating a delay in coagulation at the time of the expulsion of the foetus and placenta, with the possibility of post-partum haemorrhage. A patient with a severe grade of anaemia combined with slow sedimentation would be very prone to excessive haemorrhage during or after labour. The sedimentation rates occurring during pregnancy were maintained during the first ten days following delivery. The authors conclude that the sedimentation of the erythrocytes is much more rapid in the pregnant than in the non-pregnant state; the acceleration is primarily due to the increased fibrinogen content of the plasma, and secondarily to the physiological anaemia and leucocytosis present in pregnancy.

Pathology.

485. A Proteolytic Uterine Ferment.

THOUGH most secretions containing digestive ferments are produced by endodermal tissues, tryptic ferments have been demonstrated in such mesodermal organs as the kidneys, liver, and spleen. P. CAFFIER (*Münch. med. Woch.*, March 7th, 1930, p. 389), following Frankl, Halban, and Aschner, has therefore examined the secretion of the human uterus at different stages in the menstrual cycle, and states that he has obtained definite evidence of the presence of a proteolytic ferment which appears to be formed in the glandular epithelium of the endometrium, the largest amount being found when the endometrial glands are proliferating most actively. The activity of this ferment was found to be destroyed by heating to 80° C. or by the addition of formalin, but after complete drying at 56° an active suspension could be prepared from the same material three months later. Since this ferment is present in maximum amount in the free secretion of the uterus in the pre-menstrual phase, Caffier considers it likely that it takes an active part in [illegible] integration of the endometrium associated [illegible]; by the destruction of gland cells further ferment is liberated, and the menstrual discharge is thus largely an autolytic product. The uterine ferment possibly destroys unfertilized ova and spermatozoa, and may play a part in preparing the endometrium for the implantation of the fertilized ovum.

486. Spontaneous Tuberculosis in the Guinea-pig.

THE liability of the guinea-pig to contract tuberculosis spontaneously when living in the same room as tuberculous animals was noted by Koch, and has been confirmed by many other workers on tuberculosis, including Reisman and Baylis (see *Epitome*, February 15th, para. 177). As the result of experimental work at Cambridge, A. S. GRIFFITH (*Journ. Path. and Bact.*, January, 1930, p. 153) has found that this disease does appear spontaneously in guinea-pigs, but rarely. Casual tuberculosis acquired by these animals is generally of respiratory origin, and is often remarkable for the enormous enlargement of the tracheo-bronchial glands, which contain cheesy caseous substance and have greatly thickened capsules. Spontaneous tuberculosis of alimentary origin occurs chiefly in young animals which have been suckled by mothers with tuberculous abdominal ulcers. The type of infecting tubercle bacillus was ascertained by several observers to be either bovine or human, the former predominating. Of seven strains examined by Griffith, six were bovine and one was human. Recently he has discovered two further cases of spontaneous tuberculosis in guinea-pigs, cultures from which proved to be of the avian type, a type to which the guinea-pig is highly resistant. The cultures exhibited the moist slimy character of the typical avian bacillus and showed many branched forms. The condition differed from that caused by mammalian bacilli in that the lesions were yellow and purulent with little surrounding fibrotic change, and the tubercle bacilli were more abundant in the pus. The author thinks, therefore, that it may be taken as proved that spontaneous tuberculosis of the bovine, human, or avian type does occur in guinea-pigs.

487. The Reticulocyte Response in Anaemia.

C. S. YANG and C. S. KEEFER (*Arch. Int. Med.*, March, 1930, p. 456), from observations in 53 cases of secondary anaemia, found that the response of the reticulocytes depended upon the severity and cause of the anaemia and upon the form of treatment, the counts ranging from 1 to 35 per cent. The most marked reaction occurred in the anaemias associated with hookworm infection, haemorrhage, dysentery, undernutrition, pregnancy, and malaria; usually, the lower the original count the higher did it rise during recovery. Poor nutrition seemed to play a considerable part, and treatment with liver and iron or cod-liver oil and a high calorie diet resulted in an increased percentage of reticulocytes, and an improvement in the anaemia. In many instances the results obtained by such treatment were as striking as those brought about in pernicious anaemia by the administration of liver or liver extract; it seems that feeding of liver is not specific only for pernicious anaemia, but that it has a beneficial effect in many secondary anaemias, and in many cases a combination of liver and iron was found to be more effective than either alone. From their own cases and from others previously reported secondary anaemia was often found to react in the same way to treatment with liver or liver and iron as does pernicious anaemia to liver or liver extract.

488. The Anaemia of Splenectomized Rats.

M. LEVI (*Lo Sperimentale*, March, 1930, p. xvi) removed the spleens of a number of rats which had been bred in Florence; two or three days later the animals showed symptoms of illness, and haemoglobinuria was found to be present. Anaemia developed, the red cells falling from 9,000,000 to 1,200,000 per c.mm.; there was a relative leucocytosis associated with the appearance in the blood of a large number of polymorphonuclear cells. The platelets likewise showed a marked increase, and the colour index varied from 1.1 to 1.25. Examination of the blood with brilliant cresyl blue revealed the presence of fairly large bodies in the red corpuscles, sometimes large enough to fill the entire cell, and exhibiting active Brownian motility. Stained by the Giemsa method, they appeared as granules and as straight or curved rods. Four to five days after splenectomy about 2 to 5 per cent. of the red cells were affected, but by the sixteenth day practically every cell was attacked. Preliminary experiments showed that a normal rat put into the same cage as a splenectomized rat developed the typical intracellular formations. The author is satisfied that splenectomy in rats in Italy has apparently the same effect as in other countries; he maintains an open mind as to the nature of the intracellular bodies, regarding their bacterial nature as not yet definitely proved.

The guide is human milk, the aim . . . a balanced milk-food

In infant feeding the natural standard is the milk of a normal, healthy mother.

This has been the guide in making Sunshine Glaxo. The cleanest possible fresh milk is used—and adjusted to the infant's needs. Lack of balance, indigestibility of curd and deficiency of Vitamin D, are in turn corrected; and thus the recognised objections to raw (and modified) cows' milk are overcome.

BACTERIOLOGICALLY-TESTED MILK OF SELECTED HERDS

Sunshine Glaxo is controlled by analyses at many points—from the bacteriological examination of the fresh milk to the tests for the standard amount of Vitamin D in the finished food.

FULLY HUMANISED MILK-FOOD WITH ADDED "OSTELIN" VITAMIN D . . .

"Ordinary milk sold throughout the greater part of the year contains almost no anti-rachitic vitamin."—THE LANCET, *Nov. 23rd, 1929* (p. 1090). Sunshine Glaxo therefore contains a standard amount of Vitamin D—with the aim of comparing as favourably as possible with human milk.

ADJUSTED FAT CONTENT—BALANCE OF ALL ELEMENTS

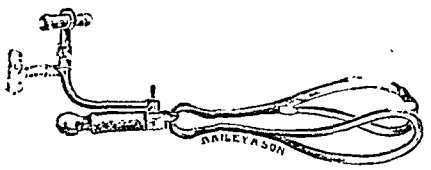
As it contains adequate Vitamin D from other sources, the fat content of Sunshine Glaxo is adjusted. Thereby, fat intolerance and similar digestive disturbances are avoided.

Sunshine Glaxo has a balance of all the food elements—even to the mineral content, including iron.

UNHARMED BY CLIMATIC OR WEATHER CONDITIONS

The Glaxo processes give many advantages to Sunshine Glaxo—such, for instance, as the light, flocculent, easily digestible curd. Forethought is extended to every detail of packing as well, so that, even in the Tropics, Sunshine Glaxo keeps perfectly.

All over the world, Sunshine Glaxo is the safe food to prescribe whenever it is impossible or inadvisable for the infant to be breast fed.



SUNSHINE GLAXO

The results of biochemical and bacteriological research carried out in the Glaxo Laboratories will willingly be communicated to all enquirers. The extensive library and other facilities available to the scientific staff are always at the disposal of practitioners on all matters of nutritional and dietetic research.

Some Unsolicited Appreciation

Dear Sirs,—I beg to thank you for the best stethoscope I ever used, and during the last forty years I have used a good many.
Yours faithfully, ——

Dear Sirs,—I find that most certainly the chest sounds are rendered clearer and more distinct by your "Phonophore" than by any Stethoscope I have used during over thirty years' work.—Yours faithfully, ——

Dear Sirs,—I find your "Phonophore" indispensable. Being more or less deaf, without it I should be compelled to relinquish practice. With it I can hold my own.
Yours faithfully, ——

Dear Sirs,—The "Phonophore" is extremely satisfactory and far superior to any stethoscope I have used.
Yours truly, ——

Makers of Superior Surgical Instruments and Appliances.

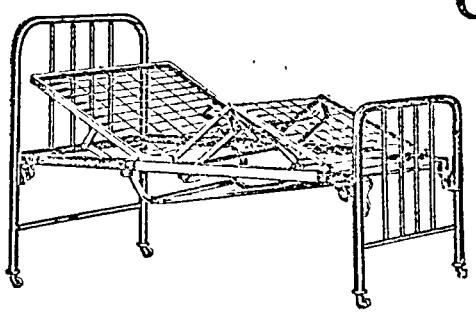
AUGUST
SEPTEMBER

With the advent of Spring, peoples' thoughts naturally turn towards Lighter clothing, yet patients thinking thus still retain the heavy winter appliance, not being aware that we manufacture suitable Belts of lighter texture.

The heavy Belt, when worn during warm weather, induces excessive perspiration, thereby shortening the life of the appliance.



Warmer days call for lighter clothes—therefore, are not lighter appliances in natural corollary?

Patients will eagerly welcome the added comfort and complete freedom of movement for outdoor exercises afforded by—

SALT'S Special Lightweight APPLIANCES.

SALT AND SON LTD.
7, CHERRY ST., BIRMINGHAM.

COPYRIGHT. ESTABLISHED 1793.

A turn of the crank adjusts the position.

Convalescence Comfort means—
fewer calls for nurse!

The folding spring of the Simmons Hospital Bed supports the body in any desirable position of repose. This dispels the necessity of constantly rearranging pillows, gives maximum comfort for patient, and more leisure for nurse. Furthermore, this hygienic bed is ideal for surgical positions.

METATARSALGIA

The intense discomfort and nervous strain caused by a partial or complete collapse of the arch of the foot brings this condition to the notice of the physicians.

The invention of the Korcet Shoe has made it possible to deal with each stage of the complaint adequately. This shoe is unique and contains built-in elements in its construction which gives complete support, a resilient spring, lateral supports, and a metatarsal pad on which the ball of the foot rests in comfort.

Note.
FIG. A.—Shows the way in which the foot is supported within the Korcet Shoe.
A booklet entitled "Foot Relief" on request.

FOR DEAFNESS

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

FREE HOME TESTS arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

How can Keith Bradbury Ltd. sell clothes at cash prices for £1 per month?

THE ANSWER

IN providing say our first 1,000 customers with clothes upon the subscription basis, naturally we would be obliged to sink a capital sum of something like £6,000; but after this we receive a monthly income of £1,000, which automatically meets the cost of running the business.

The interest on the capital invested at 5% amounts to £300, but when this is apportioned it does not represent a per suit cost of 2/6, and even this is offset by cash discounts since a regular income enables us to pay the manufacturers cash for their cloth.

Upon the old-fashioned 'alleged' cash basis of doing business, tailors give 3, 6 and sometimes 12 months' credit which results in considerable interest charges and dead capital, followed by bad debts.

These heavy overhead expenses are not incurred by Keith Bradbury Ltd. on their monthly basis of doing business, with the result that a FREE VALET SERVICE can be provided for the care of customers' clothes after purchase.

There is nothing undignified in accepting credit from your tailor, any more than there is in arranging terms with a Bank or Building Society—and it is certainly more convenient to pay your way out of income rather than to disturb capital.

Please come and see for yourself the low-priced West End clothing which Keith Bradbury Ltd. can offer by doing business on a monthly basis at terms of from £1 per month.

An interesting catalogue and full particulars of our credit facilities gladly sent on request.

LOUNGE SUITS, FORMAL WEAR, SPORTS SUITS from 5 gns. FLANNEL BLAZERS from 45/-, TROUSERS from 21/-. DINNER SUITS from 6 gns. FULL DRESS WEAR from 7 gns.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

1 HILL PLACE EDINBURGH

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, Russian baths, the prolonged immersion bath, Vichy Douche, Scotch [illegible] Plombières treatment, etc. There is an Operating Theatre, a Dental [illegible]oom, an Ultra-violet Apparatus, and a Department for Diathermy and [illegible]tment. It also contains Laboratories for biochemical, bacteriological, [illegible]

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.
Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and out-door recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.
FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—
Dr. F. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

ALCOHOLISM, DRUG HABIT, NEURASTHENIA, etc.
BAY MOUNT, PAIGNTON.

ESTABLISHED 1922. *'Phone*: PAIGNTON 5110.

A comfortable, private HOME, charmingly situated, overlooking Torbay, near Torquay. Main line, 3½ hours from Paddington. Both Ladies and Gentlemen admitted as voluntary patients. The treatment is the outcome of many years' experience, and besides removing all craving for drink or drugs, it has a tonic action on the system and the general health is improved. Alcohol and drugs reduced gradually, without suffering.

FUNCTIONAL NERVOUS DISEASES AND NEURASTHENIA are also treated with excellent results. Cases with insomnia, depression, etc., do especially well.

May 9th, 1930. Council.

Salop County Council.

MEDICAL INSPECTION OF SCHOOL CHILDREN AND MATERNITY AND CHILD WELFARE.

Applications are invited from registered Medical Practitioners (male) for the post of Assistant Medical Officer to work under these Schemes. Salary £600 per annum, rising by annual increments of £25 to a maximum of £700, with travelling and out-of-pocket expenses on a fixed scale.
The salary will be subject to a deduction of 5 per cent. for superannuation under the Local Government and Other Officers Superannuation Act, 1922, and the candidate selected will be required to pass a medical examination.
Candidates must possess a Diploma in Public Health, and experience in Refraction work will be considered an important additional qualification.
Applications should be received on or before Wednesday, June 11th, by the County Medical Officer of Health, College Hill House, Shrewsbury, from whom forms of application, conditions of appointment, list of duties, and any other information can be obtained.

City of Sheffield.

NETHER EDGE HOSPITAL.

Applications are invited from duly qualified Medical Women for the post of RESIDENT HOUSE PHYSICIAN in the above Hospital.
The appointment will be, in the first instance, for one year. Salary at the rate of £150 per annum.
Applications, stating age, qualifications, and experience, and accompanied by not more than three recent testimonials, should be sent at once to the Medical Superintendent, City General Hospitals, Fir Vale, Sheffield.

Cumberland County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from fully qualified Medical Men holding a Diploma in Public Health.
Salary commences at £600 per annum, rising by annual increments of £25 to £700, with travelling and subsistence allowance.
The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, terminable by two months' written notice on either side, and the person appointed will be required to devote the whole of his time to his duties under the supervision of the County Medical Officer of Health.
Forms of application may be obtained from the County Medical Officer, Citadel Chambers, Carlisle, on receipt of a stamped addressed foolscap envelope.
Applications, endorsed "Assistant Medical Officer," and accompanied by copies of three recent testimonials, must be received by the County Medical Officer of Health not later than Thursday, June 5th.
Canvassing is a disqualification.

C. W. ALLAN HODGSON,
County Offices, Clerk of the
Carlisle. County Council.
May 12th, 1930.

Oldbury Urban District Council.

ASSISTANT MEDICAL OFFICER.

The Council invite applications for the above appointment.
Applicants must be registered Medical Practitioners holding the Diploma of Public Health, and with experience in Ante-natal work, and preference will be given to those who have held a resident appointment at a Maternity Hospital with an ante-natal clinic.
The person appointed will act under the supervision of the Medical Officer of Health and School Medical Officer, and assist him in the general administration of the Health Department, including the School Medical and Maternity and Child Welfare services.
The person appointed must devote whole time to the duties of the appointment.
Salary £600 per annum, with £10 travelling expenses per annum.
Application forms, with further particulars of the appointment, may be obtained from the undersigned, and should be returned, together with copies of three recent testimonials, not later than June 12th, endorsed "Assistant Medical Officer."

ARTHUR CULWICK,
Council Offices, Clerk of the Council.
Oldbury.
May 16th, 1930.

County Borough of Ipswich.

Applications are invited for the post of ASSISTANT MEDICAL OFFICER to the IPSWICH SANATORIUM. Salary £350 per annum, with board, lodging, washing, etc., subject to deductions in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922. The appointment will be for one year in the first instance. Applicants must be bachelors and must be fully qualified and registered, and must not exceed 30 years of age. They must have held a resident post in a General Hospital and also in a Hospital for the treatment of diseases of the chest.
Applications, stating age, qualifications, experience, and accompanied by recent testimonials, should be sent to the undersigned forthwith.

W. F. SUTCLIFFE,
Ipswich Sanatorium. Medical Supt.

Applications, with copies of testimonials, should be addressed to the undersigned forthwith.
Board Room, JNO. W. BARNES, F.C.I.S.,
May 14th, 1930. Gen. Supt. & Sec.

Arbroath Infirmary.

Wanted, for Arbroath Infirmary, SENIOR RESIDENT MEDICAL OFFICER (male) for the period from the date of his acceptance of the appointment to January 14th, 1931, at a salary of £120 per annum.
The appointment affords excellent opportunity for surgical and other experience.
The House contains about 50 beds.
Applications, with two recent testimonials, addressed to the Chairman, Weekly Committee, Arbroath Infirmary, to be lodged by Tuesday, May 27th.

Antrim County Council.

CHIEF TUBERCULOSIS MEDICAL OFFICER wanted.

The County Council of the County of Antrim hereby give notice that they will at their meeting to be held in the County Courthouse, Belfast, on Tuesday, June 17th next, proceed to appoint a registered Medical Practitioner as Chief Tuberculosis Medical Officer for the County, at a salary of £750 per annum, with an annual allowance of £120 for travelling expenses. The person appointed must devote his whole time to the duties of the office and reside in the City of Belfast, his absence not to exceed 40 days. In addition to the ordinary duties of the office, the person appointed will require to attend all meetings of the Tuberculosis Committee and Insurance Committee and act as Medical Adviser to the latter Committee, and generally to perform such duties as may be assigned from time to time by the Council with the approval of the Ministry of Home Affairs.

Candidates must either—

(a) Have acted as Superintendent or Assistant Superintendent of a Sanatorium or Tuberculosis Dispensary for at least six months, or

(b) Have obtained a certificate of proficiency in the diagnosis and treatment of Tuberculosis, or

(c) Attended a six months course of instruction at any Institution that may be recognised by the Ministry of Home Affairs for Northern Ireland as an efficient school for giving such instruction, or

(d) with raise satisfy the Ministry that he possesses special knowledge of the diagnosis and treatment of Tuberculosis.

Preference will be given to candidates who have had at least three years' experience in Tuberculosis work and have obtained a Diploma in Public Health.

The appointment to be regarded as temporary pending the reform of the Local Government services, but the officer appointed will be considered eligible for promotion to the post of County Medical Officer of Health if and when the Public Scheme of Local Government Reorganization comes into operation, and in this connection the Council will take into consideration any experience of a general character which candidates possess.

The person appointed will also have to carry out the duties of the office of Medical Superintendent of the Sanatorium and such portion of the Tuberculosis Dispensary Work for which he is appointed Medical Officer by the Council.

Salary £600 per annum, and an additional £40 per annum.

Applications, stating qualifications and experience, accompanied by testimonials, must be received by the undersigned at the County Courthouse, Belfast, not later than June 7th next.

ALEXANDER MILLAR, Secretary.

County Courthouse, Belfast. May 14th 1930

Berkshire County Council.

ASSISTANT TUBERCULOSIS OFFICER AND GENERAL MEDICAL ASSISTANT

Applications are invited for the above combined appointment. Salary £600 per annum. The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922. Candidates must be qualified to hold an appointment as Tuberculosis Officer as required by the Local Government (Qualifications of Medical Officers) Regulations, 1930, and must also have a Diploma in Public Health. Forms of application and full particulars may be obtained from the Clerk of the County Council.

Applications, accompanied by three testimonials, must reach the undersigned on or before Saturday, May 31st.

H. J. C. NEOBARD, Clerk of the County Council.

Shire Hall, The Forbury, Reading.

May 16th 1930

City of Manchester.

RADIOLOGIST.

The Public Health Committee invite applications from registered Medical Practitioners for the appointment of Radiologist at the CRUMPSALL HOSPITAL, Crumpsall, Manchester, at a salary at the rate of £500 per annum.

The successful candidate will be required to give four half-day sessions per week at the Hospital, respond to emergency calls, provide his own locum for holiday duty, execute the Corporation Deed of Service, and to commence duty as soon as possible after appointment.

Applications, endorsed on the envelope "Radiologist, Crumpsall," accompanied by not less than three testimonials, must be forwarded to the undersigned not later than Monday, June 2nd.

F. E. WARBRECK HOWELL, Town Clerk.

Town Hall, Manchester. May 15th 1930.

City of Plymouth.

DEPUTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered Medical Men for the post of whole-time Deputy Medical Officer of Health to the City of Plymouth.

Applicants must possess a Diploma in Public Health or a qualification in State Medicine.

The salary will be at the rate of £750 per annum, rising by annual increments of £50 to £900 per annum, and the appointment will be terminable by three months' notice on either side.

The person appointed will be required to act for the Medical Officer of Health in his absence, and generally to help him in the Public Health work of the City, and in the various Sub-departments of the Public Health Department. He will act under the general supervision and direction of the Medical Officer of Health, and carry out any duties delegated to him from time to time.

Forms of application will not be provided. Candidates for this appointment should state their age and give an account of their professional qualifications and experience in all branches of Public Health work.

Canvassing will disqualify the applicant.

Applications must be received by the undersigned on or before Thursday, June 5th, and envelopes must be endorsed "Deputy Medical Officer of Health."

A. T. NANKIVELL, M.D., M.R.C.P., D.P.H., Medical Officer of Health, City and Port of Plymouth.

Town Hall, Stonehouse, Plymouth.

May 8th, 1930.

City of Plymouth.

RESIDENT MEDICAL SUPERINTENDENT.

Applications are invited from duly qualified and registered Medical Practitioners for the post of Resident Medical Superintendent of the Plymouth City Hospital.

The salary will be at the rate of £1,000 per year, with food, quarters, lighting, heating, and washing. No canvassing for this appointment is permitted, and any canvassing will disqualify the applicant. The appointment will be terminable by three months' notice on either side.

Applicants must be holders of the F.R.C.S., or the Degree of a Master of Surgery in a University of the United Kingdom. The appointment is whole-time, and private practice is not permitted. The person appointed will be an Assistant Medical Officer in the Public Health Department, and will be on the staff of the Medical Officer of Health, who is the General Medical Superintendent of the Corporation Hospitals.

Applications will be considered only on the forms of application which will be provided. A form of application, together with further details relating to the appointment, can be obtained from the undersigned, on the receipt by him of a request for this, accompanied by a stamped and addressed envelope. Forms of application, duly completed, together with copies of not more than three recent testimonials, must be returned to the undersigned not later than June 5th.

A. T. NANKIVELL, M.D., M.R.C.P., D.P.H., etc., Medical Officer of Health.

Town Hall, Stonehouse, Plymouth.

May 8th, 1930.

County Borough of Rotherham.

ASSISTANT MEDICAL OFFICER OF HEALTH

The Rotherham Corporation invite applications from duly qualified and registered Medical Practitioners for the position of Assistant Medical Officer of Health with principal duties relating to Venereal Diseases, and Maternity and Child Welfare. The Officer appointed will also act as Medical Officer to the Municipal Maternity Home. Preference will be given to candidates holding the Diploma of Public Health. Salary £500.

The gentleman appointed will be required to devote the whole of his time to the duties of the office and to reside in the Borough, and will not be allowed to engage in private practice, and all emoluments or fees which may be payable to or received by him will have to be paid to the Corporation.

The appointment will be subject (1) to the passing of a medical examination; (2) to the provisions of the Sanitary Officers Order, 1925; (3) to be subject to the Local Government and other Officers Superannuation Act, 1922, and (4) to termination by three months' previous notice.

A list of duties can be obtained from the Medical Officer of Health.

Canvassing, either directly or indirectly, is prohibited.

Applications, with copies of not more than three recent testimonials attached, to be sent to me, endorsed "Assistant Medical Officer of Health," not later than May 26th.

CHAS. L. DES FORGES, Town Clerk.

Municipal Offices, Rotherham.

May 7th, 1930.

County Borough of Newport.

ASSISTANT LADY MEDICAL OFFICER in the MEDICAL OFFICER OF HEALTH'S DEPT.

Applications are invited for the position of Lady Assistant Medical Officer of Health. Candidates must be duly qualified and registered Medical Practitioners; have had not less than three years' experience since graduation; special experience in Midwifery and Child Welfare work; and must hold a Diploma in Public Health.

Other qualifications being equal, preference will be given to one with experience in the Diagnosis and Treatment of V.D. among women and children, and U.V.R. Therapy.

The lady appointed will act under the direction of the Medical Officer of Health, and will devote her whole time to official duties, which will be to assist at the Maternity and Child Welfare Clinic and Centres to undertake Diagnosis and Treatment of V.D. among women and infants; U.V.R. Therapy; superintendence of practising midwives and of Health Visitors; and to carry out any other duties required by the Medical Officer of Health.

The salary will be £600 per annum. The appointment is subject to the Local Government and Other Officers Superannuation Act, 1922, and deductions from salary and the passing of a medical examination thereunder.

The appointment will be subject to two calendar months' notice on either side.

Applications should be made on forms to be obtained from the Medical Officer of Health, and must be accompanied by copies (not originals) of three recent testimonials. Envelopes, addressed to the Medical Officer of Health, and marked "Assistant Medical Officer," must be received not later than June 1st.

J. HOWARD-JONES, M.D., D.Sc. Medical Officer of Health.

APPOINTMENTS.—Contd.

City of Liverpool.

PUBLIC ASSISTANCE COMMITTEE.

RESIDENT ASSISTANT MEDICAL OFFICER (Male).

The Committee invite applications for the appointment of a Resident Assistant Medical Officer (male) at the MILL ROAD INFIRMARY, Liverpool, at a salary after the rate of £200 per annum, together with the usual residential allowances.

Candidates must be single, fully qualified, and registered.

The appointment will be for a period of one year in the first instance, subject to extension for a further period not exceeding twelve months, at the option of the Committee.

Applications, stating age, qualifications, etc., with copies of three testimonials, to be received by the undersigned not later than Tuesday, June 3rd.

WALTER MOON,
Town Clerk.

Public Assistance Offices,
Brougham Terrace, Liverpool.
May 20th, 1930.

General Infirmary, Salisbury.
(General Hospital—151 Beds.)

Two HOUSE SURGEONS (male) required to commence duty at the end of June and the beginning of July.

Candidates must be unmarried, fully qualified, and registered. Salary £150, with board, etc.

Applications, with copies of testimonials, to be sent to the House Governor and Secretary, from whom a copy of the rules may be obtained on application.

The Manor House Hospital,
Golders Green, London. (112 Beds.)

Applications are invited for the post of HOUSE SURGEON. Salary at the rate of £200 per annum, with board, residence, and laundry. Candidates (male and unmarried) must be fully qualified and registered. Applications, stating full particulars, should be addressed to the Secretary at the Hospital as soon as possible.

Resident Medical Officer required Salary at the rate of £150 per annum, with board, lodging, and laundry. Hospital contains 70 beds.

Applications to be sent to the Secretary, CHELMSFORD & ESSEX HOSPITAL, CHELMSFORD, by May 24th.

House Surgeon, male, wanted immediately for HUNTINGDON HOSPITAL. Salary £125 per annum and laundry. Testimonials, etc., to Dr. GROVE, County Hospital, Huntingdon.

The Royal Infirmary,
SUNDERLAND.

APPOINTMENT OF HONORARY PHYSICIAN.

The Board of Management invites applications for the appointment of an Honorary Physician. Candidates for the office shall be a Doctor in Medicine of some British or Irish University or a Fellow or Member of a Royal College of Physicians, and be registered according to the Medical Act.

The Hospital has 291 beds (including 29 pay beds) and the usual special departments. The person appointed will be required to practise as a Consulting Physician and not as a General Practitioner.

The Board of Management is prepared to guarantee the selected candidate, for a period of five years, an income from this and other public appointments, of £500 per annum.

Copy of rules may be obtained from the undersigned, by whom all applications, stating age, and giving full particulars of qualifications and experience, must be received by not later than June 28th.

Canvassing will be considered a disqualification, but candidates shall be at liberty to send to each member of the Board of Management copies of their applications and testimonials.

S. C. FRYERS,
House Governor and Secretary.

Rotherham County Borough.

RESIDENT ASSISTANT MEDICAL OFFICER.

The Public Assistance Committee invite applications for the above post at the Hospital, Alma Road, Rotherham.

Salary £150 per annum, together with usual residential allowances.

Candidates must be single, not exceeding 30 years of age, fully qualified and registered.

The appointment will be for the period of one year in the first instance.

Applications, stating age, qualifications, etc., together with copies of three testimonials, to be sent to the Public Assistance Officer, 26, Moorgate Street, Rotherham, not later than June 7th.

Municipal Offices, CHAS. L. DES FORGES,

Administrative County of LONDON.

HOSPITAL SERVICE.

The LONDON COUNTY COUNCIL invites applications from qualified Medical Practitioners for appointments to positions in the undermentioned Hospitals. Candidates must be single and have had previous residential Hospital experience. The persons appointed will be required to carry out such duties as may be assigned by the Medical Superintendent, and, should occasion arise, to assist at any of the other establishments or medical districts under the control of the London County Council.

(a) Bermondsey and Rotherhithe Hospital, Lower Road, Rotherhithe, S.E.16. ASSISTANT MEDICAL OFFICER, with Surgical experience. Provisional commencing salary £400 a year, with free board, lodging, and laundry.

(b) Hackney Hospital, High Street, Homerton, E.9. SENIOR ASSISTANT MEDICAL OFFICER (Physician). Provisional commencing salary £400 a year, with free board, lodging, and laundry.

(c) Paddington Hospital, 285, Harrow Road, W.9. ASSISTANT MEDICAL OFFICER, with experience in the care of Medical Wards and the administration of Anæsthetics. Provisional commencing salary £330 a year, with free board, lodging, and laundry.

(d) St. Leonard's Hospital, Hoxton Street, N.1. THIRD ASSISTANT MEDICAL OFFICER, with Surgical experience. Provisional commencing salary £400 a year, with free board, lodging, and laundry.

(e) St. Stephen's Hospital, 369, Fulham Rd., S.W.10. ASSISTANT MEDICAL OFFICER. Provisional commencing salary £360 a year, with free board, lodging, and laundry.

The salaries and conditions of appointment in each case are subject to review by the Council. Appointments will be subject to the Council's regulations under the Superannuation and Provident Fund except as provided in the Local Government Act, 1929.

Forms of application may be obtained from the Medical Officer of Health (Staff Division), The County Hall, Westminster Bridge, S.E.1. A stamped addressed envelope should be enclosed, and forms must be returned by Friday, May 30th. Canvassing disqualifies.

Candidates desiring to apply for more than one appointment must send in a separate form of application in respect of each Hospital. Inquiries for any further details as to the nature and scope of the duties at the individual Hospitals should be addressed to the Medical Superintendent of the Hospital concerned.

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. WEST END.—Well-established good-class non-dispensing and non-panel PRACTICE, worth last year nearly £1,500 and offering considerable scope. Visits 10/6 (very few), £1 1s., and 3 for £2 2s. Practically no midwifery (discouraged). Expenses light (car not kept) and no bad debts. Exceptionally well-situated ground floor Flat, with good accommodation. Rent on long lease (which is valuable) £350. Premium £3,500. Introduction for 12 months given.
2. SOUTH DEVON.—COUNTRY PRACTICE, steadily increasing, and situated in very pleasant agricultural district, within easy reach of coast. Gross cash receipts for past 12 months £2,326. Panel produces, with mileage, about £420. Fees 3/6 to 21/-. Only about 20 cases of midwifery from 2 to 5 gns. Suitable house, in main street, with 2 reception, 5 bedrooms, etc. Garden. Garage. Rent on lease £50 p.a. Good sport. Premium £2,800.
3. LONDON, NORTH.—Old-established working-class PRACTICE, in well-populated district. Cash receipts for last financial year nearly £1,400, including panel of over 2,000. Practically no midwifery. Expenses very small. Double-fronted house in good position (2 reception, 2 bedrooms, bathroom, etc., and professional accommodation). Rent on lease (12 years to run and renewable) £80 p.a. Premium £3,000.
4. SOMERSET.—Attractive Town, within easy reach of coast.—Old-established and increasing PRACTICE, producing for the immediate past twelve months over £3,000, including panel of 1880, and appts. worth about £250. Fees 2/6 to 21/-. Cottage Hospital, and good surgical scope. Two very suitable houses available at very moderate rents. Sport of all kinds. Premium £4,500.
5. SOUTH OF ENGLAND (Thriving Seaport Town, pop. over 30,000).—Old-established mixed-class PRACTICE, averaging at present £500 p.a., but offering exceptional scope. Panel of about 430 and 2 small appts. Visits 3/6 to 5/-. Practically no midwifery. Very attractive residence, on main road and near the sea, with professional rooms, 2 reception, 4 bedrooms, bathroom, etc. Pretty garden. Garage. Rent on lease £100 p.a. Premium 1½ years' purchase.
6. WITHIN TEN MILES OF GLASGOW.—Prosperous old-established good middle and better-class PRACTICE, producing an average of nearly £2,950 p.a., including panel of 2,300 and appts. worth £500. Fees 2 extra. Mid. from 2 gns. upwards. Very good 3 reception, 5 bedrooms, etc. Garden. Garag or other residence secured. Premium 1½ years' purchase, £1,500 down, and balance as arranged.
7. PARTNERSHIP.—MIDLANDS.—COUNTY TOWN.—TWO ONE-FIFTH SHARES (suitable two friends or will be sold separately) are offered in a very old-established good mixed Practice owing to the retirement of the senior of two partners. Gross cash receipts for immediate past 12 months over £5,900, including panel of 3,400. Fees from 4/-. Not much midwifery. Good house, with 2 reception, 6 bedrooms, etc. Rent on lease £75 p.a. Premium for share two years' purchase.
8. SOMERSET COAST.—In a small but increasing and delightful seaside resort, the five-twelfths share of a very old-established PRACTICE, producing last financial year £1,600, but offering exceptional scope. Panel brings in £480 and appointments. Visits 5/- to 4 guineas. Mid. 4 to 6 gns.; only about 12 cases yearly. Choice of 2 suitable houses (price, freehold, £950), with gardens. Electric light and gas. Premium 2 years' purchase.
9. SOUTH-WEST COAST.—VERY FAVOURITE RESORT.—Old-established good middle-class non-panel PRACTICE, held by Vendor (who is retiring) over 20 years. Receipts average £1,142. Fees 5/- to 10/6 and upwards. Mids. 5 to 15 gns. (about 12 cases). House is an exceptionally good one, in perfect order, with ample accommodation, central heating, electric light. Good garden. Garage. Price for freehold £3,250. Premium 1½ years' purchase.
10. CORNISH RIVIERA.—Old-established good mixed PRACTICE in exceptionally attractive village which is steadily increasing. Receipts for last 12 months £1,300, including panel of over 400. Visits 5/- to 21/-. Excellent house, facing due south, with 6 bedrooms, etc. Good garden. Rent on lease £56 p.a. Premium £1,800.
11. YORKS (NORTH RIDING).—In a small pleasant market town, with pretty and prosperous surrounding country, very old-established mixed-class PRACTICE averaging £1,247 p.a., including appts. worth £80 and panel producing last year £366. Visits 3/6 to 25/-. One opponent. Good house, facing south (3 reception, 5 bedrooms, bathroom, etc.). Garden. Garage. Electric light. Vendor's freehold. Price £1,350 (£1,000 on mortgage), or would let for few years at £80 p.a. Premium £1,500. Educational and social amenities.
12. SOUTH YORKS.—GOOD TOWN. — Old-established good middle-class PRACTICE, producing for last twelve months nearly £4,500. Small selected panel of 400. Fees 5/- to 10/-. Mid. 2 to 10 gns. (only about 50 cases yearly). Suitable house, with 3 reception, 6 bedrooms, etc, and professional rooms. Electric light. Good garden. Garage for 3 cars. Rent on lease £100 p.a. Excellent schools, sport, etc. Premium £5,700.
13. KENT.—Pleasant Seaside and residential Town (pop. 17,000).—Old-estab. non-dispensing middle and working-class PRACTICE, averaging for the past 3 years over £1,050 p.a. including transferable appt. worth about £200 and panel of 500. Visits 3/6 to 10/6. House contains 8 rooms, kitchen, bathroom, etc. Garden. Garage. Price freehold £1,500, but might be rented. Premium £1,500.
14. DEATH VACANCY.—CORNWALL.—Good mixed general PRACTICE, in very pretty district, producing over £1,200 p.a., including panel of 845. Fees, from 2/6. Mids. from 2 gns. Rent of Surgery 15/- per week. Small house available, rent £20 p.a. Premium £850, payable £200 down and balance of yearly instalments of £150.
15. DEATH VACANCY. — HARROGATE. — Well-established PRACTICE, averaging about £600 p.a., including panel of 500. Fees 3/6 to 21/-. House contains 2 reception, 5 bedrooms, etc. Price £1,000, or might be rented. Moderate premium. Locum in charge.
16. LINCS.—Very old-estab. easily worked Village PRACTICE, averaging £1,335 p.a., including panel and appts., producing £740 p.a. Fees from 2/6. Not much midwifery. Nearest opponent 6 miles. Suitable house, with 3 reception, 4—5 bedrooms, bathroom, etc. One acre of garden. Price £900. Good sport and schools within reach. Premium 1½ years' purchase. Cottage Hospital.
17. MANCHESTER.—PRACTICE is situated in a growing district offering very large scope. Income about £1,700 p.a., including panel producing £430. Fees 3/6 upwards. Excellent detached house, well situated, with 3 reception, 5 bedrooms, etc., all in good order. Price £1,800. Premium 1½ years' purchase.
18. HANTS.—COUNTRY PRACTICE.—Very old-established, situated in most attractive district near Sussex Border. Receipts average over £800 p.a.. Panel of 480. Detached house in half an acre of garden, 2 reception, 5 bedrooms, etc. Rent £55 p.a. Hunting, golf, etc., and first-class schools within reach. Premium £1,300.
19. LONDON, SOUTH-WEST.—Very old-established non-residential PRACTICE, averaging about £4,000 p.a. Panel of 1,500, but large scope for more. Fees 2/6 upwards. Suitable house or flat can easily be obtained to meet purchaser's requirements. Rent of surgery on long lease £100 p.a. Premium 1½ years' purchase.
20. YORKS.—In a clean and thriving manufacturing town, an old-established Homœopathic and partly Allopathic PRACTICE, held about 50 years by Vendor who is retiring. Cash receipts for the past three years average £2,400 p.a. Patients middle and better-class. Midwifery refused. Good house available, rent £100 p.a. Premium only one year's purchase, part down and balance by arrangement.
21. LANCS.—LARGE TOWN.—Very old-established good industrial class PRACTICE, producing £2,500 p.a., including panel of 1,804, and appts. worth about £120 p.a. Fees 2/6 upwards. Very suitable for two friends in partnership, as two houses available. Good sport and schools. Premium 1½ years' purchase. A one-half share will be offered with view to succession in six or twelve months if desired.
22. CHESHIRE.—Industrial Town within easy reach of Manchester.—Well-established PRACTICE producing £2,600 p.a., with panel of 2,870. Fees 2/6 to 3/6, medicine extra. Good house, with ample accommodation. Price £1,000, or would be rented at £70 p.a. Premium 1½ years' purchase, half down and balance by instalments.
23. SOUTH OF ENGLAND.—LARGE SEAPORT TOWN.—Old-established mixed general PRACTICE. Average income nearly £1,900. Panel of 2,500. Fees 2/6 to 7/-. No mids. No Assistant kept. Well-situated house, with good accommodation. Rent on lease £120. Prem. £3,300.
24. WITHIN 40 MILES OF LONDON.—In a thriving Riverside and Hospital town (pop. over 40,000).—Old-established mixed-class and increasing PRACTICE worth over £2,300 last year, including panel of 1,600 to 1,700. House contains professional accommodation, 2 reception, 4 bedrooms, bathroom, etc. Small garden and garage. Rent on lease £60 p.a. Premium £3,650, to include good book debts of £500, drugs, etc., and consulting room and surgery furniture.
25. BORDERS OF BERKS AND HANTS.—In a delightful district, an old-established mixed-class PRACTICE averaging for the past three years £904 p.a. (last year £973), including panel of 400. Visits 5/- to 12/6, medicine extra (3/6). Very little midwifery. One opponent. House contains ample accommodation (2 sitting rooms, 7 bedrooms, bathroom, etc.). Large garden and garage. Water laid on and gas plant installed. Rent £50 p.a. Premium £1,400. Excellent sport.
26. PARTNERSHIP.—WEST MIDLANDS.—The Third share (with increase to half in 4 years and eventual succession if desired) is offered in very old-established mixed-class Practice in small town, largely residential, in midst of agricultural district of exceptional beauty. Cash receipts average £2,367 p.a., including panel of 1,084. Opposition not strong. Expenses light. Choice of two houses (small) which can be bought for £600 or £700. Premium 2 years' purchase.
27. SURREY.—In a beautiful residential district within 40 miles of London (good train service) a small mixed-class PRACTICE worth about £600 p.a. and offering scope. Select panel of 200. Charming house with ample accommodation in very pretty grounds (tennis court, etc.) of 1¼ acres. Price, freehold, £3,500. Premium 1½ years' purchase.

The "Allenburys"

"CHARKAOLIN"

GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of "Osmo" Kaolin.

It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

BELLE VUE SPA

TREFRIW, NORTH WALES.

(Railway Station: Llanrwst and Trefriw.)

COMBINED TREATMENT OF ARTHRITIS

By Chalybeate Waters, Tonic Baths and Extension Appliances

The Belle Vue Spa Hotel provides accommodation for patients for whom these tonic chalybeate waters are indicated. External treatment by tonic baths, as well as by manipulation and extension and light, is also provided.

Recent analyses of the Belle Vue Spa waters show that they are exceptionally rich in ferrous salts. Samples have been repeatedly examined by the Clinical Research Association.

A new building furnished with Baths and all modern Electrical Appliances for treatment was opened last Saturday, April 26th.

Under expert advice the drinking service of the Belle Vue Spa water is now taken from selected sources in the water-yielding rock, and served fresh at the Spa at a standard strength of 1 grain of ferrous sulphate in one ounce.

For patients who are unable to visit Trefriw and take the water on the spot, it is bottled and exported at the same standard strength for medical use in their own homes.

In suitable cases of arthritis and rheumatic disease Hoefftcke's manipulative and ambulatory extension treatment can be applied.

Mobility and freedom from pain in crippling arthritis of the hip and knee can often be obtained, even after shortening and contraction have occurred. This is effected by the extension appliances, which maintain continuous extension by day and by night. The appliance usually permits the patient to walk, and not only supports the weight but replaces the undesirable state of compression of the leg by one of active stretching.

This method secures:—

(1) Extension without muscle loss, inevitable whilst the patient is kept in bed.
(2) Extension without vascular stasis, which occurs when a joint is kept at rest.
(3) MOVEMENT WITHOUT PAIN.

The result has been a restoration of joint function in many cases which had been regarded as hopeless and incurable. The Spa is under medical supervision and close co-operation is maintained with the patient's own physician.

Further particulars may be obtained at Belle Vue Spa or 7, Harley-Street, W.1.

Apply: **The Secretary, Belle Vue Spa, Trefriw, North Wales.**

Telegrams: BELLEVUE, TREFRIW. Telephone: LLANRWST 60.

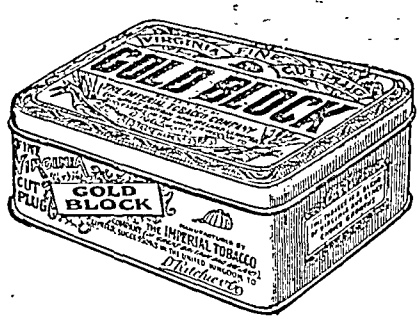
Over Two Million Pounds Sterling

1907-1930

THIS very large sum represents the value of Whole Life, Endowment, Children's Educational and Thrift Policies effected by members of the profession through the Agency since it was founded 23 years ago. The general satisfaction of those who have consulted the M.I.A. is evidenced by the fact that in all the thousands of Policies selected and negotiated by the Agency not a single complaint has been received.

The M.I.A. offers free, expert, and unbiassed advice on all classes of Assurance and Insurance.

You can profit by this advice, and, incidently assist the cause of the Medical Charities, to which the Agency has already subscribed over £23,000.



Whether your interest is directed to LIFE, SICKNESS, HOUSEHOLD, MOTOR CAR, or any other form of insurance, it will be to your advantage to seek the assistance of the Agency in

WE GUARANTEE THE REPURCHASE PRICE OF THE CAR YOU BUY

Because a car is so necessary to the practice, its cost should be calculated as a professional expense. Our guaranteed repurchase plan makes this calculation a comparatively simple one. You let us know the make and type of car you prefer and we send you a list of suitable cars. Before you buy, we guarantee to repurchase the car at an agreed price at the end of an agreed period. The period, like every other condition of this plan, is arranged to suit your convenience. After purchase, the car is yours. There are no inspections, no irksome conditions, and no restrictions on mileage. This plan fixes the cost of ownership because it avoids the risk of loss at resale. It is cheaper than hiring, you enjoy the benefit of the full ownership and you may change your car just when you please. Finally, because it is planned with a sure knowledge of what is helpful and necessary, you will find our Guaranteed Repurchase Plan infinitely convenient. May we send you full details of this service? They are awaiting your enquiry.

THE ONLY SUPPORT

Giving direct abdominal uplift

Maintained in any position that the patient may assume without any cramping or binding of the hips whatsoever. The principle is that of a direct anterior-posterior pressure, and enjoys numerous advantages over any other make of support on the market. It is simply fastened by a strap and buckle, and can be adjusted to any degree that the physician may prescribe.

SOLID IODINE

Safe—useful—portable

The manifold uses of H_2O_2 are known to all members of the medical profession. 'Peroxtik' is the only solidified form of Peroxide of Hydrogen in existence. Its utility, portability and safety is obvious, and every tube is guaranteed to maintain its original 10-volume strength for a reasonable period. Medical men interested in H_2O_2, who are desirous of testing 'Peroxtik,' should not fail to write for a free sample tube to ARTHUR H. COX & Co., LTD., 93, Lewes Road, Brighton.

'Peroxtik'

SOLIDIFIED PEROXIDE OF HYDROGEN

in neat, handy glass tubes.

Suppresses putrefaction and bacterial infection of the colon

Lactose and Dextrin owe their value in changing the intestinal flora to the fact that they are more slowly absorbed than other carbohydrates. Because of this slow absorption they are able to reach the colon in sufficient quantity to cause a luxuriant growth of productive flora, thus keeping down putrefactive and poison-forming germs. Lacto-Dextrin effectively disposes of the disadvantages of both Lactose and Dextrin in their crude form. It is a palatable and agreeable combination of the two, and is highly efficient in producing the growth and development of both B. acidophilus and B. bifidus in the colon.

Samples and literature will be sent on request to the Medical Profession on application to Sole Distributing Agents for U.K. and Irish Free State. COATES & COOPER. 41, Great Tower Street, London. E.C.3

PEAT in the TREATMENT of SKIN DISEASES

THE effectiveness of the peat distillate principle in the treatment of skin diseases is sufficiently well known to need no comment. Sphagnol preparations contain this principle in a convenient medium. The medical soap, the ointment, the lotion, the suppositories allow of your using the properties of peat in the manner most suitable to the case in question.

The manufacturers make no more extravagant claim than this. They simply state that Sphagnol preparations provide the peat distillate principle in a convenient medium, and that they can be purchased for a reasonable price at any chemist's shop. They are prepared to submit samples for you to judge their claims. If you are a medical practitioner simply write to Peat Products (Sphagnol) Ltd., (Dept. B26), 21, Bush Lane, London, E.C.4.

If it bear any of the Trade-Mark names:

Independent Evidence by a Leading Professional Journal.

56 THE NURSING MIRROR AND MIDWIVES' JOURNAL. APRIL 19, 1930.

The Nurses' Materia Medica.
A GUARANTEED GUIDE.
By Our Analytical Experts.

No. 16.—ROBOLEINE.

HAVING heard a good deal of the virtues of Roboleine as a good "body-builder" in cases of malnutrition, we selected a sample of this food for analysis by our experts this week, as we desired to know whether it was really as good as it was reported to be. The result has proved that its makers, Oppenheimer, Son and Co., Ltd., are justified in claiming that it contains all the vitamins at present known to medical science, and that it is an excellent digestive food. The sample analysed was found to contain the following:—

	Per cent.
Moisture	23.28
Fatty matter	4.04
Mineral matter	1.72
Phosphate as P_2O_5	0.78
Nitrogen	0.06
Equal to protein (Factor 6.38) ...	0.38
Maltose	52.00

Lecithins and citralis were also present.

Roboleine is no new product. It has been in use for fully a generation, and proved itself valuable over and over again in cases of debility, loss of weight, malnutrition, sleeplessness, and especially so in tuberculous conditions. Nursing mothers have found both the quantity and quality of their milk improved by taking it, and for artificially fed babies it makes a useful adjunct in the diet. Full directions as to dosage are issued with each bottle, and nurses may feel quite safe in taking it themselves when feeling a little run-down, or in recommending a course of it to the convalescent patient just leaving their care. After influenza, typhoid fever, or any wasting condition, Roboleine should be taken regularly for three or four weeks while strength is returning.

The extract given shows the result of an independent analysis on a sample of **ROBOLEINE** purchased in the open market and made by the expert analysts advising a leading professional journal. The report shows that **ROBOLEINE** contains all the vitamins, and it confirms all the claims made for **ROBOLEINE** by the manufacturers, both as a body-builder and an anti-infective.

The Food that builds the Body.

HOW GIBBS HELPS THE DOCTOR

Gibbs takes the Oral Hygiene Message into the British Family Circle

A great deal of good would be done if every Doctor in Great Britain could find time to have a talk with all his patients at very regular intervals upon dental matters. An impossible task—and, happily, not altogether necessary. Gibbs nation-wide advertising and their intensive educational work is doing far more for each Doctor's charges than he could possibly do himself.

At least once a week—often every day—in some homes, almost every hour—some message about dental hygiene is delivered by Gibbs in every family circle in Great Britain.

Always it is just such a message as the Doctor himself would give if he could be there in person—a reminder to clean teeth regularly—a warning to see the Dentist at the least sign of anything being wrong—a word as to the importance of right diet in making good teeth and keeping them sound—a hint that once at least in six months a dental examination is very desirable.

Every stratum of society is reached—men, women and children are told how—with the help of the Dentist—they can be sure of perfect teeth all their lives.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates, Bridgework (both gold and vulcanite) and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

Gibbs Dentifrice

MONSOL in MIDWIFERY

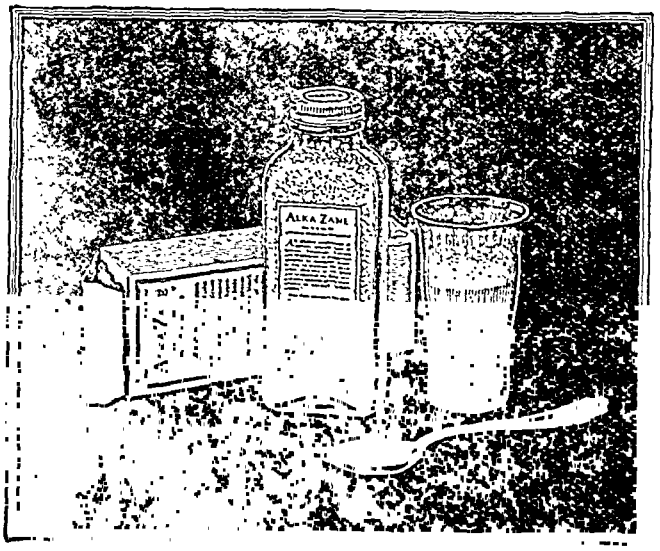
An authority on the subject has expressed the considered opinion that the use of Monsol in midwifery would reduce the incidence of Puerperal Sepsis by fully 90 per cent.

Bacteriologists and Clinicians have proved repeatedly that Monsol has a selective action on Streptococci—an action ten times greater than lysol (which cannot destroy these germs except at a concentration liable to injure the tissues).

Outstanding features of Monsol are:

1. A high germicidal power against the organisms that cause sepsis.
2. A bland and emollient action—non-irritating to the tissues and mucous membranes at therapeutic concentrations.
3. Low toxicity. (One-sixth as poisonous as lysol.)
4. Great powers of penetration, reaching deep-seated inflammation.

Many Hospitals, Nursing Homes and Lying-in Institutions are now specifying the use of Monsol in all maternity cases. In addition to reducing the risk of infection, Monsol leaves the hands and skin soft and supple, a fact much appreciated by the Nursing Profession.



Monsol is the product of a Mond Laboratory, prepared under strict scientific control.

Monsol Toilet Soap 8d. Monsol Throat Pastilles 1/3 & 2/3. Monsol Dental Cream 1/-. Monsol Ointment 1/3 & 2/-. Monsol Liquid Germicide 2/-.

Manufacturers: The Mond Staffordshire Refining Co., Ltd., Abbey House, London, S.W.1. Trade enquiries to: The Monsol Distributing Agency, 168/172, Drummond Street, London, N.W.1.

MONSOL
THE SAFE GERMICIDE

In Hyperchlorhydria

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

and other conditions of gastric over-acidity, Alka-Zane will afford prompt relief from distressing symptoms and restore normal alkaline balance.

Diuretic and antacid, Alka-Zane is indicated wherever the alkali reserves are unduly depleted, as in intestinal disturbances, rheumatic affections and certain anaphylactic manifestations.

Prepared by WILLIAM R. WARNER & CO., INC.,
Manufacturing Pharmacists Since 1856.

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

Nujol

REGISTERED TRADE MARK.

Nujol Department, 128, Albert Street, Camden Town, London, N.W.1.

For the Treatment of Haemorrhoids

SANUSIN SEMPULES B.D.H.

The sempule is an improved form of suppository, specially moulded so that a small portion remains external to the anal sphincter after insertion: the medicament is thus retained at the seat of the disorder until completely melted, thereby assuring its prolonged application and greater absorption. Herein lies its distinct superiority to the usual type of suppository which does not remain in situ, but which passes on and melts in the rectum—thus failing to produce the local effect desired in the treatment of haemorrhoids.

Sanusin Sempules contain resorcin, boric acid, balsam of Peru, zinc and bismuth carbonate—a combination of substances which has great antiseptic and healing power.

Sanusin Sempules have been found effective in many cases which have resisted other methods of treatment.

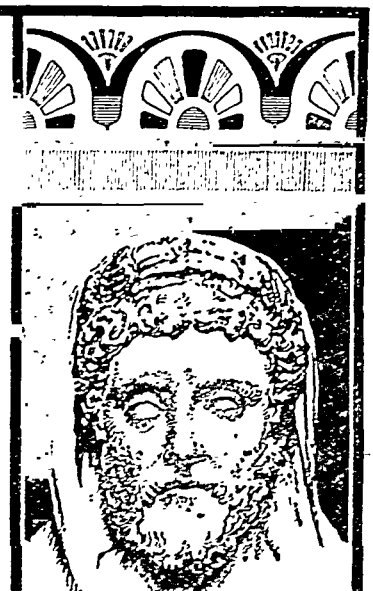
In Infancy

WHETHER the child be breast-fed or bottle-fed, constipation is often a troublesome feature. Castor oil and other purgatives, or aperients, while securing a prompt action of the bowels, possess certain definite disadvantages with which the practitioner is fully acquainted.

"Cristolax," a combination of 50% of the purest medicinal paraffin of correct viscosity and 50% "Wander" Dry Malt Extract, is of special value for infants, particularly for those who are artificially fed.

One teaspoonful dissolved in three feeds a day, no matter whether they consist of milk or infants' food, renders the feeds more easily digestible, prevents the formation of hard indigestible clots, and keeps the bowels in a regular and sweet condition.



"Cristolax" is also an admirable preparation for the nursing mother, both during gestation and the lying-in period. Its use ensures regular and adequate defecation without griping, straining, or harmful effect upon the child.

Medisoap Therapy

DISEASES OF THE SCALP.

In the treatment of scalp conditions Medisoap Therapy merits special consideration, as the presence of hair complicates most other schemes of treatment.

℞. Medisoap Midgley No 41

In this formula is presented a useful combination of resorcin, salicylic acid and sulphur—Resorcin is one of the least toxic of the dihydric phenols. Although not so powerful an antiseptic as carbolic acid, it is less irritant and caustic. It is used for many types of skin diseases, and in the above combination is of value in cases of seborrhoea, dandruff, alopecia, and other affections of the scalp.

SECTION OF THE BASILICA OF SANTA SOPHIA, DEMONSTRATING THE CONSTRUCTIVE PRINCIPLES UPON WHICH THE BUILDING OF THE MOST CHARACTERISTIC BYZANTINE MONUMENT IS BASED.—With Santa Sophia, Byzantine architecture "springs almost at once into full glory." The cupola was not new to the world, neither was the basilica, but the domed basilica, the result of the combination of pre-Byzantine building types, was the achievement of architects working in Constantinople. Never had this experiment been attempted before upon a large scale. The carrying of the weight of the enormous dome, 21 metres in diameter, was the chief problem. This was solved by constructing, upon a square base, four massive columns, which were made to support four great vaulted arches and the spherical pendentives between them. Upon these rests the huge dome, so lightly, to all appearance, as to seem "suspended by a golden chain from the sky above," this effect being heightened by a circle of windows round its base. Two spacious apses preserve its equilibrium. It has to be related, however, that the first dome proved too audacious an experiment. It fell after 21 years, causing consternation throughout the empire, whose pride it was. No time was lost and no effort spared in rebuilding it, with its weaknesses remedied. The monument has endured nearly fourteen hundred years and is still one of the wonders of the world.

1930 TALKS
No. 1.

"The Lancet" in its Reports and Analytical Records has said of Ryvita Crispbread:—

"There is more character in the flavour of Rye than of wheat, and the food value of the former (rye) needs no comment.

"On analysis (of Ryvita) the following results were obtained:—

	Per cent.
Carbohydrates, altered starch, hemicellulose, etc.	74.8
Protein	11.6
Moisture	9.0
Ash	1.8
Fat	1.3
Fibre	1.5

Calorie value per lb., 1662.

"Ryvita Crispbread, which keeps well and does not readily become 'slack,' is easily masticated and digested, and is a useful and palatable addition to the diet. The calorie value shows it to be a concentrated form of food."

* * *

Ryvita Crispbread is a most appetising form of bread—crisp, crunchy, and delicious. It is made of pure, crushed, wholegrain rye, and is a complete cereal food, not only because of its perfectly balanced food elements but also because, mechanically, its natural fibrous form is an actual aid to the functional processes of digestion, assimilation, and elimination.

Ryvita is rich in the natural organic salts of iron, phosphorus, and lime, and is therefore a valuable body-building food. It is balanced by its own B Vitamin, because owing to a difference in the structure of rye grain the germ cannot be lost in the milling as it so often is from wheat or oats.

Many Doctors make Ryvita Crispbread their own daily bread, and recommend it enthusiastically to their patients. Ryvita is definitely indicated as an item of the dietary in treatment of disorders arising from digestion, constipation, or malnutrition.

It is usual to suggest that the patient begin by eating two or three slices of Ryvita with one meal each day.

We shall be very pleased to send Free Samples and full particulars to any interested Member of the Profession.

Observations ON

ASTHMA: RESULTS OF TREATMENT.

BY

D. M. LYON, M.D., D.Sc., F.R.C.P.ED.,
PROFESSOR OF THERAPEUTICS AND CLINICAL MEDICINE, UNIVERSITY OF EDINBURGH;

AND

R. M. MURRAY-LYON, M.D., M.R.C.P.ED.,
EDINBURGH.

GENERAL impressions gained from clinical experience, though sufficient for the individual observer, should be confirmed by definite evidence whenever possible. A series of nearly 500 cases of asthma examined in the Royal Infirmary of Edinburgh seemed to offer an opportunity of obtaining information regarding the course of the disease and of the results which may be expected from treatment. A preliminary analysis of these case records has already been published.[1] The patients were all recommended to the hospital by their own doctors as cases of "asthma." The majority of them were examined as out-patients, while a proportion of the more severe cases were treated in the wards for a time. A diagnosis of "asthma" was based on the finding of the patient's own doctor, and on an examination of the individual and a careful history of his illness. Cases of dyspnoea dependent on obvious cardiac or renal disease have not been included. On the other hand, patients with marked bronchitis have only been accepted as asthmatic when a definite account of paroxysmal attacks of dyspnoea was forthcoming. Exception may be taken to the inclusion of cases which have developed asthmatic symptoms only after a long history of chronic bronchitis, but it has been found impossible to draw a hard-and-fast line. There is a tendency on the part of medical writers at the present time to regard "true" asthma solely as a manifestation of the allergic syndrome and to set aside, as not being asthma, cases in which the presence of allergy could not be proved. True asthma, then, would include those cases which show a positive inheritance of asthma, hay fever, or one of the other exudative diseases, and those in which sensitiveness to some protein can be demonstrated, while patients who only develop asthmatic symptoms after severe or repeated attacks of bronchitis are merely regarded as "asthmatic bronchitis." It has not been possible for us to make such a distinction on account of the large part which respiratory disorders play at the onset of true asthma even in early life; in addition, evidence of constitutional predisposition is often found in cases of late development. All our cases have therefore been taken together as examples of the asthmatic syndrome.

The Edinburgh inquiry has now been in progress for about nine years, a steady stream of patients coming for examination and advice at all seasons. As an estimate of the value of treatment can be made only after a sufficient interval, it has been decided to leave out of this survey all patients seen for the first time within the past twelve months. This leaves a total of 379 patients about whom we have endeavoured to obtain information. The short, simple questionary employed has been completed in some cases by the sufferers themselves, in others by their medical attendants. Many of the patients have recently reported in person, giving us an opportunity of obtaining more detailed information. For various reasons it has been impossible to trace 88 of the patients, chiefly because of change of residence, which appears to be more frequent than has been suspected. Replies concerning 291 patients have been received. These records reveal that 36 patients have died; 63 state that their asthma is still as bad as ever; the remaining 192 have derived benefit from treatment. These may be divided into four classes according to the degree of improvement. No fewer than 63 claim to have been "cured," by which is meant that they now enjoy complete freedom from attacks. Some of them have been in good health for years. Those "improved" but not cured number 129. Very great improvement is recorded by 60 patients, many of whom have now only occasional attacks, and these usually mild in character. The third class—those much improved—contains 57 individuals, while only 12 record their improvement as slight. It will thus be seen that a large proportion of the asthmatics still living have received substantial benefit from treatment. The "improved" and "cured" together total 65 per cent. of the whole. Reports concerning those now dead show that some in this group had improved or were free of asthma for a time before death, and that they died from some other condition unconnected with asthma.

While these results are highly encouraging, it is clear that no definite improvement can be guaranteed to an individual sufferer. Many cases are readily amenable to treatment; others appear to be quite resistant, and superficially it is not obvious why this should be so. These differences in the results obtained stimulate inquiry into the factors which lead to them. The points of importance in this connexion appear to be: (*a*) the form of treatment employed; (*b*) the age at which symptoms originally appeared; (*c*) the duration of the asthma before satisfactory treatment is begun; (*d*) the patient's age when first seen; and the questions of (*e*) heredity; (*f*) sensitization; and (*g*) the relation to respiratory infections. Attempts to classify patients according to the severity of the disease have not been successful. The gravity of the condition is difficult to assess for statistical purposes. Patients vary so greatly in their estimates of what constitutes a severe or a mild attack, and the frequency of asthmatic paroxysms is often so variable throughout the seasons, that comparison of one case with another is almost impossible. The physical condition of the patient and the presence or absence of other disease also have considerable influence upon the ultimate result, but the information recorded on these questions is not sufficient to enable an analysis to be made.

Relation of Treatment Employed to the Results Obtained.

Since asthma is such a variable disorder, and individual cases differ so greatly, it is impossible to lay down a uniform plan of treatment for all types. Patients must be treated individually. The clinical examination usually indicated what lines of therapy would be most successful, and an appropriate scheme was drawn up for the patient. Instructions regarding general hygienic measures, alterations of diet, avoidance of late meals, attention to the bowels, and so forth, were given at the time of the examination. The principal treatment was, in many instances, carried out under the supervision of the patient's own doctor. Those who suffer from such a chronic and distressing malady as this are apt to become dissatisfied with one line of treatment and try one remedy after another. Where information on this point has appeared of importance it has been included in our analysis. The figures for treatment have been compiled from the patients' answers to the questionary, checked and supplemented from our records.

The recognition of a specific causal agent and its removal or avoidance is clearly the most satisfactory line of treatment when it is applicable. Sometimes the matter is extremely simple and a relatively slight modification makes all the difference. Such minor adjustments are apparently not considered of importance by the patients, for they are seldom mentioned in the returns. Avoidance of an irritant plant or removal of a domestic pet can easily be arranged, but when the irritation arises from some common protein which cannot readily be eliminated, recourse may be had to specific desensitization. Such specific irritants have not been numerous in this series, but the results of their removal have been striking. In the majority of cases in which elimination has been practised the patients have been completely relieved of symptoms.

The importance of environment in aggravating or in relieving symptoms of asthma is well recognized by the general public, and many of our patients (86) have sought relief in a change. Rather more than half of this group found their condition to be just as bad in their new surroundings: two patients believed that they became definitely worse; but 45 per cent. of those who changed their residence claimed improvement thereby. A few asthmatics claimed that they had obtained complete relief

from symptoms as the result of changing their surroundings.

Examination of the nose and throat has been carried out in the majority of the patients (252). Most of the subjects were found to show some abnormality, though not necessarily severe enough to require treatment. While remarkable cures may occur after nasal operations, experience shows that such results are exceptional, and caution is necessary in recommending this class of treatment. It is safer never to suggest an operation as a cure for asthma, but only to recommend it when it appears desirable for other reasons—for example, to remove a definite obstruction or to lessen a tendency to recurrent catarrh. In spite of this conservative attitude, 115 patients have been operated on. The operations include 67 for tonsils and adenoids, 18 for polypi, 24 for turbinectomy, 14 for submucous resection, and, in addition, cauterization has been carried out when considered desirable. These procedures undoubtedly benefited the patients by removing irritation or sepsis and by giving a freer airway, and so have contributed to the general results of treatment. Our figures do not show this very clearly. Of patients upon whom operations were performed 18.3 per cent. are returned as cured, in contrast to 29.4 per cent. of cures among those who had no operation. When the "cured" and "improved" are taken together the position is reversed, the figures 66.9 per cent. and 63.2 per cent. showing a small advantage in favour of those who had undergone operation.

Since respiratory infections play so large a part in relation to asthma, either as causal agents or as secondary complications, their treatment including avoidance of prophylaxis is of great importance. Where this factor seemed to be prominent, the patient was given a course of autogenous vaccine made from a laryngeal swab. The results of this treatment have been most gratifying. Patients have not only suffered less from colds, but after the course of vaccines have often had complete freedom from asthma for some time, or no further return of symptoms. It is significant that the proportion of cured and improved patients who received vaccine treatment is distinctly higher than that of the unfavourable groups. A few of the more resistant cases have undergone treatment by diathermy, ultra-violet radiation, or by x rays, with apparent benefit.

Probably all the patients at some time or other have received drug treatment, yet only half of the returns (153) include this item. The figures given in the table for each group form an interesting commentary on the value of drugs as curative agents, favourable cases showing less than the others. This may be merely that, having failed to benefit from other measures, the unresponsive patients have had greater opportunity for trying such remedies. Though it is interesting to find that the patients who were cured received less drug treatment and a higher proportion of vaccines, and that the position with regard to patients who were not cured is reversed, too much weight must not be given to these figures, since they also reflect to some extent the types of case dealt with.

Age at Onset.

The average age at onset of the asthmatic symptoms is much the same in all the groups, except the fatal cases, which have a much higher age-incidence (see table). It is found that in about a third of all the cases (35.4 per cent.) the onset occurs in the first decade. Taking the patients who began to suffer in the first five years of life it will be found that the number "cured" is somewhat low, while the proportion of "unchanged" is relatively high. These differences do not hold for the second quinquennium, nor up to middle life, but a large proportion of the cases commencing after the age of 40 are also unfavourable; 66 per cent. of those who became asthmatic late in life are in the two lower categories. From these observations it would seem that the prognosis is not so good in cases commencing in the first five years, or after middle life.

Duration of Asthma before Treatment.

The length of the illness before the patient came to the clinic has varied greatly. While most of the patients had suffered for a short time only, some had had the disease for a longer period, and 10 had been asthmatic for over thirty years. Of all cases of less than five years' standing when first seen, no less than 32.6 per cent. were cured, while the percentage "unchanged" numbered only 14.0 per cent. These figures may be compared with the proportion that the "cured" and the "unchanged" bear to the whole

	Cured.	Improved.	Unchanged	Dead.
Number of cases	63	129	63	35
Average age at onset (years) ...	21.5	17.5	20.4	31.4
Average duration (years) ...	7.3	10.6	10.6	10
Age at onset:	Per cent.	Per cent.	Per cent.	Per cent.
0–5 years	15.9	19.4	27.0	8.6
Over 40 years	12 7	7.5	20.7	40.0
Duration 0–5 years	44 4	25.6	19.4	37.1
Heredity positive...	27.0	42.2	42.0	28 6

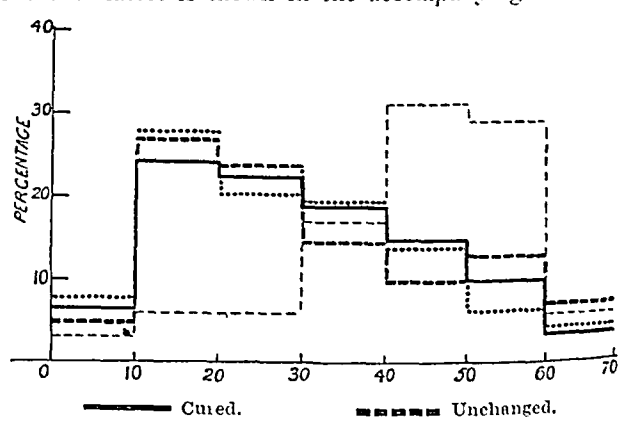
Vaccines	73.0	69.7	57.2	61 0



* Temporary.

The figures shown above are the percentages of all cases "cured," "improved," etc., which showed a positive heredity or were treated by drugs and so forth.

series, which is 21.6 per cent. in each case. Cases of longer than five years' duration naturally show a smaller proportion of "cures." The same point is illustrated also by the average duration of the illness in each group—the figure for the "cured" being 7.3 years, in contrast to 10.6 years for each of the "improved" and "unchanged," and 10 years for those who died. These figures indicate the importance of prompt and efficient treatment, and show that the earlier the case is attended to the better the result. The outlook is by no means hopeless, however, in cases of longer duration, for of the ten who had suffered for upwards of thirty years one was returned as cured and five as improved.

Age at Examination.

The ages of patients when first seen ranged from earliest years up to 70. The percentage in each decade for the different classes is shown in the accompanying chart. The

The age of patients when examined at the clinic. The percentage distribution by ten-year periods of the different groups is shown graphically.

numbers for the first ten years are probably unduly low since many of the younger patients are dealt with elsewhere. In the succeeding age periods, the values for the groups other than the dead decline fairly uniformly. The "unchanged" group shows a slight excess between the ages of 20 and 30, and again after 50. The age when the

patient commenced treatment is in itself probably of little importance when allowance is made for the age at first onset of the disease and for the length of time it has been in existence.

Relation to Etiological Factors.

Heredity.—The occurrence of asthma in one or more of the near relatives of the patients has been taken for our purpose as evidence of a positive inheritance. Such an association has been found in 37.3 per cent. of all the cases in the present series. It should be noted that although a definite inheritance is more common in those patients who begin to have symptoms in the first ten years of life (about 1 in every 2 patients), there is a fairly uniform proportion of positives in each succeeding period (1 in 3 patients). From the table it will be seen that the figures for the cured and for the dead are distinctly lower than those for the other groups. If the occurrence of skin lesions among relatives is also included as evidence of an "exudative" heredity, the figures become even more definite. The percentage of positives for the whole series now becomes 41.0 and for the various groups: "cured" 31.7, "improved" 42.2, "unchanged" 48.4, dead 31.5. An attempt has been made to gauge the constitutional element by grouping the patients according to the number of the following factors which they show: asthma heredity, the occurrence of skin lesions among relatives, and the presence of hay fever, skin rashes, or protein sensitiveness in the patient. It is found that those subjects with the greater evidence of allergy begin to have symptoms earlier in life. From this it would appear that asthmatics having a positive heredity are somewhat less amenable to treatment, and that the less favourable results for the first five years of life might be explained by the greater proportion of hereditary cases commencing at this period.

Protein Sensitivity.—From a statistical point of view it is unfortunate that all the subjects have not been exposed to the same set of proteins. Owing to the large number of individual test substances available, it was not at first found possible to employ them all on each patient, and the choice was mainly guided by the history of the case. Later, the plan of testing every subject with a comprehensive series of "grouped" proteins has been adopted. The figures obtained, therefore, do not necessarily represent the true extent of sensitization, but merely the positive reactions found. The "positives" recorded include multiple sensitivity as well as single specific responses. The groups give a similar proportion of positive results, except that the figure for fatal cases is a little low. It should be observed, however, that in the case of the "cured" patients about half of the positives reacted to a *single* protein.

Respiratory Catarrhs and Infections.—These appear to be of great importance in the development of the asthmatic condition at all ages. It is sometimes said that in early life the exudative diathesis manifests itself by respiratory symptoms indistinguishable from bronchitis. After middle life a history of prolonged or severe bronchitis is more commonly found as a forerunner of the asthma. The patients, when examined, were merely asked whether such conditions were present at the time of, or immediately before, the first attack of asthma, and no account has been taken of previous health in regard to respiratory disorders. The proportion of individuals who give this history is high, and is much the same in each group. There is really no significant difference between the groups in this respect, and this factor does not appear to influence the result of treatment.

The Fatal Cases.

This group stands out from the others in various respects. Inheritance and protein sensitization are rather lower in this class, while respiratory infections are much the same as in the others. The average age of onset in the group is considerably higher—namely, 34.4 years, as contrasted with 21.5, 17.5, and 20.4 for the others. While 7 cases began before the age of 20, a large percentage of this group developed symptoms after middle life. A number of deaths is to be expected in such a group, but the proportion actually recorded is very much greater than would occur in a similar age sample of the community during the same length of time. Of the 36 deaths, 28 occurred in subjects over the age of 40, 3 were under 20 years of age, and 5 between 20 and 40. Acute illnesses accounted for at least 8 of the deaths; these were influenza (patients aged 7, 14, 48, 55); pneumonia (aged 17); cholecystitis (54); meningitis (40); gastric haemorrhage (39). There were two suicides (50 and 61). Two fatalities were due to phthisis (26 and 32), both patients having previously had undoubted asthmatic symptoms. Syphilis accounted for 4 deaths (36, 60, 60, and 70) and cerebral haemorrhage for one (51). Five were attributed to heart failure (36, 43, 58, 63, and 70). In the case of the remaining 14 the exact cause of death has not been ascertained. These include some of the most severe cases, in which the patients are known to have been almost constantly dyspnoeic and in a condition of status asthmaticus with advanced emphysema and cardiac embarrassment. Additional information shows that before death 2 of the patients had been "cured" of their asthma, 7 were considerably improved, 2 slightly benefited, and 15 were unchanged. These figures have not been incorporated in the other sections.

Summary.

The results of treatment in 291 cases of asthma are reported. Of these, 66 per cent. have been benefited and 12.4 per cent. have died. No single scheme of treatment can be laid down for all cases; each patient must be treated individually. The most successful forms of therapy appear to be elimination when applicable, and vaccine treatment where respiratory infections complicate the asthma. Cases which react to a single protein are usually favourable, but the occurrence of multiple sensitivity is of little importance in relation to treatment. Among many factors less easy to assess, change of residence and general hygienic measures have contributed to the patients' improvement. The results of operations on the nose or throat are disappointing, and such treatment should only be recommended to relieve definite local symptoms. Cases arising in the first five years of life are less successful than those beginning later. This may depend on the unfavourable factor of a positive heredity. Asthmatic symptoms commencing after middle life are also apt to be less amenable to treatment. The duration of the disease before effective treatment is undertaken is of the greatest importance; the longer the delay the less satisfactory the result, although certain cases of long standing have benefited considerably under adequate treatment.

A GOITRE SURVEY IN ALBINO RATS.

BY

ROBERT McCARRISON, C.I.E., K.H.P., M.D., F.R.C.P.,

COLONEL, INDIAN MEDICAL SERVICE: DIRECTOR, NUTRITIONAL RESEARCH, I.R.F.A., PASTEUR INSTITUTE, COONOOR, S. INDIA.

DURING the past three years the practice has been followed of recording, at post-mortem examination, the state of the thyroid gland in all animals used in the laboratories of the Pasteur Institute, Coonoor, for experimental work on diseases of faulty nutrition. Post-mortem records of 2,561 albino rats have accumulated during this period. It is with these that the present survey deals.

Of the 2,561 animals 393 were "controls" fed throughout life on complete diets, and 2,168 were rats fed from an early age (approximately 40 days) until the time of their death on various deficient diets. Goitre did not occur in the former group; 148 cases of the disease occurred in the latter. The goitres were classified as follows: (*a*) Small enlargements amounting to less than twice the size of the normal organ, 84; these were called "slight goitres." (*b*) Moderate enlargements amounting to more than twice but less than four times the size of the normal organ, 41; these were called "small goitres." (*c*) Marked enlargements amounting to four or more times the size of the normal organ, 23; these were called "large goitres."

The relation of these goitres to endemic and hereditary influences, to hygienic conditions of life, to age, sex, and atmospheric temperature, to food, and to iodine, has now to be considered.

Endemic Influences.

Goitre is not endemic in Coonoor, nor in its neighbourhood. The indigenous inhabitants are entirely free from it. European and Anglo-Indian settlers do not acquire it, though their children may occasionally exhibit slight swellings of the gland, especially girls about the age of puberty. The iodine content of the soil is relatively high—118 to 400 parts per 10 millions (Newcomb). The urinary excretion of iodine by young adult males ranges from 60 to 400γ* per litre. The water supply is piped; it is bacteriologically pure and exceptionally soft. There is a poverty of lime in the soil. Endemic influences played no part in the causation of the goitres with which this survey deals.

Hereditary Influences.

Although many post-mortem examinations have been made in our well-cared-for and well-fed rats, no case of goitre has so far been found among them. This stock has been bred through many generations during the past eight years and has become acclimatized to the altitude (6,000 feet above sea-level). New blood is introduced from time to time to prevent in-breeding. The rats are small-sized and their thyroids are, at all ages and body weights, about half the size of those of albino rats used for experimental work in the United States of America (Fig. 1). Hereditary predisposition—a potent influence in the genesis of goitre—played no part in the causation of the goitres with which this survey deals.

Hygienic Conditions.

These are as nearly perfect as is possible in animals kept in captivity. A stock of between 500 and 800 animals is maintained throughout the year for breeding purposes. They live in straw-filled, screened cages; a pair with their young to each cage. The cages are kept scrupulously clean, and the straw is constantly renewed. The animals are exposed to sunlight when weather conditions permit, these conditions are favourable for the greater part of the year. The stock diet consists of unleavened bread (chapattis) made from whole wheat flour (atta) and lightly smeared with butter, the hard crusts of white loaves, diluted milk, sprouted "gram" (legume), green vegetables, and carrots *ad libitum*, an occasional small ration of raw meat, and fresh water in abundance. Under these conditions the stock animals remain in perfect health, are very fertile, and invariably rear the whole of their young, no matter how large the litters may be. There is practically no infantile mortality. During the past fifteen months there has been no death from natural causes among this stock. Reduction of their numbers is effected by killing off the older animals when they are 20 to 24 months old; in such of these as have been examined goitre has not been found. The young are removed for experimental purposes when they are about 40 to 50 days old; a sufficient number being retained for replenishment of the breeding stock. From time to time numbers of these young rats have been killed and their thyroids examined; no enlargement of the gland has ever been found. It may therefore be assumed that no young rats come to the experimentation rooms with enlarged thyroids. Any enlargement of the gland occurs subsequent to their transfer from stock.

The young rats used for the experimental production of diseases of faulty nutrition live under similar conditions of perfect cleanliness. Their screened cages are frequently sterilized; droppings adhering to the screens are removed by hand. A large staff of animal attendants is employed to maintain the high standard of cleanliness demanded. The animals are usually confined in separate cages; but sometimes they are paired for special purposes, as when it is desired to note the effects of certain diets on fertility. Their conditions of life differ from those of the stock animals in the following particulars: the majority are isolated from companionship with their kind; they are not provided with straw for bedding; and their food, except in well-fed controls, is invariably faulty in some respect. Both in the stock rats and in those used for experimental purposes the goitrigenous influence of "dirt"—a potent one in ill-fed animals—is thus rigidly excluded. This factor was not, therefore, concerned in the causation of the goitres with which this survey deals.

* γ represents 1/1,000 of a milligram.

Influence of Sex.

Among the 148 goitres there were 56 in males and 92 in females—an incidence of 4.5 per cent. in the former and of 7.8 per cent. in the latter. This difference in sex incidence is in conformity with the well-known fact that females are more subject to goitre than males.

Influence of Age.

One fact of probable significance emerged from a statistical analysis of the data relating to the age of the animals and the incidence of goitre. The incidence of the disease was highest (12.4 per cent.) in rats whose age—100 to 120 days—corresponded to the period of attainment to sexual maturity. A second rise, to 11 per cent., occurred in rats aged 220 to 240 days; but the number of animals of this age was small (76). No goitre occurred in rats aged 60 to 80 days. At age periods other than the three mentioned, the incidence of the disease was between 5 and 7 per cent.

Influence of Atmospheric Temperature.

The maximum shade temperature in Coonoor rarely rises above 76° F.; the minimum rarely falls below 50° F. From the middle of March to the beginning of October the maximum temperature in my animal houses is round about 75° F., the minimum round about 65° F. From October to March the maximum is 60° to 65° F.; and the minimum 55° to 60° F., falling occasionally to 50° F., and very occasionally to below 50° F. The temperature conditions prevailing between March and October appeared to be more favourable to the development of these goitres than those prevailing between November and the end of February.

Influence of Associated Diseases.

Associated diseases do not appear to have exercised any influence on the incidence of goitre in these rats: for whatever these diseases may have been—and they covered a wide range of morbidity—they were found as frequently in non-goitrous as in goitrous animals. In 51 of the 148 cases of goitre there was no associated disease.

Influence of Food.

As previously stated, no case of goitre occurred among 393 well-fed rats, while 148 cases occurred among 2,168 deficiently fed rats. This difference is statistically significant. It indicates that faulty food, deficient in certain elements and complexes necessary for normal nutrition, was the direct, or the indirect, cause of the goitres from which the rats suffered.

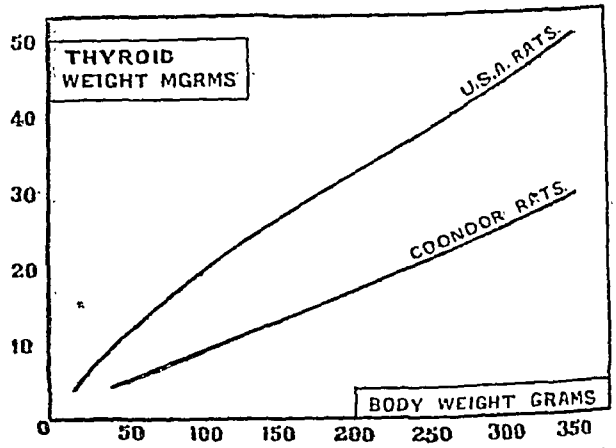

FIG. 1.—Showing the weight of the thyroid gland of Coonoor albino rats according to body weight (regression line $y = 0.080x + 1.24$; standard deviation of thyroid weights about the regression line: 1.35; correlation between thyroid weight and body weight: + 0.95. For these calculations I am indebted to Lieut.-Colonel C. Newcomb, I.M.S.). The curve of thyroid weights for U.S.A. albino rats (Donaldson's *The Rat*, 1924, p. 218) is included for purpose of comparison.

1. *The Well-fed Group.*

Of the 393 animals in the well-fed group 121 were controls, fed on stock diet. They were killed by drowning. Their thyroids were removed and weighed, and the weights charted against the body weights of the animals (Fig. 1).

So far from any of these thyroids being enlarged they were all found to be small relative to those of albino rats in the United States of America.

Forty animals in the well-fed group were fed, from the age of 40 days to the end of their lives, on certain national diets of India. These were of good biological value and of similar composition to that on which the stock rats were fed. The animals were killed by drowning on the 198th day of life; none were goitrous. A third group of 144 were fed on certain complete natural diets into which whole milk entered largely; these also were killed by drowning, at ages ranging from 200 to 220 days; no case of goitre occurred among them. The remaining 88 animals received complete synthetic diets containing iodine in the form of potassium iodide, this salt comprising 0.45 per cent. of the "salt mixture" (McCollum's) used in the preparation of the diets. These were killed by drowning at ages varying from 143 to 254 days; none were goitrous. It is to be noted that in the presence of a complete diet the continued ingestion of iodine in relatively large amounts did not cause thyroid enlargement in any of the 88 animals.

The average urinary excretion of iodine by the animals comprising the well-fed group was as follows: (*a*) stock diet, 56γ per litre; (*b*) national diets, 85γ per litre; (*c*) milk diets, 70γ per litre; (*d*) synthetic diets, 200,000γ per litre.

2. *The Deficiently Fed Group.*

A large number of faulty diets were used in the feeding of the 2,168 animals comprising this group. It is unnecessary for my present purpose to describe each of these in detail. Some were synthetic diets made up of refined materials; but the majority were defective diets composed of foodstuffs in common use by man. All had one or other or several of the following faults: deficiency of vitamin A, deficiency of vitamin B (fractions not differentiated), deficiency of vitamin C, deficiency of mineral salts, and deficiency of animal protein. No diets were used in which "vitamin B" (or either of its fractions), "vitamin D," "mineral salts," or "protein" was the sole deficiency. The various diets were grouped, according to the nature of their defects, into twelve categories. These, together with the number of animals used and the number of goitres occurring among them, are shown in Table I.

TABLE I.—*Showing Deficiencies of Diets, Number of Animals Fed on the Deficient Diets, and Number of Goitres.*

Category	Deficiency or Deficiencies of the Diets.	No. of Animals Used.	No. of Goitres.	Percentage Incidence of Goitre.
I.	Vitamin A	79	2	2.5
II.	Vitamin C	110	0	0
III.	Vitamins A and C	306	17	5.5
IV.	Vitamins B and C	54	1	1.8
V.	Vitamins A, B, and C	357	42	11.4
VI.	Vitamin A and animal protein ...	20	1	5.0
VII.	Vitamins A and B and animal protein	36	4	11.1
VIII.	Vitamins A and C and animal protein	354	11	3.1
IX.	Vitamins A, B, and C and animal protein	30	6	20.0
X.	Vitamins A and C, mineral salts and animal protein	628	55	8.7
XI.	Vitamins A, B, and C, mineral salts, and animal protein	120	7	5.8
XII.	Vitamin C, mineral salts, and animal protein	64	2	3.1
	Total	2,168	143	6.8
	Nil: Complete diets	393	0	0

These results appear to justify the general conclusion that vitamin deficiency was the main dietetic factor concerned in the occurrence of goitre in the rats under survey. While not desiring to assign to any single vitamin deficiency a paramount place in favouring the development of these goitres, it would seem from the foregoing data that deficiency of vitamin A was of great importance, that a combination of vitamin deficiencies was more potent in favouring the development of goitre than the deficiency of a single vitamin, and that default of other food essentials, such as suitable protein and mineral salts, was not without some contributory influence. Whatever may have been the paramount dietetic factor concerned in the production of these goitres the broad general fact remains: rats living under sanitary conditions and fed on perfectly constituted diets did not develop goitre, whereas rats fed on imperfectly constituted diets did.

Some of the deficient diets were of a composition admitting of little or no growth, as, for instance, when their content of certain vitamins was very low; the period of survival of these rats was relatively short. Other diets, though lacking optimum amounts of one or more vitamins, contained enough to allow of considerable growth, and of longer periods of survival. An analysis of the rates of growth and of the periods of survival of the 2,168 ill-fed rats with respect to size of the goitres showed that the greater the daily average gain in body weight and the longer the period of survival, the larger, as a rule, were the goitres. Thus, a diet composed of white flour, meat residue, olive oil, salt mixture (containing potassium iodide), and water permitted of little or no growth in young rats, though a few survived for periods as prolonged as 165 days and were then killed. The incidence of goitre (which was of the lymphadenoid type) in rats fed on this diet was 25 per cent.; but all the goitres were "slight" or "small." On the other hand, a diet composed of white bread, dried yeast, lime, and feebly iodized water admitted of considerable growth and of the survival of some animals for periods as prolonged as 191 days. The incidence of goitre among young rats fed on this diet, during the spring and summer months, was 41.7 per cent., the majority being "large goitres." Both the rate of growth and the period of survival of the animals were dependent in great measure on the character of the food and the degree of its defects. The dietetic conditions most favourable to the production of considerable goitres were provided by diets composed of foodstuffs which, while deficient in certain essentials (chiefly vitamins), were not wholly devoid of them.

The urinary excretion of iodine by animals fed on the deficient diets ranged between 33 and 158γ per litre; except in animals fed on synthetic diets containing potassium iodide, when it averaged 200,000γ per litre.

Influence of Iodine.

Iodine, either in the form of iodized drinking water or of potassium iodide, was added to the diets of 630 of the 2,168 ill-fed rats; it was not added to the diets of the remaining 1,538. Seventy-three cases of goitre, or 11.5 per cent., occurred among those receiving iodine; 75 cases, or 4.8 per cent., occurred among those not receiving iodine.

Of the twelve categories into which the deficient diets fell (Table I) there were three which afforded definite information regarding the effect of adding or withholding iodine. These were: (III) a combination of vitamin A and vitamin C deficiencies, other essentials being adequate; (V) a combination of vitamin A, vitamin B, and vitamin C deficiencies, other essentials being adequate; and (X) a combination of vitamin A and vitamin C deficiencies with deficiency of mineral salts and of animal protein. Grouping the diets having these faults together, it was found that 576 animals fed upon them had iodine added to their food, while 725 had no iodine added to their food. In the former there were 66 goitres, or an incidence of 11.4 per cent.; in the latter there were 48 goitres, or an incidence of 6.6 per cent. Taking into consideration only those experiments in which goitre occurred it was found that there were 73 goitres among 378 animals to whose food iodine was added, and 75 among 1,236 animals to whose food iodine was not added; an incidence of 19.3 per cent. in the former, and of 6 per cent. in the latter.

Twelve of the 23 "large goitres" occurred in 72 animals to whose food iodine was added; an incidence of 16.6 per cent. Eleven of the 23 "large goitres" occurred in 220 animals to whose food iodine was not added; an incidence of 5.9 per cent.

Seventeen of the 41 "small goitres" occurred in 132 animals to whose food iodine was added; an incidence of 12.8 per cent. Twenty-four of the 41 "small goitres" occurred in 500 animals to whose food iodine was not added; an incidence of 4.8 per cent.

Forty-four of the 84 "slight goitres" occurred in 174 animals to whose food iodine was added; an incidence of 25.3 per cent. Forty of the 84 "slight goitres" occurred in 456 animals to whose food iodine was not added; an incidence of 8.7 per cent.

These differences are statistically significant; they indicate that the administration of iodine to the deficiently fed animals definitely favoured goitre-production.

The urinary excretion of iodine in the rats to whose deficient food iodine was added, and amongst whom goitre occurred, ranged between 85 and 158γ per litre, except in animals fed on synthetic diets containing potassium iodide, when it averaged 200,000γ per litre.

Histological Appearances of the Goitres.

Ninety-five of the 148 goitres were serially sectioned and examined microscopically. In 16 of these the post-mortem changes were so marked as to obscure the histological picture. The remaining 79 fell into the following groups, though it was not always easy to decide to which group certain specimens belonged.

(*a*) Nine were glands presenting no abnormality other than their "slight" increase in size.

(*b*) Seven were "slight" or "small" enlargements in which intense hyperaemia was the only obvious pathological change.

(*c*) Eight were colloid glands, all being "slight goitres." Some of them contained small keratinization cysts.

(*d*) Sixteen were simple hypertrophic enlargements, several appearing to merge into the lymphadenoid condition. Nine were "large" and seven were "small" goitres.

(*e*) Thirty-five were lymphadenoid goitres, 25 being "slight," 4 "small," and 6 "large." The characters of this type of goitre and the dietetic conditions under which it arises have previously been described in this *Journal*.

(*f*) Four were chronic hypertrophic goitres, presenting the features characteristic of this condition. All were of moderate size and all occurred in rats fed for long periods on natural diets consisting largely of whole wheat flour (atta) but poor in green vegetables and in vitamin A-bearing ingredients.

Summary.

1. A survey was made of 2,651 albino rats in a locality (Coonoor) where goitre is not endemic; 148 were found at post-mortem examination to have goitre. Of these goitres 84 were classified as "slight," 41 as "small," and 23 as "large."

2. The temperature conditions of the spring and summer months in Coonoor appeared to have been more favourable to the development of the goitres than those of the autumn and winter months.

3. The incidence of goitre was higher in females than in males.

4. Goitre was commonest in rats whose age corresponded to the period of attainment to sexual maturity.

5. Associated diseases did not appear to have exercised any appreciable influence on the incidence of goitre in these rats.

6. The goitres are not due to endemic influences.

7. The rats had no hereditary predisposition to goitre, nor were they subjected to insanitary conditions of life; both of these influences are favourable to the genesis of goitre.

8. Well-fed rats (393), living under sanitary conditions, did not develop goitre; ill-fed rats (2,168), living under sanitary conditions, did. The incidence of goitre in the latter was 6.8 per cent.

9. Faulty food deficient in vitamins was the direct, or the indirect, cause of the goitres.

10. The dietetic conditions most favourable to the production of considerable goitres were provided by diets deficient in, but not wholly devoid of, certain food essentials (chiefly vitamins).

11. The administration of iodine to deficiently fed rats was definitely favourable to goitre production; its administration to rats fed on physiologically complete diets did not favour the occurrence of goitre.

12. All grades of goitre ("slight," "small," and "large") were more common in deficiently fed rats to whose food iodine was added than in those to whose food iodine was not added.

13. The urinary excretion of iodine by rats fed on deficient diets having a composition favourable to goitre production was in some experiments as low as 33γ per litre and in others as high as 200,000γ per litre.

14. The histological appearances of 79 of the 148 goitres are briefly described; 44.3 per cent. were lymphadenoid goitres; 25.3 per cent. were hypertrophic goitres, some merging into the lymphadenoid condition.

15. The normal thyroid glands of Coonoor stock albino rats are, at all ages and body weights, approximately half the size of the normal thyroid glands of albino rats in the United States of America. Standards of normal thyroid weights for albino rats in one part of the world may not be applicable to albino rats in another part of the world.

COKE-MEN AND BY-PRODUCTS WORKERS: THEIR COMPLAINTS AND MALADIES.

BY

SIR THOMAS OLIVER, M.D., F.R.C.P.,

EMERITUS PROFESSOR OF MEDICINE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

COKE, so essential for the smelting of iron, and also useful for domestic heating, is the residue left when coal has been subjected to a high temperature, away from contact with air, and which during the process of carbonization has lost several of its volatile constituents. It is a British product. Coking of coal goes back as far as 1590, when a patent was granted to John Thornborough, a Dean of York. Until recently, the carbonization was mainly effected in what are known as "bee-hive" coke ovens, rows of which can be seen from almost any railway train passing through a mining area. When these ovens are properly filled with coal, closed up, and heated by flues, the gas given off ignites within the ovens and fills the dome with flame. When all the gas has burned off the upper part of the dome is opened, the red-hot material inside is cooled by water spray, and is subsequently removed. As this is a wasteful method, "bee-hive" ovens have been replaced by "retort" and by "by-product" ovens. In the latter the gases are not burned off at their point of origin inside the oven, but pass by an up-take pipe to the roof into a water-sealed trough or collecting main, whence, to quote from the *Encyclopaedia Britannica*, "they are drawn by exhausters through a series of air and water-cooled condensers and scrubbers." In the first condenser, tar is deposited by the fumes passing from the ovens, and in the second the ammoniacal liquor is caught. This liquor, after a process of scrubbing, and with its ammonia content increased, passes on to the ammonia stills. During scrubbing with creosote or heavy tar oil, benzene is removed. When the remaining material is distilled, the tar, having yielded up burning oil, becomes pitch, and the benzene is removed from the creosote oil by steam in heated stills. To the ammoniacal liquor lime is added, and on heating this the ammonia is vaporized. The ammonia is collected, and is subsequently condensed in metallic tanks containing sulphuric acid. Ammonium sulphate—a highly valued product for manurial purposes—is thus formed. Further by-products can still be obtained, such as toluol, naphthalene, pyridine, and motor spirit—the last, also known as benzol, being a mixture of benzene, toluene, and xylene.

The by-products obtained from coal vary with the coal-fields which furnish the raw material. South Wales coal gives the largest amount of coke—80 per cent., compared with 75 per cent. from that of county Durham; but Durham coal furnishes a larger amount of tar—3.85 per cent., compared with 2.6 per cent. from Welsh coal. The coal of South Yorkshire contains the largest amount of crude benzol—namely, 1.37 per cent.—while the coal of Durham contains 0.93 per cent., and that of South Wales 0.60 per cent. These figures are interesting, not on account of their varying commercial and economic values, but because they

probably explain some of the differences observed in the complaints and maladies of the workers.

In a works plant those who suffer most severely are the men working at the hydraulic mains which carry the heavy, thick fumes directly away from the ovens. Lids on the mains have to be opened, and the sluggishly moving tar is pushed on with long iron implements so that it does not block the channel. During this brief operation it is impossible for the men to avoid inhaling some of the dense fume that rises into the air, and their bare skin cannot be otherwise than adversely affected by the contact. The men whose duty it is to close the valves at the entrance of the hydraulic mains proximal to the ovens, to prevent any reflux from the hydraulic mains towards the ovens, are affected in a similar manner by the escape of fume. Precautionary measures have to be observed at every stage, for even at the terminal stages there are risks to health and limb. This is true in the distillation of tar. A leakage may occur owing to a structural defect in a still, and burns may be caused if the tar ignites. The stills have to be periodically cleaned out, and the residue, which adheres firmly to the interior, has to be removed with a pick; this is a dusty proceeding.

In England and Wales 15,000 men are employed at coke ovens and in by-products works. Although there is a National Union of Coke-men and By-products Workers, it is difficult to obtain exact data of their illnesses, as they are members of different benefit societies. For several years workers in this industry have been supposed to suffer from stomach troubles to a greater extent than those following other vocations; this is indeed their most frequent and disabling complaint. There are other maladies to which they are also especially susceptible—for example, rheumatism and lumbago, skin eruptions, and warts, the latter being frequently the forerunner of ulcers which assume the characters of malignancy. Medical men residing in mining areas who attend the indisposed workmen call the stomach trouble gastritis, but there has not been, so far as I am aware, any pathological report based upon post-mortem examination clearly defining this condition, apart from cases in which cancer was found after death in the mucous membrane of the stomach of patients who were said to have had gastritis. The frequency of gastric complaints is widely admitted, particularly in the county of Durham. Symptoms develop at any age and at any period of service, in some instances three or four years after commencing work; in one patient whom I saw only six months had elapsed; the majority of the cases occur during the second or third decade of work. The symptoms complained of are pain in the region of the stomach one or two hours after taking food (although on other occasions the pain may have no relation to food), attended by flatulence, belching of sour gas, and the expulsion of acrid liquid or what is known as "water-brash." Sometimes the pain is so severe that even strong men are overcome by it. There may be marked distaste for food; on the other hand, appetite may not be impaired. The mere sight of food may cause a feeling of sickness, which ends in the vomiting of sour liquid. With the exception of a little milk no food is taken for a day or two. There are periods of remission during which the men return to work, and continue working for years with occasional digestive breakdowns. Some of them on reaching home after a day's work are drowsy, and fall asleep before taking a meal. They have a sense of fatigue which muscular work does not explain; it is toxaemic. In a considerable number who present these gastric symptoms ulceration of the lining membrane of the stomach ensues, while in a smaller number the malady ends in cancer. Surgical treatment may become necessary when the symptoms of ulceration are severe, or where the ulcer has perforated the wall of the stomach. Recovery is possible, but an operation sometimes reveals not a simple ulcer, but a malignant growth. Sallow complexions are common. It is exceptional to find workmen who have spent fifteen or twenty years in the industry with the ruddy glow of health. They usually lose their colour in time. I have been struck by the light weight of many of the men. Some of them weigh only 8 st.; they readily inform the medical examiner of the weight they have lost. The work is admittedly not heavy, but it is fatiguing owing to exposure to great heat and fume.

Men employed in by-products works are liable to rashes on the skin, to warts, which, as already stated, become epitheliomata, a form of cancerous growth with ulceration, also to burns; especially is this the case among workers in tar. The rashes appear mostly on the skin of the back of the hands and forearms, usually commencing as an acute inflammation of the skin or dermatitis; the redness is accompanied by a considerable degree of itching, and by the presence of small circumscribed elevations of the skin called papules, which may become pustular and painful. Boils form, and these, when they have discharged their contents, leave a bluish flat mark. Warts are not uncommon; their presence is hazardous, for they are apt to be irritated or rubbed off and to become malignant. They appear on the back of the hands and forearms, also upon the scrotum and penis; so long as they remain simple warts they can be successfully removed, but when they become malignant the genitalia and infected glands in the groin may have to be removed. If the malady has progressed too far surgical treatment can give only temporary relief; yet a considerable length of life may be assured, for some of the patients I have examined had been operated upon seven or eight years previously. The warts appear in various situations. I have alluded to their presence on the genitalia. I have seen them on the brow, on the eyelids, also hanging from just inside the nostrils. They have the usual rough, uneven surface of warts generally, and they are dry and painless. The skin of the hands, which is often freckled, is hard, thickened, and disposed to crack. The "keens" thus formed are painful, and do not heal readily if work is continued. Small shot-like bodies are occasionally felt in the skin of the arms; these are not painful at first: the superjacent skin subsequently becomes red, then dark, then it fades away, and a white mark is left. Small, red, angry-looking spots frequently appear on the chest, accompanied by itching, or there may be large, black, warty moles, especially on the back of the trunk.

During the breaking up of solid pitch no fine dust may be observed in the atmosphere a few feet above the surface of the pitch, but if the men do not wear goggles they frequently suffer from an acutely painful inflammation of the eyelids, the result either of fume or of a very fine impalpable dust. The skin of the hands and of the other parts of the body becomes reddened and itchy. These symptoms are commoner among the men who break up the pitch obtained from Durham coal than among those similarly employed in Derbyshire, which suggests that there is some inherent difference in the coal. Many tar and pitch burns become septic.

As might be expected from exposure to heat and cold, the men suffer from bronchial and other types of catarrh, and from rheumatism and lumbago. Recurrences of bronchial catarrh predispose the individual to pulmonary tuberculosis, or to a general breakdown in health in the early forties, followed by physical unfitness to resume work at the coke-ovens. I have not been able to confirm the possibility that workers are poisoned by sulphuretted hydrogen, although an equally subtle form of poisoning may occur at the level of the ovens. The doors of the ovens have to be sealed as hermetically as possible. Now and then, either as a result of the expansion of the raw material during its conversion into coke, or of the displacement of a brick, there is a leakage of gas at the sides and at the foot of the doors of the ovens. Not long ago a workman employed at the ovens was suddenly observed to fall and to become unconscious; he was removed; a similar fate befell his successor. A leak had occurred, probably of carbon monoxide gas. The leak was sealed up, but two days later when the coking operations had been resumed, a fresh workman was similarly overcome by gas at the same oven door.

I have recently examined twenty-three by-products workers who were under medical treatment, thirteen of these for gastritis and six for boils. It would be unreasonable to take these figures as in any way indicating the percentage of men in this industry who suffer from stomach trouble, because the men who were examined were more or less picked. At the same time I have received the

impression from conversation with doctors in the mining areas that frequency of painful digestion and inability to take food are general symptoms.

With reference to occupational, scrotal, and penile cancer I have had the records of the Royal Victoria Infirmary, Newcastle-upon-Tyne, examined for the last two years, and I find that in 1928 fourteen operations concerned with these types of malignant disease were performed; three of the patients were coal miners, two were gas stokers and chemical workers. Five were men aged 50 to 60, three 60 to 70, and three 70 to 80. During 1929 sixteen patients were operated on for the same malady; of these eight were coal miners, one a worker in oils, and one in pitch; four were aged 50 to 60, five 60 to 70, and five 70 to 80.

Smoke, fume, and excessive heat with alternating exposure to cold are the harmful agents. In such an inquiry as I have been making two forms of illness have to be considered: there are the minor forms which cause a good deal of discomfort and temporary disablement, and which may be regarded as complaints of the workmen—for example, loss of appetite, pain after food, and vomiting, the lighter forms of skin troubles such as itchiness, boils, and "keens" on the hands; and there are the more serious forms of illness which result in cancer. The occupational operations we have been dealing with concern the manufacture of products obtained from the combustion of coal. There is a difference in regard to the manipulation of the raw material and the products obtained from it. The products obtained from coal are the more harmful. Chimney-sweeps, for example, have for long exhibited a high liability to scrotal cancer; so, too, have briquette makers, workers in mineral oils, arsenic grinders, colour mixers, and workers in tar and its derivatives. With "pitch cancer" we have long been familiar.

In Germany tar distillation is the cause of a higher percentage of accidents than any of the other operations. Pitch breakers there suffer considerably, too, from eczema, but cases of cancer are comparatively few. In Upper Silesia, however, of thirty anthracene workers who had been employed for over ten years twenty-two suffered from skin eruptions, and three, with six to eight years' service, had been operated on for scrotal cancer. In France coke-men and tar workers suffer from dermatitis, but cancer is less frequently met with than in Great Britain. Cancer is infrequently observed in the United States. Dr. Thacher of the Chicago By-products Coke Corporation informs me that the ailments of the men in his employment are the same as those of the men following other trades in the district—namely, severe colds and influenza; he also states that a few of the men suffer from gastric ailments. Heart disease is a common cause of death, but, in his opinion, he does not regard this circumstance as in any way related to their occupation. During the last three years one workman died from cancer of the stomach.

Twenty years ago Sir Thomas Legge drew attention to the fact that blast furnace tar and pitch do not possess the same carcinogenic properties as those of coal tar. The pitch obtained from coke ovens and gas works and used for making briquettes is said to be the cause in Great Britain of more than one-half of the notifiable cases of cancer. Drs. Bridge and Henry, in an investigation between 1920 and 1927, found that of 163 cases of cancer occurring among briquette workers, in 11 per cent. the disease was located in the scrotum, and in 71.2 per cent. in the head, arms, etc.; that out of 103 cases among tar distillers 39.8 per cent. were affected in the scrotum and 37 per cent. in the head, limbs, etc.; while in 47.3 per cent. of the men employed in gas works the disease was located in the scrotum, and in 23.6 per cent. in the head and elsewhere. Interesting information is also supplied by Dr. Prosser White in his encyclopaedic work *Occupational Diseases of the Skin*, by Dr. O'Donovan, and by Dr. Scott of Broxburn in his helpful monograph upon the incidence of cancer among workers in shale oils and their derivatives.

A microscopic examination of the blood does not reveal anything absolutely definitive. This may be due to the fact that the work is carried on in the open air, and is to some extent interchangeable. In some cases the blood shows a marked deficiency of leucocytes or white corpuscles; in others the number of these cells is practically normal.

Although the atmosphere of by-product coke ovens and the conduits which carry the liquid and gaseous material away from them is redolent of fume, there are, as already stated, certain classes of workers engaged in the transit of the material whose health appears to be more severely affected than others in the industry, such as workers at the top ovens, at the hydraulic mains, the men who adjust the valves in the shafts leading into the hydraulic mains, and those who break up the solid pitch—all these are liable to be adversely affected by dust, heat, and fume.

While the main incidents of the industry from a health point of view are painful and irritating conditions of the skin, some of which exhibit a tendency to become malignant, there are also the stomach troubles to which reference has been made; of these it may be said that the severity of the pain experienced by the workman, the physical debility that ensues, and the consequent loss of time, together form a triad of circumstances which call for recognition and careful consideration dietetically, medicinally, and industrially.

BATHS AS ARTIFICIAL CLIMATES.

THE TREATMENT OF RHEUMATISM IN WINTER.*

BY

R. FORTESCUE FOX, M.D., F.R.C.P.,

PRESIDENT, LA LIGUE INTERNATIONALE CONTRE LE RHUMATISME; CHAIRMAN, BRITISH COMMITTEE ON RHEUMATISM (I.S.M.H.), 1925–29.

SINCE the attention of the medical profession has been directed to the chronic rheumatic diseases two lines of advance have been energetically followed, especially in England and America—namely, the investigation and treatment of the infective element in these diseases, and the use of orthopaedic methods for the rectification of posture, avoidance of pressure upon inflamed joints, and prevention and cure of deformity. Good work on these lines has brought relief in many intractable cases, and is a welcome contribution to the campaign against rheumatism.

It is, however, possible to approach this problem from another and equally logical point of view. Five years ago an international committee on rheumatism, consisting of a small group of medical men who had long experience of rheumatic diseases in the northern countries of Europe, came into existence. They held conferences in France, Holland, Germany, Czechoslovakia, Hungary, Austria, and England.[1] The committee, now an international league, has become a small connecting link between larger national bodies in these countries as well as in Russia and America. Many of their members are specializing entirely in this group of diseases; some are workers at university clinics, physicians or directors of hospital departments, of special hospitals for rheumatism, or of bath clinics in towns; others are engaged in the treatment of rheumatism on a large scale in spas and health resorts. It is clear from the various reports on rheumatism issued by the Ministries of Health and Social Welfare, especially in England, that this large group of diseases has a vast incidence in cold climates, and that it is chiefly responsible for crippling and disablement in great industrial populations, not tending to shorten life, but spreading like a blight over the working period of life. The problem, apart from its medical interest, is also of great economic importance.

In the view of the league such a mass of invalidity in the best years of life demands an organized and co-operative effort for special investigation and special methods of treatment. Existing provision of this kind, especially for the treatment of early cases, is at present so fragmentary that only an insignificant fraction of the vast number of rheumatic persons can benefit by it.

The league attaches great importance to the investigation of causation. Its provisional statement[2] comprises four prime factors: a cosmic or external influence—

*An address (abridged for publication) given to the Tunbridge Wells Division of the British Medical Association, March 19th, 1930

climate, surroundings, and occupation; a constitutional anomaly which causes some to suffer while others escape; a defective function of the skin; and a factor of infection. These factors operate so variably and unequally that sometimes one and sometimes another appear to be dominant, with the result that diagnosis and treatment become an individual study.

What are the conditions that make infection operative?[1] To obtain a true picture of the etiological field all such conditions, whether essential or accidental, must be elucidated. The merulius is not a sufficient cause for dry rot in timber: there must also be a deficiency of oxygen and heat. I confess to an inveterate belief that one of the essential conditions in the production of rheumatic diseases is the influence of cold and damp. In a biological sense climate signifies the energies outside ourselves, from which are drawn the stimuli necessary to life. The healthy organism reacts to them favourably; but if from any cause it has lost physiological contact, if a warm-blooded animal fails in its normal reactions to the stimulus of cold in a medium many degrees cooler than itself—if, that is to say, external cold no longer generates internal heat—then another series of less favourable reactions will occur. The demand made upon physiological heat production is very variable, both in the same locality and in different localities. The maximum demand is made in northern climates, especially in winter and spring, and the minimum demand in equatorial regions at all seasons of the year.

In the young and healthy the impressions of cold appear to evoke a perfect response and adaptation. The whole sensitive keyboard can be safely played upon; but in age and disease the limits of safety may be confined to a few notes. The activity of the heat-generating muscular system is an important element; with active locomotor organs it is possible to make good any loss of heat by muscular exercise. That is impossible for rheumatic persons who are deprived of their activity. There is one law for the fit and another for the frail, and the exposure which brings vigour to the one is dangerous to the other. It follows that for each person there is an ideal external temperature which best promotes the harmonious working of the functions, and an ideal range of temperature within which their reactions may be exercised.

The well-known results of severe exposure of healthy subjects, or slight exposure of sensitive subjects, may be summarized as follows:

(*a*) *Low Temperature of the Skin.*—In health, with an air temperature of 10° C. (50° F.), the uncovered parts of the skin are from 3° to 4° C. cooler than the covered part.[1] Upon undressing in a cold room the skin cools down, the loss of body heat increasing by at least a third. A marked lowering of skin heat is therefore an immediate result of exposure, and becomes a protection against further loss of heat.

(*b*) *Contracted Peripheral Circulation.*—The capillary bed is more or less closed with areas of complete stasis, which is a chronic condition in sensitive subjects under repeated exposure.

(*c*) *Inactivity of the Sweat Glands.*—It is a cardinal fact that transpiration, or true sweating, is in abeyance in cold climates, and can only be produced artificially by strong exercise or external heat.

(*d*) *Lowering of the Temperature of the Body.*—In proportion as the response to cold by production of heat fails, oxidation and metabolism are defective, and the exposed body loses heat like an inanimate object.

(*e*) *Lowering of Resistance to Additional Exposure, and especially to Infection and Injury.*—Lode[2] has shown that rats with a temperature artificially lowered by 4° to 5° C. are extremely vulnerable to infection, 85 per cent. dying of inoculated staphylococcus, pneumococcus, or tubercle, as against 12 per cent. of normal animals. Pasteur's classical experiment may be recalled, showing that poultry after standing in cold water easily fall victims to chicken cholera. It seems clear that repeated or prolonged chilling causes alterations in the tissues, with diminished power of forming antitoxins.

The effects of heat in baths are exactly the contrary. (*a*) Baths raise the temperature of the skin, so that the skin becomes not the coolest, but the hottest part of the body; (*b*) they increase the circulation by opening up the capillary bed (the plethysmograph shows increased bulk of a limb immersed in a hot whirlpool); (*c*) they powerfully increase the activity of the sweat glands, which may have been in abeyance for years; (*d*) they temporarily raise the temperature of the blood, and, if it is subnormal, repeated baths may raise it permanently; (*e*) they increase the resistance to cold and injury, and in all probability to infection also.

We may now ask, What are the observed functional disturbances in the early stages of chronic rheumatic disease? It is a striking fact that they are precisely, one after another, the observed effects of exposure to cold in frigo-sensitive persons.[4]

The following table shows the surface temperatures in a woman, aged 37, with arthritis following sea-bathing.[3]

Surface Temperatures in Arthritis.

	Before Treatment.	After Treatment.	Normal (Di Gaspero).[3]
Dorsum of left foot ..	25° C.	31.4°	32.4° C.
Dorsum of right foot	Colder (off the scale)	31.3°	
Left knee	25.8°	—	35.1°
Right knee	25.0°		
Dorsum of left hand	30°	31.3°	32.5°
Dorsum of right hand ...	30.3°	31.6°	

A habitual inactivity of the skin, with contracted peripheral vessels, is an observation familiar enough to students of rheumatism. Schulhof[5] has described the partial closure of the superficial capillary beds. The lowering of resistance to cold and injury are admitted, and it would be difficult to believe that the same is not true of resistance to infection. It would seem, therefore, that there is a group of functional disturbances, making up a clinical entity, which is caused by exposure to climate and is cured by heat in baths, and that these disturbances accompany the development of rheumatic disease. They may, in fact, be regarded as the departures from physiological health to which warm-blooded animals are liable in a cold climate.

What may be described as "chronic chill" is a fruitful field for investigation, at present but little explored. The act of "catching cold" is constantly done, and happily by homely remedies is easily undone, but what is its significance as a cause of disease? Shade,[10] who studied the effects of chill in a German division during a severe winter, records how 2,700 men were exposed to an exceptional degree of cold and damp. Although they were men of three years' field service, "chill diseases" were increased fourfold. He concludes that damp cold brought on rheumatic diseases, and dry cold and wind respiratory troubles.

I suggest that there are large numbers of chilled or chilly persons going about their ordinary avocations with inactive skin, showing areas often 5° or 6° C. below normal, with a body temperature usually subnormal, and with contracted peripheral circulation. They are not yet ill, but they show an exaggerated liability to disease. I agree with van Breemen[7] that the organism often goes on resisting up to a point, until suddenly a barrier seems to be broken down, and rheumatism, perhaps progressive arthritis, sets in, which can hardly be checked.

It is well known that a change of climate is sometimes a cure for rheumatism;[11] as a prophylactic it is much more powerful. For those who need and cannot get it, the elements of a tropical climate might well be artificially produced. I would suggest that baths operate as an "artificial climate," and should be used deliberately as such. This conception is strengthened by an appeal to the long-established habits of northern nations. In bleak and exposed climates the inhabitants have from time immemorial used a people's bath. Its essential feature is always hot vapour, with vigorous stimulation of the skin. The Russians, Finns, Swedes, North American Indians, Eskimos, and also, it seems, the Celtic races in pre-Roman Britain, all used more or less primitive vapour baths, in

which the body was exposed to an intense degree of moist heat. The contemporary practice is equally widespread. The baths of Finland have been well described by Kajava.[12] The circulation, contracted by the cold, is literally whipped into activity in these baths. Another form of artificial climate with vapour at lower temperatures was the Roman bath, which was originally taken from the East and became a part of the Roman civilization in Britain and Gaul. The eastern Hammams have always utilized vapour with surface stimulation and passive movement, but in the so-called "Turkish" bath, introduced into Britain in 1856, only dry heat is used.

In the northern people's baths, ancient and modern, the essential elements are: heat, moisture, surface stimulation by switching and friction, and time. It is idle, perhaps, to speculate whether the disuse in England of sweating baths may be partly responsible for the prevalence of rheumatism and catarrh. But I would submit that heat and moisture, so employed, can, like a hot or tropical climate, rectify the disturbances caused by exposure to cold; that in rheumatic affections, by increasing the circulation, they can prevent the localization of the disease in the joints, disperse swellings already formed, relieve pain, restore the power of movement, and improve if not re-establish the resistance to cold; that, in short, the "bath complex" (heat, moisture, and movement) is, in skilful hands, an exceedingly powerful remedy, perhaps the most powerful, in the prevention and treatment of rheumatic diseases.

Certain indispensable conditions of success remain to be noticed. The question is asked whether the hot bath can produce permanent results. Slow diseases need slow remedies, and chronic rheumatism especially requires a slow, repetitive, and cumulative treatment. In prescribing an artificial climate a little advance should be made from day to day. It is necessary that the bath should be repeated before the surface and deep temperatures and circulation have lost the effect of the preceding treatment. In other words, the climatic influence is, so far as possible, continuous, and the effect gradual and cumulative, as in nature. The poor success of baths in a cold climate is often due, in my belief, to the mistaken doctrine that rheumatic patients require "hardening" or "toning up." It is impossible to counteract chronic disorders of temperature and circulation if after a brief exposure to heat a rheumatic subject is allowed to pass into a cold dressing-room or the open air. To produce results analogous to those of a hot climate the active agency of the bath must be supplemented by a thermal environment[13] in which the patient remains for a few hours each day. All risk of intercurrent chilling must be carefully avoided. Two cases of my own (among many) may illustrate this point.

A middle-aged lady with Parkinson's disease and rigid and painful muscles was recommended to a British spa for long-continued hot pool baths. In the pool, so long as the shoulders were covered, she was free from pain and moved with comparative ease, but exposure to the air even in the pool room, and later in the dressing room, immediately brought back her pain and stiffness. She returned no better for her treatment.

Another chilly subject, a farmer, with severe subacute arthritis of middle life in hands and knees, went south to an Italian spa for hot mud baths. In these baths the pain and stiffness were very soon alleviated, and the warmth of the local climate and of the heated hotel prevented any sensation of chill throughout the cure. He came back walking with comfort, the disease arrested, and the process of cure established.

It is something more than a fanciful analogy that in many chronic diseases man reverts a little towards the condition of cold-blooded or hibernating and immobile animals, and it is not unreasonable to suppose that prolonged and gentle and increasing warmth, like that of the spring, is more likely to restore the warm-blooded state and to overcome chronic chill than brief or alternating exposures. But such a conception would, if accepted, involve the application of a different practice to rheumatic illness from that which usually obtains, and which is undoubtedly proper in other forms of illness.

No single kind of bath is a specific for rheumatism, but four methods may be mentioned which are justified by age-long experience and by precise modern investigation.[14]

1. *The hot pool*, with more or less prolonged immersion. Recently, in Transjordania, I have seen the Bedouin resorting in winter to the natural thermal pools, not for brief immersion but very often for the greater part of the day. Their tolerance of heat is extraordinary. A danger with which hydrologists are familiar was brought to mind at another pool near Tiberias where the bath-keeper stated that his wife was cured of intractable rheumatism by sitting for hours in the Roman pool a treatment which, however, brought on heart trouble. The risk of "thermal debility" in baths is not to be forgotten, and should be carefully guarded against by "heart cooling."

2. *Muds.* With these, higher temperatures than in baths can be used in local applications, and the desired local and general reaction very accurately produced. Here again heart cooling is indispensable.

3. *Vapour*, with or without switching. Besides being the most soothing of all procedures for tension and pain, vapour may be made the most stimulating of all external applications. A wide range and flexibility of application give it an essential value in cold climates. The prolonged use of vapour at various and progressive grades of temperature is extraordinarily valuable.

4. *Salt.* Local and general applications of brines are entirely justified in arthritic cases, and form one of the most powerful of surface treatments.

A cure for rheumatism in the warmth of summer is traditional in most countries, and is well justified by what has been already set forth. But it is reasonable to suppose that artificial climates are likely to be most needed by frigo-sensitive persons when the external conditions are most unfavourable. It is true that certain forms of arthritis are at their worst in the hot months of the year, but rheumatic persons usually suffer most in winter and spring.

Except at Bath, the systematic treatment of rheumatism in the winter months is little practised in England. An interesting example of what can be done in a cold country with mud baths is furnished by recent reports from Russia.[15] For a number of years very good results have been obtained with hot sedimentary muds in the summer season in Southern Russia. A careful trial of the same treatment by means of exported muds has now been carried out in the winter season in several northern cities. In the winter of 1914–15 a thousand military patients were treated in this manner in Leningrad, the men being housed in warm buildings and carefully protected from intercurrent chill. Professor Alexandroff states that the results obtained from winter treatment in the towns have proved in no respect inferior to those experienced in the summer, and that there are now in Russia several properly organized clinics for this form of treatment in winter.

It would seem that the incidence of rheumatic disease in England is the most serious in the world. No one who is conversant in any degree with the complex character of these diseases will advocate one method of approach or one line of treatment to the exclusion of others. The Ministry of Health, in its pronouncement at the International Conference on Rheumatism at Amsterdam in 1927, and more than one report, has foreshadowed a threefold programme for investigation and treatment: (1) centres for physical treatment in towns; (2) development of spa hospitals; (3) an arthritis unit or units for intensive study in association with the medical schools. To this programme those who are responsible for the international league have given their unreserved support.

My present purpose is to endeavour to indicate, from rather wide experience, what appear to me to be the essential features and conditions of success of a centre for physical treatment in a northern climate. In the first place, the centre must have for its nucleus a bath clinic with its proper therapeutic elements—namely, heat, moisture, mechanical stimulation, and time. The baths and its surroundings will actually represent a climate in miniature, and it will operate by counteracting climatic influences in those who are injuriously affected by them. This means the establishment, or perhaps rather the re-establishment, in England of people's baths, where the functional disturbances associated with rheumatism can be relieved, and the development of rheumatic diseases prevented, especially in the cold months of the year.

To serve this purpose a large warmed building will be required, with a temperature approaching 70° F. in all its parts. The main feature will be the central pool or pools of moving water with its complement of gases, at the selected degree or degrees of heat. In association with

these, departments will be provided for treatment either by mud, with the proper mud kitchen, or by vapour at various temperatures, or by thermal brine. Light and artificial sunshine will certainly have a place, as well as a judicious selection of local and accessory physical treatment. There will also be ample accommodation for manipulations, movements, frictions, and switching, and couches for packs and prolonged and quiet resting. An artificial climate will pervade the place, and winter gardens with a subtropical temperature, refreshment rooms, library, games and recreations, and a gymnasium, may properly be included in the scheme. Last but not least, fountains of soft drinking water, hot and cold, will be provided in all departments for treatment, inasmuch as the free use of water internally is of great assistance to the external treatment of rheumatism.

The great majority of rheumatic persons, both in the early and later stages of the disease, and many others who suffer from chill, might well be recommended to spend from two to three hours a day in a medical establishment of this description. Men and women after the day's work would take with advantage a couple of hours for treatment, rest, and recreation at such a bath clinic. For all serious cases, especially of arthritis, warmed hostels should be available in close proximity.

Apart from the great towns, where the need for such facilities is probably the greatest, there are British marine resorts well suited for a winter cure, where rheumatic cases are already treated with benefit, and it is not inconceivable that at some future time the people's bath clinics may also be established at the spas and along the coasts.

A BLOOD SERUM TEST OF GENERAL PARALYSIS.

BY

K. O. NEWMAN, M.D.VIENNA,

PATHOLOGIST TO THE OXFORD COUNTY AND CITY MENTAL HOSPITAL, LITTLEMORE.

LANGE's gold-sol test depends on the capacity of pathological cerebro-spinal fluid to bring about a coagulation in a gold-sol whose hydrogen-ion concentration lies between *p*H 6.1 and *p*H 6.3. This coagulation is ascribed to one or several globulin fractions (Cruickshank,[1] Felton,[2] Fischer,[3] Weston,[4] Mellanby and Anwyl-Davies,[5] and others). Lange tried to extend his test to serum, but was unsuccessful; the difficulty lies in the fact that every serum, if tested like cerebro-spinal fluid, gives a strong paretic curve ascribed to globulin. I have devised a serological test of general paralysis, evolved in the course of work on the pathogenesis of the disease and of certain physiological and pathological features of the cerebro-spinal fluid. My object in this article is to describe this test and its clinical application; the work on which it is based, and my views about the cause of the reaction, will appear in another scientific journal.

THE GEL TEST.

By a process of sensitization to be described below I have been able to produce a gold-sol which, for a period long enough to enable the experimenter to examine a considerable number of serums, gives distinct and easily distinguishable colour reactions in normal and paretic serum (or, probably, in the serum of any patient whose cerebro-spinal fluid would show a paretic curve). I have also found that one drop from several cubic centimetres of glycerin which has been poured into a test tube containing a small amount of solidified serum and allowed to stand at room temperature for one minute or longer gives an instantaneous characteristic reaction with sensitized gold-sol. The serum before solidification must be shaken for a few seconds with decolorizing charcoal. The solidification is effected by heating to 80° C.; boiling is permissible, but it distinctly weakens the reaction.

Preparation of the Gold-sol.

I prepare the gold-sol according to Eicke's method, but with one or two very slight modifications. I always distil the water over potassium permanganate in a Jena glass still. Further, having added 1.5 c.cm. of a 5 per cent. solution of potassium permanganate drop by drop at intervals of about one second to the 500 c.cm. of distilled water (containing 0.5 c.cm. of 10 per cent. gold chloride and 2.5 c.cm. of a 5 per cent. solution of dextrose), beginning when its temperature has reached 90° C., I continue with a 1 per cent. solution of potassium carbonate, gradually increasing the intervals between the drops from about two to five seconds as the colour change approaches. As soon as the colour change occurs I rapidly remove the flame. The gold-sol is now ready for immediate use and can be cooled in plugged 100 c.cm. Erlenmeyer flasks under a cold-water tap.

Apparatus Required.

The requisites are as follows: (*a*) stock solutions, preferably kept in Jena glass flasks, of gold-sol prepared by the above method, and normal hydrochloric acid; (*b*) one 50 c.cm. beaker, one 100 c.cm. beaker, both preferably of hard glass; (*c*) one 50 c.cm. burette, one 25 c.cm. burette, and one 2 c.cm. burette (graduated in 0.01 c.cm.); (*d*) one dropping pipette (Dreyer's pattern), and one 10 c.cm. pipette; (*e*) a number of straight button-end dropping tubes*; and (*f*) a number of test tubes, extra strong, 4 in. by 1/2 in. A simple device (not essential, but particularly useful for dealing with large numbers of serums) can be obtained from S. W. Bush, Sir William Dunn School of Pathology, Oxford. It has been made according to my instructions, and consists of a solid duralumin pan with a stout copper inlet serving as a lid, and holding a thermometer and fifty test tubes of the size described above. I recommend that three Dreyer pipettes should be kept and calibrated as follows: one pipette marked at 0.5 c.cm. and 0.9 c.cm.; two pipettes marked at 0.1 c.cm. and 0.5 c.cm. The first pipette serves for measuring the saline, the other two for measuring the cerebro-spinal fluid. I always work with 0.5 c.cm. of cerebro-spinal fluid dilutions, adding 2.5 c.cm. of gold-sol.

"Adjustment" of the Gold-sol.

To adjust the gold-sol the procedure is as follows:

1. Four test tubes, each containing a 1 in 10 dilution of normal cerebro-spinal fluid in 0.4 per cent. saline, are set up.

2. The 50 c.cm., 25 c.cm., and 2 c.cm. burettes are filled with gold-sol, distilled water, and normal hydrochloric acid respectively.

3. 12.5 c.cm. of gold-sol are run into the 50 c.cm. beaker.

4. 19.5 c.cm. of distilled water are run into the 100 c.cm. beaker.

* Obtainable from Henry W. Bush and Co., Ltd., Rembrandt Works, Lavington Street, London, S.E.1. Price list No. 655, 1929, Catalogue No. 815.

5. 0.5 c.cm. of normal hydrochloric acid is run into the beaker containing distilled water and the contents mixed by a few rapid circular movements.

6. Five drops of the hydrochloric acid thus diluted are transferred with a drop tube, kept specially for the purpose, into *the beaker containing the* 12.5 c.cm. of gold-sol, and the contents are mixed in the manner described in 5.

7. 2.5 c.cm. of the now acidified gold-sol are run into one of the test tubes containing the 1 in 10 dilution of normal cerebro-spinal fluid. The contents of the tube are mixed by shaking.

If no change, or only a slight change, occurs in the gold-sol in the test tube the whole procedure must be repeated, with the difference that now six drops of acid are added. Adding another drop of acid to the remaining gold-sol is useless. The required degree of acidity is reached when the gold-sol, on being added to the diluted cerebro-spinal fluid, assumes a blue colour, which turns to steel-blue in approximately one minute. With such a gold-sol the ordinary events are reversed: normal cerebro-spinal fluid precipitates it; paretic cerebro-spinal fluid hardly precipitates it at all, or only to a much less degree. The beginner will therefore find it useful to set up a 1 in 10 dilution of paretic and of normal cerebro-spinal fluid, and to test both. If the difference between normal and paretic cerebro-spinal fluid is distinct, he will know that he has not added too much acid; the addition of too much acid sometimes decolorizes both fluids and makes the gold-sol unsuitable. An important point to note is that the right degree of acidity is reached when the normal cerebro-spinal fluid turns blue, and that after this a further addition of acid is not permissible. The determination of the end-point is easy on account of the sharp change.

A note is made of the number of drops of diluted hydrochloric acid that must be transferred to the beaker containing the gold-sol (see 6 above), and this number will be found to be sufficient in dealing with the rest of the stock solution of gold-sol as long as this does not undergo any spontaneous change. It generally takes ten drops of N/40 hydrochloric acid to obtain a gold-sol suitable for the reaction; consequently it is practical to begin by adding ten drops of the N/40 hydrochloric acid to the 12.5 c.cm. of gold-sol, and then only to undertake "adjusting" if it proves necessary.

Technique of the Test.

The gold-sol is now "sensitized," and the remaining procedure is as follows:

1. With a wire-loop about 0.01 gram of animal charcoal is placed at the bottom of two test tubes; the charcoal in each tube should be approximately the size of a grain of barley.

2. Into one of the two test tubes five drops of the patient's serum are dropped with a Dreyer pipette, and in the other the same amount of serum from a patient known to be paretic. The pipette must be dry and clean for each of these operations.

3. The two test tubes are gently shaken by hand for about ten seconds, care being taken not to splash the sides of the tubes more than can be helped.

4. Both test tubes are partially immersed in a beaker containing water. The water is heated to 80° C., and the serum solidified to a jelly-like mass.

5. The test tubes are removed from the beaker and 4 c.cm. of glycerin is added to each, and the tubes are allowed to stand for five minutes at room temperature.

6. From each of the test tubes one drop of glycerin is transferred by means of a straight drop tube into other test tubes; separate drop tubes must be used. The test tubes containing one drop of glycerin each are called A and B.

7. Two straight drop tubes set aside for the purpose are dipped into the beaker containing the sensitized gold-sol, and at the same time about 1 c.cm. is drawn up into each of the two tubes. It is well to make a mark at 1 c.cm., and so to adjust the rubber teats that, as nearly as possible, the same amount of gold-sol is drawn up into both tubes. After gold-sol has been withdrawn from the beaker it should not be returned.

8. The charged drop tubes are brought into position above the two tubes A and B, and discharged simultaneously with a sudden jerk. This completes the test.

Result of the Test.

The gold-sol in the tube containing one drop of "unknown" glycerin will, if the latter has stood over non-paretic serum, instantaneously turn a brilliant blue colour; the gold-sol in the tube with paretic glycerin will show a brilliant red colour. This occurs in many cases, but the result of the test is in no way invalidated if exactly the opposite occurs—namely, "paretic" glycerin turns the *gold-sol blue, and "non-paretic"* glycerin allows the gold-sol to retain its red colour; this phenomenon I describe as "reverse." It may also happen, though rarely, that the difference in colour between the two tubes is not very distinct, and in this case a repetition of the test may be necessary. The crucial point, however, is that difference in colour from that of the "paretic" glycerin indicates non-paretic serum; identity of colour indicates paretic serum. It is not essential to use fresh serum; serum several months old, and even infected, though its use is undesirable, will produce reaction.

If several serums have to be examined together it is advisable to arrange the sequence of tubes as follows, calling the tubes containing "unknown" glycerins A_1, A_2, A_3, etc., and the tubes containing "known" paretic glycerin B. Six pairs of tubes—A_1-B, A_2-B, A_3-B, etc.—should be set up at the same time, as this number just takes up the amount of "sensitized" gold-sol available.

Value of the Test.

I have applied the test in 285 cases, among which there were nine cases of general paralysis; in some of the cases I applied the test a number of times. Only one serum from a patient believed to be non-paretic gave a reaction of general paralysis, but on clinical examination of the patient concerned and examination of the cerebro-spinal fluid this case proved to be one of either general paralysis or of the rare type of encephalitis lethargica which, imitating the neurological and psychotic symptoms of tabo-paresis, may be mistaken for general paralysis. Several features in the case make me incline to adopt the latter diagnosis.

Discussion.

My views about the nature of the reaction will appear in a later paper, but I may say briefly that I ascribe the reaction to the presence of a hypothetical thermostable catalytic substance of low molecular weight adsorbed to the molecules of albumin and globulin, more loosely to the latter and travelling through the glycerin at great speed. I assume, further, that the thermostable catalyst is surrounded by a layer of protective colloid which should be capable of undergoing various chemico-physical changes in the blood serum.

In my view the order of events which characterize the onset and course of general paralysis is as follows: a primary change in the blood serum, spontaneously reversible or reversible by the chemico-physical changes in the blood serum induced by malarial treatment; and secondly, irreversible changes in the central nervous system and the meninges.

If the value of the test is substantiated I would suggest that the blood of every syphilitic patient should be subjected to it at least once a year, and if the reaction is positive malarial treatment should be applied immediately, even though the Wassermann reaction, or any other similar reaction, should prove negative in the blood and cerebro-spinal fluid. It is possible that the change occurs an appreciable time before the permanent change in the central nervous system and the meninges, and it may be that only during this interval can malarial treatment be applied with preventive effect.

I am indebted to Dr. T. S. Good, medical superintendent of the Oxford County and City Mental Hospital, Littlemore, for facilities afforded; and to my colleagues Dr. C. W. S. Davis-Jones, first assistant medical officer, and Dr. F. M. Stewart, second assistant medical officer, both of this hospital, for kindly collecting numerous samples of blood required in the course of this investigation. I gratefully acknowledge the invaluable help I have received from my laboratory assistants, W. MacDougall and J. G. Watchorne, members of the male nursing staff of the hospital.

THE ETIOLOGY OF CERTAIN LESIONS AT THE HIP-JOINT.

BY

W. R. THROWER, M.B., B.S.Lond., M.R.C.P.,

WEYMOUTH.

I PROPOSE to correlate some recent researches in the anatomy of the parts about the hip-joint, with special reference to their embryology, and to indicate the practical application of this by illustrative pathological conditions. In a paper such as this it is impossible to deal with all the various possible lesions, but I will mention a few of the more important from the standpoint of how they occur, giving an outline of the necessary treatment; this is better than taking a list of diseases and discussing them seriatim.

The first sign of the limbs in the developing foetus is seen at the third week, when the four limb buds appear; in the lower extremities the bud consists of ten lateral processes of the corresponding somites of mesoblast. As the processes grow out they as it were drag with them corresponding portions of the primitive neuroblastic neural tube, which ultimately form the spinal nerves, and in this way the twelfth dorsal to the fourth sacral nerves are formed. Recent work has shown that the lateral processes of the primitive segments consist of two separate parts—a central core of mesoblast, with a covering of mesenchyme. This mesenchyme is probably the more primitive body tissue in which stiffening takes place to form the skeleton; the original idea of mesoblastic uniformity is being gradually abandoned. As the limb buds grow out they lie at first parallel to the trunk, but by the sixth week of intrauterine life the lower limbs have assumed a position at right angles to the trunk, and some differentiation into their three mature portions has occurred. While this is taking place condensation of mesoblastic cells occurs in the centre of the bud, starting first in the proximal part of the free limb and in the tissues carrying it; these ultimately form the buried portions of the limb and also the limb girdle. At quite an early stage of condensation in the case of the lower limb the femur assumes a shape approaching in some measure its adult form. This shape is determined apparently (Hume) by the deposition on the femur of a limiting layer of cells, derived from the surrounding mesenchyme, this layer ultimately forming the periosteum of the bone. At the ends of the bars of mesoblast the covering layer is usually very thin, to allow, apparently, for the changes which occur later on in and around the epiphyseal line. When the layer is actually deficient, leakage of cells may ensue, which suggests the real origin of exostoses—comparable with the leakage of cells from beneath the periosteum of an adult bone at muscle or tendon insertions, where spurs and other outgrowths sometimes occur.

While condensation of the buried and free limb is taking place rotation has commenced in an inward and backward direction, so that the future flexor surface from being ventral becomes dorsal. When it is remembered how very fragile the foetal cells must be at this stage, in spite of the term "condensation" being applied to them, the cause of congenital malformation of the limbs or spine becomes more comprehensible. It is fairly easy to surmise the cause of congenital dislocation of the hip, the "central splint" of cells being severed where the free limb is attached to the trunk, when the limb buds rotate.

To carry explanations too far leads to difficulty, but it is interesting to remember in the case in point that an acetabulum of a kind is formed, in spite of the fact that the head of the femur has never been in its proper position. That circumstances will affect morphological change is evidenced by the more rational form the acetabulum assumes after successful treatment for congenital dislocation of the hip. All this evidence tends to support a theory of developmental anomaly as the cause of this condition, rather than of obstetrical accidents, etc.; but I suppose the explanation is of academic rather than of practical importance.

Anatomical landmarks are the most useful guides in classifying congenital dislocation of the hip, which may be of any degree, ranging from a slight subluxation of the joint to a complete derangement, with the head of the femur lying anywhere from the dorsum ilii to the obturator foramen. The most common place is situated on the dorsum ilii above the acetabulum, where it is probably driven by the weight of the body falling on an already dislocated joint; that the capsule stretches with the excursion of the bone is what would be expected from the developmental evidence already considered, the capsule being mesenchymal in origin and really part of the limb bud.

It is unnecessary to enumerate the cardinal symptoms and signs of this condition, the most satisfactory diagnostic information being that obtained by *x*-ray photographs. Before passing to the rationale of hip-joint symptomatology in general, however, a note about treatment may be permitted. The earlier the condition is diagnosed the more successful is the treatment. This is now being practically standardized as reduction of the dislocation by manipulation and fixation of the limb, fully flexed and everted in a plaster case; from this position the limb is gradually released during a period of nine months or so. The form of treatment by clamps and splints, advocated on the Continent, has been abandoned.

The hip-joint, from its very nature, is fairly stable; in its resting position it is locked by the action of the ilio-femoral ligament, or Y-shaped ligament of Bigelow, which is rendered tense by full extension and slight internal rotation of the femur, muscular strain thereby being reduced to a minimum. When the joint has to be moved again it is unlocked by slight internal rotation of the femur, and the muscles take the strain. Consequently, when any condition in the hip-joint itself, or closely adjacent to it, causes the slightest effusion, the joint capsule and the ligaments, especially the ligamentum teres, must be relaxed, and the classical flexion, abduction, and external rotation occur. External rotation beyond that which occurs with an extended locked joint is made possible by the fact that flexion has occurred first. Muscle ache on standing or walking, apart from joint pain, is thus explained, while the degree of limp is determined by the extent of the deformity and any change in the upper end of the femur which may be present. The principal nerve supply to the hip-joint is by the obturator, the motor nerve of the adductor group of muscles, and, should it be irritated for more than a short time, the adductors pass into reflex spasm, causing the secondary deformities of hip-joint disease—namely, flexion and adduction. Internal rotation follows to a greater or less degree, in spite of the normal action of the adductors, owing to the fact that the patient lies on the sound side and gravity comes into operation.

In addition to the foregoing, which may be termed the gross signs of hip-joint disease, there is another equally important group of manifestations, not so obvious, perhaps, which depend on some anatomical change in the head or neck of the femur, the consequent deformities being best elicited by means of a tape-measure and a subsequent *x*-ray examination. The normal angle of the neck of the femur is 125 degrees, and the neck has a slight forward inclination of 12 degrees; it follows, therefore, that any alteration in the angle of the neck, or any bony changes in the head or neck, will be reflected in the total length of the limb, and in the relation of the tip of the great trochanter to Nélaton's line.

The question then arises how best to distinguish between the various possible conditions which may be present when one is faced with a case suggesting trouble in the region of the hip-joint. The age of the patient is of value, especially in such conditions as congenital dislocation of the hip, which is noticed first in young children, and adolescent coxa vara in children at or just after puberty; for the rest it is not of diagnostic value, at any rate at first. Following this a history is elicited which may bring out the story of an injury, even some time previously, which broadly suggests the possibility of one of the epiphyseal group of diseases, such as pseudo-coxalgia or traumatic coxa vara. A simple epiphyseal strain, with its consequent pain and limping, usually settles down after about ten days' rest in bed, but, failing this, an *x*-ray examination will often help to exclude more serious lesions. Careful physical examination will, of course, elicit difference in the length of the

limbs, as well as bony displacements and deep-seated tenderness, the possible conditions always being borne in mind. This physical examination should always be supplemented by *x*-ray photography, which it may be necessary to repeat at intervals; it is only since the advent of radiography that any really exact knowledge of the state of affairs has been possible.

Reference to the head of the femur prompts me to say a few words about its blood supply. The head receives a variable branch of the internal circumflex artery through the ligamentum teres, while the neck is supplied by numerous tiny twigs via the retinaculae in the capsule of the hip-joint from the digital anastomosis, which also sends a branch direct to the base of the neck. Recently some German anatomists have traced out the course of these rather feeble vessels in the bone itself, demonstrating that they run remarkably straight courses to form a network at the epiphyseal line. From this fact can be explained, perhaps, the changes which occur so frequently in the young when the epiphysis is moved relatively to the shaft of the bone, as by a fall. As the result of this injury there is thrombosis of the arterial whorl at the epiphysis; this is a possible explanation of the pseudo-coxalgia which crops up from time to time in hip-joints previously the seat of congenital dislocation which have been successfully reduced but too violently.

Epiphyseal strain, when it develops in the hip-joints of children following an injury, constitutes a definite threat of future trouble if not properly treated by rest and so forth, since cases occurring presumably without infection may end in a traumatic coxa vara; should a haematogenous infection be superadded pseudo-coxalgia will most certainly occur. Fortunately or unfortunately for this infective theory of the cause of pseudo-coxalgia, most careful cultures have been made in definite cases of the condition with only negative results, but this does not prove that the condition was always such. When cultures have been successful a *Staphylococcus aureus* of low virulence has been obtained, and, supposedly, a suppurative epiphysitis would have supervened had the micro-organism been more virile. When it is considered how frequently healthy children knock themselves about with no ill result the question arises why only some should suffer, especially as the upper epiphysis of the femur is always subjected to a sheering strain. Of late the importance of calcium metabolism and its relation to infections generally has attracted much attention; this is of special importance when dealing with bony conditions. Phosphorous and calcium taken by the mouth as food can only be metabolized in the presence of accessory food substances—the vitamins A and D—balance being preserved between these two elements and the excess being excreted. This is not the whole story, in the light of Collip's researches into the functions of the parathyroid bodies, since he found that, quite apart from vitamins, the normal level of blood calcium depended on the presence of the hormone of these bodies in the circulation.

"Late rickets" is a convenient label to apply to those epiphyseal changes in patients who are too old for this disease in its generally accepted form. Is it not more desirable to recast the whole story of calcium metabolism, and to presume, at any rate for the moment, that rickets is one indication of a general metabolic dysfunction which may be manifest at any time, at any rate in the early years of life? We may go further and consider a condition such as urticaria, which is by no means infrequently present in cases of rickety and adolescent coxa vara. Does not this suggest the importance of general measures as well as local splinting, etc., in the treatment of these bone joint lesions?

In days gone by cod-liver oil was the standby in all these nutritional diseases, but of late the results have not been uniformly successful, the reason being shown to rest in its variable vitamin content. When cases of bone disease are treated by sunlight, the ultra-violet light of which synthesizes the vitamin in the skin, remarkable results have been obtained, especially in conditions such as pseudo-coxalgia, which is often most difficult to distinguish from tubercle and has been treated similarly.

Pseudo-coxalgia is essentially an epiphyseal disease, appearing first as a destructive process, quietly continuing until a natural attempt at arrest brings about hypertrophic growth of bone, frequently very soft, with the result that the top of the femur is mushroomed and coxa plana results. The Americans describe coxa plana, due to this cause, as resembling the buffer of a railroad car rather than a mushroom, the top of which is really too big in proportion to its stem to be an exact simile. Treatment in the early stages must be expectant, with rest and massage at definite times; later deformities may require adjustment.

Mention of the femoral epiphysis leads on to another condition in which it is affected—namely, certain types of coxa vara. It is impossible in a short paper to enter into a full discussion of this disease, but as a rule it is bilateral, and angulation occurs at one of three points—epiphyseal, cervical, or basal. As regards the types, these are fairly well defined, the most interesting being the infantile, or cervical, which *x*-ray evidence definitely indicates as being of developmental origin. So far as can be ascertained, it appears that a diaphyseal spur develops which has a separate centre of ossification between the epiphysis and diaphysis proper, forming a triangular wedge of bone (Elmslie). The cementing cells between the portions of bone are weakened and give way, there being two layers instead of the usual one, as a result of the strain of the body weight. In the adolescent type there is no diaphyseal spur, and the slipping of the epiphysis is due to the weakening of the cementing cells from injury to the blood supply, and presumably to faulty calcium metabolism at the place, the changes not being comparable with those of true rickets. The onset is marked by pain and limping, the limb being flexed, adducted, and everted. Treatment aims at correcting the deformity by suitable extension; it should be continued until skiagrams show that buttressing by new bone has taken place.

In a purposely short paper it is impossible to go fully into all the conditions about the hip-joint; those mentioned have been discussed very broadly to avoid dogmatism.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SCLEREMA NEONATORUM.

THE case of an infant who undoubtedly suffered from this unusual complaint, and is now alive and in good health, seems sufficiently interesting to be recorded.

The mother, aged 36, who had a history of scarlet and rheumatic fevers, indigestion apparently of hepatic origin, and several attacks of urticaria, was in poor health up to the time of her confinement on December 16th, 1929. She had been married eighteen months before she became pregnant. She does not appear to have had sufficient exercise. Her appetite was small, but she enjoyed fats in the form of butter and cream. She had mitral disease, which at first caused little inconvenience, and she complained of various "rheumatic" pains, induced by climatic changes. The father, a meagre, C 3-looking individual, has suffered for many years from chronic nasal catarrh.

The mother commenced to vomit as soon as she became pregnant, and continued, on and off, during pregnancy. She took "milk of magnesia" continuously, and had some difficulty with constipation. She lost weight, and had several attacks of bronchitis and night sweats. By the seventh month she complained of palpitation, swelling of the ankles, morning and evening, and of attacks of fainting. Her urine, which was tested frequently, never contained any albumin, but phosphates and urates were present in excess of normal. For the last two weeks prior to her confinement her abdomen felt "senseless." After being nine hours in labour she was given chloroform and delivered with forceps of a female child, which weighed 5¼ lb. She recovered from the confinement fairly well, but had several attacks of vomiting, and the involution of the uterus was delayed. She had no milk till the ninth day.

Delivery was hastened in view of the mother's cardiac condition. On the cord, which was unusually thick, there was, about one and a quarter inches from the umbilicus, what proved to be a haematoma, two and a quarter inches long, dipping into Wharton's jelly. The placenta appeared to be normal. The child seemed to be heavier than it actually was, and its skin was hard and stiff, preventing it from moving its limbs, but not interfering with sucking. The hardness, which apparently involved the whole skin, seemed most pronounced and remained longest over the buttocks, which were dark blue in colour. At no time did the skin pit on

pressure, and there were no haemorrhages. The hardness disappeared gradually about three weeks after birth, and was followed by a general desquamation.

Four days after birth the child developed a paronychia of its right index finger, and a few days later a swelling was observed on the inner side at the middle of the right upper arm, over the brachial artery. This gradually increased in size, and was diagnosed as an enlarged gland, an angioma, or an abscess. It never gave any fluctuation, but felt like rubber, and moved freely under the skin. In view of the paronychia, it was incised on the twenty-fourth day, and about 1½ drachms of pus were evacuated. The wound healed without delay, and at the present time, three months after birth, the child weighs 10¼ lb., and is happy and apparently in good health.

In view of the unknown pathogenesis of this obscure condition it is interesting to note: (1) the unsatisfactory condition of the mother's health, with symptoms pointing to allergy or hepatic insufficiency; (2) the delay in lactation; (3) the localized septic focus in the infant, which may have had something to do with its survival and recovery.

Wolverhampton. W. GOLDIE, *M.C.*, M.B., Ch.B.

ANTERIOR POLIOMYELITIS SIMULATING LANDRY'S PARALYSIS.

THE following case seems to be of sufficient interest and rarity to warrant publication.

On October 23rd, 1929, at 10 a.m., I saw Miss F., aged 35, a nullipara. She complained of vague pains in the back and lower limbs, but was afebrile. She did not look ill. The pulse and temperature were normal. The next day the condition was unchanged, but the temperature was 100.5° F.

On the morning of October 25th the patient was found to have flaccid paralysis of the lower limbs; the knee-jerks were absent; the plantar reflex was flexor on both sides. The abdominal cutaneous reflexes were indefinite; cutaneous and deep sensation apparently normal.

On October 26th no abdominal reflex was present and the plantar reflex was abolished. The abdomen was definitely distended. The patient urinated with difficulty, but apparent intestinal paresis was present. Temperature 101°, respirations 17, pulse 99. Towards night olive oil and soap-and-water enema, *plus* 1 c.cm. of pituitrin, gave a scanty result, but relieved the abdominal distension temporarily.

On October 27th the abdomen was again distended. The patient looked ill and distressed. Respirations had quickened and were *entirely thoracic*. There were tremors of the tongue, face, and arms; the pulse was very fast and irregular. Speech later on in the day became incoherent, articulation thick; movements of arms erratic. The patient died towards midnight of bulbar paralysis. The ultimate picture was certainly like asphyxia.

The case was obviously poliomyelitis, but of a rapidly ascending nature, with main incidence on the anterior cornua of grey matter. Its chief features were very similar to those of Landry's paralysis, except for the fact that there was obvious acute infection (fever) present. Unfortunately there were no facilities to take the electrical reactions of the paralysed muscles, which in Landry's paralysis are supposed to show no reaction of degeneration. Such a test would doubtless prove valuable in the differential diagnosis.

Ingleton, West Yorks. J. MACLEOD, M.B., Ch.B.Aberd.

PROPHYLAXIS AGAINST DYSENTERY BY ORAL VACCINES.

CASES of diarrhoea and dysentery have been occurring at Hillsleigh School (a branch of the Royal Eastern Counties Institution, Colchester) during the last few years. The children are of low grade, and it was deemed necessary to prevent further outbreaks. All the stools examined bacteriologically proved negative, and it was therefore decided to test the blood of all the patients.

Samples were taken from 48 children; in 26 cases the serum did not agglutinate Flexner's bacillus, *B. dysenteriae* Y, or Shiga's bacillus in any of the dilutions employed—namely, 1 in 10, 1 in 25, 1 in 50, and 1 in 100. In 14 cases the serum agglutinated a strain of Flexner's bacillus in dilutions of 1 in 10. In 4 cases it agglutinated Flexner's bacillus in dilutions of 1 in 25 as well as 1 in 10, but weaker dilutions were negative. Five of the 18 serums which agglutinated Flexner's bacillus also agglutinated Shiga's bacillus in a 1 in 10 dilution, but weaker dilutions were negative. Seven cases which agglutinated Flexner's bacillus also partially agglutinated a *B. dysenteriae* Y suspension in a 1 in 10 dilution, but weaker dilutions were negative. Four cases agglutinated *B. dysenteriae* Y in 1 in 25 dilution, but no other type.

All the cases at this branch home, whether positive or negative, received a course of oral antidysentery vaccine six months ago, each patient having three doses of 5 c.cm. each. This vaccine contains equal parts of Shiga's and Flexner's bacilli, and is given on three consecutive days. There was no reaction of any kind, and up to the present no case of dysentery has occurred since the patients received the vaccine.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

LANCASHIRE AND CHESHIRE BRANCH: SOUTHPORT DIVISION.

Surgery in Relation to Diseases of the Colon.

ON March 27th Professor D. P. D. WILKIE gave a British Medical Association Lecture to the Southport Division, entitled "Surgery in relation to diseases of the colon." The meeting was held in the Assembly Room of the Prince of Wales Hotel, Southport, and was well attended, there being about forty members present, including visitors. The lecture was made particularly interesting by the demonstration of lantern slides.

Professor Wilkie said that more disabilities arose from disorders of the large bowel than from anywhere else in the body; apart from acquired disorders there were many congenital causes which might render the normal function of the colon impossible. The small bowel was the active segment of the digestive canal, and therefore the colon and the stomach, with less digestive activity, were much more liable to be the seat of pathological changes. The proximal colon was the part from which toxic absorption might be expected. The lecturer, who dealt mainly with non-malignant diseases of the colon, compared the caecum and caeco-colic tract to the stomach, showing how it suffered from the same type of disease—namely, ulcers, the constricting as well as the fungating types of carcinoma, and occasionally from a large single diverticulum. He also commented on dilatation, diverticulum, and tuberculous stricture of the caecum, and described the disorders of the nerve supply of the colon. *Referring* to the spastic types of constipation, he said that it was beyond dispute that many individuals who enjoyed good health had a mobile proximal colon. In certain cases where there had been long complaint of dragging on the right side fixation of the colon had given immediate and lasting relief. The operation of colopexy was of undoubted value in some cases. In atonic dilated caecum the patient usually complained of right-sided abdominal discomfort, and showed evidence of intestinal toxaemia. There was constipation, lassitude, and acute pain in the right iliac region suggestive of a lesion of the appendix. X-ray examination revealed a low dilated caecum, with marked delay in emptying. Treatment by liquid paraffin and senna often greatly benefited these cases, but operation would, of course, give the surest relief: removal of the appendix and plication of the caecum abolished pain and facilitated the emptying of the caecum.

Professor Wilkie then referred to the redundant colon, and remarked that cases of colon stasis had been associated with this condition. Some individuals have a colon one and a half times as long as the average. It might be that the pelvic colon alone was redundant, necessitating resection

of a loop: in other cases the whole colon was long, causing chronic disability, and, indeed, complete invalidism. It was in this latter type of case that such marked success had been achieved by colectomy; this operation might be performed in stages, either by preliminary colostomy or by a preliminary anastomosis between the caecum and colon, followed by a second operation of resection of the colon. The results of this operation were striking, and proved the toxic character of colon stasis. In colitis only very severe cases needed surgical treatment; ileostomy was the operation of choice. The ordinary case of colitis did well with lavage, and vaccine or sero-therapy. The lecturer discussed the indications for surgery in diverticulitis of the colon—namely, perforation, pericolic abscess, subacute obstruction, and recurring attacks with disability. At one time he had been greatly attracted by Arbuthnot Lane's work, but gradually he became prejudiced. In the last few years the few cases of colectomy he had performed had proved to be the most successful operations he had ever undertaken; they were not free from danger, because, if the operation proved easy, it was probably not required. In cases of real necessity it was extremely difficult, owing to the number of adhesions and to the patient being very much below par.

The lecture was warmly received by a most interested audience. Questions were asked by Dr. E. W. LEWIS (chairman of the Southport Division), Mr. HUGH REID of Liverpool, Mr. GRAHAM BRYCE of Manchester, Dr. CALLAM of Burnley, and Drs. ANDERSON and CRONIN LOWE of Southport, and Professor WILKIE briefly replied. Dr. BENTALL proposed, and Dr. ANDERSON seconded, a vote of thanks to Professor Wilkie for his most lucid and instructive lecture.

Reports of Societies.

TECHNIQUE AND RESULTS OF PROSTATECTOMY.

IN the Section of Urology of the Royal Society of Medicine on May 22nd, with Mr. FRANK JEANS presiding, a discussion took place on the technique and results of prostatectomy.

Mr. KENNETH WALKER, in opening, said that he had been struck with the discrepancies between the methods employed by members of the British school of prostatectomists. The nearer a technique reached perfection, the fewer were the variations, and the fact that surgeons differed so widely in their methods showed that perfection was far from being attained. The methods of dealing with haemorrhage—one of the three difficulties most likely to be met with during convalescence, the others being sepsis and obstruction—were very varied. He himself had encountered some failures in every method. Packing had certain disadvantages, the chief being the increased sepsis, and the unpleasant state of the bladder and urine when the packing was removed. Therefore when bags came into use he eagerly adopted them, and applied them for two years in various forms, but in several cases the bag did not satisfactorily control the haemorrhage. Sir John Thomson-Walker's open method of prostatectomy was distinctly a move in the right direction; it was an attempt to substitute for a blind operation one which was precise and gave control under the eye. The speaker had made use of the open operation, but he found that although in itself it was excellent, there were many cases for which it was manifestly unsuited, cases in which the extra time necessary was, if not fatal, at least dangerous. Still later a method had been suggested by Harris in Australia, which aimed at making the operation still more exact by obliterating the prostatic cavity. He had not had sufficient experience of that to pass final judgement, but he knew that with a sharp boomerang needle a fair amount of haemorrhage could be produced during the process of inserting the lateral sutures. The technique must vary, therefore, with the patient. Lately in those cases not suited for the open operation, he had gone back to packing, but the question was how long to leave it in. Haemorrhage might occur from two to five days after the removal of the packing, apart from any question of secondary haemorrhage later on; he had therefore extended the time for which the packing remained in position. The chief difficulty was that it increased the amount of painful spasm. With regard to sepsis and the part played by a urethral catheter in combating it, he added that he did not tie the catheter and leave it in at the time of operation, but it was useful subsequently for drainage, and later still during the final stages of convalescence.

Mr. SWIFT JOLY said that he had looked up the figures of the cases treated at the hospital by Freyer's technique; they numbered 198, and there had been nineteen deaths. Four of these deaths occurred on the first day after operation, and were undoubtedly due to a mixture of shock and haemorrhage. After that he started packing, and had 159 cases, with fourteen deaths, no death occurring immediately after the operation; one patient had died on the day after the removal of the packing, and all the others about the second or third week. Since starting with the Thomson-Walker open operation, which had given the best results, he had operated on 207 cases, and had had seventeen deaths (8.8 per cent.), but no death in the first week. The causes of those seventeen deaths were: pulmonary embolism (one), myocarditis (one), influenza (one), pneumonia or broncho-pneumonia (four), and pyelonephritis (ten). With the Thomson-Walker method the immediate deaths had been wiped out. The disadvantages of the Freyer method were inadequate haemostasis, sepsis, risk of contraction of the prostatic cavity, and shock. The method of packing the cavity had the disadvantages of pain, haemorrhage after removal of the packing, and possible sepsis. With regard to the Thomson-Walker operation, he had not at first liked the lengthening of the time the patient was on the table; he had tried the method tentatively at first, but he was now pleased with it, and would be very sorry to go back to any other operation. Shock was practically negligible, and sepsis was undoubtedly diminished.

Mr. JOHN EVERIDGE said that the preliminary treatment was of importance, a few days in a hospital or nursing home being a great advantage. He regarded the Thomson-Walker operation as ideal; if the technique was faithfully followed post-operative obstruction was almost impossible. When the Thomson-Walker operation was not possible Mr. Everidge performed a two-stage operation. In cases where the second stage followed at a short interval it was important to fix the tube at the upper end of the wound. He nearly always gave a general anaesthetic for the first stage, for, although this was not absolutely necessary, it furnished the means for having a kind of "dress rehearsal" for the big operation which followed. He favoured the use of the Pilcher bag. Looking over the records of his cases, he found that the vast majority of deaths had been directly or indirectly associated with haemorrhage. One post-operative complication which had to be borne in mind was ileus, and to prevent this he made a routine practice of putting a small tube in the rectum. With regard to results, he had studied his last 150 cases, and had found eight deaths directly or indirectly due to haemorrhage; there were four deaths from primary shock, three of these after stovaine anaesthesia, and the total mortality was 10.66 per cent. A one-stage operation was performed in 93 of the cases, and a two-stage method in 57.

Mr. CLIFFORD MORSON supported the open method of suprapubic prostatectomy. He had heard a distinguished foreigner describe the advantages of the perineal route, but, so long as permanent incontinence was a complication, he thought that few surgeons would endanger their reputation by performing an operation by that method. His own technique was similar to that of Thomson-Walker, except that he did not tie in the catheter at the operation. As a pupil of Freyer, he knew from personal experience that though the immediate results of his procedure had given a low mortality, post-operative obstruction had occurred much too frequently. This disastrous complication had been eliminated by the Thomson-Walker technique. A criticism had been raised that there was more shock with the open method, and he agreed that this might be the

case in the hands of a slow and clumsy operator. Rapidity of operation, consistent with thoroughness, was all-important, but it was a fallacy to suppose that haemorrhage caused shock. At the Annual Meeting of the British Medical Association at Portsmouth he had read a short paper on the division of the vas deferens after prostatectomy, which was published in the *Journal* (1923, vol. ii, p. 1032), but few surgeons in Great Britain had felt disposed to adopt the technique, though it was followed by urologists of repute on the Continent, and by a great many in America. After describing the operation, Mr. Morson said that it made it possible to guarantee to the patients that whatever complications might follow they would never suffer from orchitis. He gave the figures for his last 128 prostatectomies, conducted according to the Thomson-Walker technique at St. Peter's Hospital. Cases in private practice were excluded, so as to avoid any suggestion of an attempt to improve on purely hospital statistics. Of the 128 cases, 26 were complicated by such conditions as stone, stricture, and diverticulum; the remaining 102 included cases of pre-operative retention and uraemia. Of the 26 patients with complications such as stone, etc., two died, and of the 102 patients seven died, so that the total mortality for the 128 was just over 7 per cent. The patients remained in hospital after prostatectomy for an average of 28.5 days.

Sir JOHN THOMSON-WALKER said he always used the retained catheter; it was employed in order to help the washing, not for drainage at all in the first instance, and was taken out on the seventh day. He was increasingly inclined to give continuous irrigation; this was extremely easy with a retained catheter. If the patient had not passed urine by the twelfth day the catheter was replaced, this time for the purpose of drainage. On the average, taking his private cases, the urine was passed after 11.6 days, and the wound was dry after 16.2 days, a result as good as, if not better than, that obtained with the perineal operation. All cases could not be treated by the routine operation, but the number of cases in which he did not perform the routine variety was not large. In some the operation was impossible because of severe sepsis, with infection of the kidneys, and it was necessary to drain the bladder by suprapubic cystotomy. He believed the open operation was too severe for many of the cases in which prostatectomy was required as a secondary operation. It was also wise not to spend too much time when operating on the very old or feeble patient, or in the presence of serious complications, such as bronchitis; in such cases he performed prostatectomy, if it was necessary, by the closed method. The time taken by him was 17½ or 18 minutes; if the suture at the base of the bladder was not inserted he could do it well in 13 minutes. Shock was not a necessary factor with the open operation. Sir John Thomson-Walker then repeated a number of the comparative figures with regard to mortality and duration in private and in hospital practice which he gave in his recent third Lettsomian Lecture (*British Medical Journal*, March 15th, p. 512). He thought the reason why better results were obtained in private practice was that the patients were attended after operation by specially trained nurses and by the surgeon who had performed the operation, and who had had a long training in the complications and their rapid treatment. He did not think it necessary to keep the packing in for more than forty-eight hours; if afterwards there was bleeding the packing could be replaced.

Mr. G. E. NELIGAN said that, after enucleation of the prostate, he used the Pilcher bag, which he filled with air and tethered to the right thigh. One important point was not to let the patients heal too soon; the majority of complications occurred because of a too early passing of urine. He never encouraged any patient to pass urine before the end of three weeks. If urine was not passed by then he put in a bougie and tied a catheter. In his last 100 cases there were five deaths; the average healing time was 25½ days, five cases required 40 to 44 days to heal, and two which developed strictures, and had to be reopened took sixty days. In the previous 100, using different techniques, there were eight deaths, and there were complications which, he was sure, were due to allowing the patients to pass urine too soon.

Mr. WINSBURY WHITE considered that the more experience that was gained by young surgeons the more would they tend to do one-stage rather than two-stage operations; in other words, so long as they were in the dark, they would be wise to think rather of the two-stage than of the single-stage operation. He had had the temerity to venture into the perineal region a few times, and if the technique was followed carefully that method gave as perfect a result as one could wish. He had also followed Mr. Morson's plan of dividing the vas deferens, and had never had a case of epididymitis; it seemed to him a very sound preventive measure.

Mr. JOCELYN SWAN referred to the value of the long incision which Sir John Thomson-Walker had advocated; this enabled the surgeon to see what he was doing. He wanted not only to see but to anchor the prostate, which he did by means of forceps, and made a semicircular incision around the posterior part with a pair of scissors. The two things against which it was necessary to fight were haemorrhage and sepsis; the first was undoubtedly controlled by the open operation. He did not make a practice of putting a suture in a continuous line around the posterior two-thirds of his cavity, but he inserted two lateral sutures, especially if he saw bleeding points, which were apt to occur on the margins. He used these sutures also as tractors, because a little drag on them would open up the cavity, and it could be seen whether there were any tags or pieces left which required removal. He thought it was time the use of the term "two-stage prostatectomy" was given up. The first operation had nothing to do with the prostate: it was a preliminary operation to free the patient from his renal troubles.

Mr. CYRIL NITCH agreed that open prostatectomy was the ideal form. In his last 100 cases, 41 were one-stage and 59 were two-stage operations. The mortality in the first category was 3.7 per cent., and in the second 10 per cent. The two-stage operation was performed on patients who were too ill to withstand the shock of the one-stage operation. The interval between the two stages varied enormously; it depended solely on the recovery of the patient either from his sepsis or from his renal deficiency. He found in fifteen of his cases that the bladder required drainage for periods of over a month, and in three of them for six, seven, and fifteen months respectively. With regard to the control of primary haemorrhage, he had practically given up all bags, packs, and plugs. If the haemorrhage was profuse at the time of operation, he inserted a bag, but this happened very rarely. Eight of his patients had epididymitis afterwards; two of them had had a catheter tied in after the one-stage operation. In two of the 100 cases there was post-operative obstruction; in both of these the Freyer operation had been followed. Among the two-stage cases, nineteen had chronic retention, thirteen had retention and cystitis, and there were seventeen with over ten ounces of residual urine, with or without cystitis.

Mr. SYDNEY MACDONALD remarked that serious haemorrhage did not often occur on the table; when it did the only thing was to ram in a plug quickly, and leave it in, as a rule, for forty-eight hours. With regard to reactionary or secondary haemorrhage, which occurred later on, he had not plugged a case for some years past. The chemical pathologist grouped his cases for him, and if he was at all worried about the haemorrhage he transfused at once. Transfusion had never failed him; even in serious haemorrhages it acted like a charm. When ileus occurred it was very often a uraemic rather than a septic manifestation. The difficult patients were those who developed uraemia without any preliminary danger signals. Mr. J. B. MACALPINE had had within the last twelve or eighteen months two cases with severe trouble from ileus; in each of them he was convinced that the trouble was due to uraemia. He adopted the Thomson-Walker technique for prostatectomy, with the variation that on opening the bladder he did not allow the urine contained therein to flow out into the suprapubic space; it was sucked away so that there was no contamination. With regard to means of stopping the haemorrhage, he looked upon the bag as a non-surgical instrument. The greater number of

haemorrhage cases might be left to take care of themselves. More rapid healing and diminution of sepsis would be obtained if the wound were kept completely dry by suction. Mr. E. T. C. MILLIGAN referred to the value of diathermy in controlling primary haemorrhage after enucleation of the prostate. It was useless to push the electrode into the prostatic bed, but if the bleeding points were first picked up, the prostatic bed being dried, those points could be sealed off quite easily.

Mr. E. W. RICHES, taking up the remark of one speaker about contamination of the wound by reason of a full bladder, said that it had always surprised him that urologists should fill the bladder; it was quite easy to open it without the necessity of distending it with fluid. He now arrested haemorrhage by the routine use of the Pilcher bag. He had done away with all traction methods, splints, weights, and apparatus; these were uncomfortable and occasionally harmful. The bag fitted snugly in the prostatic cavity, and it arrested haemorrhage before the patient left the operating table. The bag also had a value in that it prevented the cavity from collapsing, and it contributed to the prevention of post-prostatectomy obstruction. Mr. GALE had had the opportunity of observing many methods employed by urologists. He thought that bags and packing should be avoided where possible. Open operation was certainly the best, but he had seen a patient leave the hospital at nineteen days and return in a few weeks with obstruction. Incontinence more frequently followed the fibrous type of prostate than the ordinary type. Mr. HOPE CARLTON uttered a warning against the suction method, which in his experience had given rise to accidents. Dr. HAROLD DODD mentioned preoperative treatment in prostatectomy cases; it should extend over at least a week, sedatives being given every night and salines three times a day. To push salines before operation was of great benefit, and the same measure was valuable in the treatment of post-operative ileus. After the operation the temperature sometimes went up markedly, whereupon the hourly administration of potassium citrate during the day had remarkably beneficial results.

Mr. JEANS, from the chair, said that his impression was that the adoption of the open operation represented a falling into line with the general progress of surgery. It prevented immediate haemorrhage, and therefore did away with packing or bags as routine procedures. With regard to Harris's method, reported from Australia, he was of opinion that the prostatic bed was not the place for plastic surgery. If an ordinary operation was performed where haemorrhage was not expected, and it was found to be going on, it was a good measure to take out the tube, whereupon the musculature contracted, as did the uterus when a retained placenta was removed, and the haemorrhage ceased.

INFECTIOUSNESS AND IMMUNITY.

AT a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on May 23rd, with Dr. F. E. FREMANTLE, M.P., in the chair, a paper was read by Dr. PERCY STOCKS, reader in medical statistics in the University of London, on infectiousness and immunity in regard to chicken-pox, whooping-cough, diphtheria, scarlet fever, and measles.

Dr. Stocks said that a survey of the pronouncements of epidemiologists as to the most important factors in the control of epidemics left one with the impression that these exhibited to a remarkable degree at least two of the characteristics of the phenomena of which they treated—namely, variability and periodicity. The last swing of the pendulum seemed to have brought about, rapidly and unmistakably, the viewpoint that immunity was the most interesting and perhaps the most important of the factors concerned in the mechanism of epidemics. There were two methods by which immunity changes in a population might be studied by means of notification records: first, by measuring the apparent infectiousness of cases of the disease at different periods of time; and secondly, by actually following up contacts intimately exposed to infection and comparing their subsequent behaviour with control groups not so intimately exposed. An index of infectiousness was wanted which, whilst avoiding the assumption that there was no reservoir of infection other than clinical cases, and allowing for changes both in the facility of transmission from case to case and in the proportion of non-immune persons in the population, would yet be sufficiently simple to calculate to make it of practical use to public health workers not trained in mathematics. In a previous paper he had defined such an index, and termed it "the index of apparent infectiousness." It involved the definition of a secondary case, for the purpose of the index, as a child of defined age who developed the disease at a defined interval of time after a person residing in the same house, the interval being chosen to embrace most of the possible range in the incubation period. After giving a description of his methods of computation, Dr. Stocks said that the resulting index of apparent infectiousness was the product of two other indices not so readily measured—namely, the index of true infectiousness or relative facility of transmission from person to person, which was subject to sudden fluctuations, and the index of communal susceptibility. The index of apparent infectiousness was very easily measured by merely sorting the notification forms into alphabetical order of streets, bringing together all pairs of cases occurring in the same house, with the specified interval between the onsets and with the specified age of the second case. The behaviour of this index, considered in relation to the epidemic curve, could indicate something about what was happening to the factors of which it was a product, for it could be safely said that the immunity of a population did not change in a sudden or explosive manner, and hence such sudden fluctuations in the index as were statistically significant must be attributed to changes in facility of transmission, and that a gradual rise in the index continuing over years without reference to seasonal influences was almost certainly due to changes in the immunity index.

After a further close description of his methods, Dr. Stocks, with the aid of charts, described the application of them to the particular diseases covered by his paper. In the case of diphtheria and scarlet fever the changes in apparent infectiousness during the five years 1925–29 occurring in St. Pancras had been worked out for comparison with the other diseases. In diphtheria no sudden fluctuations were evident in the index of apparent infectiousness, but only gradual changes. His data were not extensive enough to prove that sudden fluctuations, occasioned, as they must be, by changes in true infectiousness rather than communal immunity, did not occur in diphtheria, but the contrast with the other diagrams suggested that they were not characteristic, and that this might be the reason why epidemics of an explosive character were also not characteristic of diphtheria. The calculations made on the basis of these St. Pancras figures suggested that there were seven or eight immunizations to every clinical case notified, and this certainly agreed with the estimate made in Baltimore from Schick tests, in which there were seven latent cases to each clinical case. He thought, however, that this was an over-estimate, for the assumption that all the children born into the population were going to be exposed to diphtheria infection, even in London, was not, in his opinion, justified. It had been proved conclusively that many children brought up in middle-class homes remained Schick-positive, and most of these had presumably escaped exposure to the bacillus in any considerable doses. If it were supposed that in St. Pancras one-third of the families were sheltered from exposure to diphtheria, and that one-third of the births were into such families, certain consequential computations would lead one to suppose that about 35 per cent. of the whole child population under 10 were susceptible, which was not unreasonable. He also discussed the epidemic and the immunity curves in scarlet fever, and suggested that the progressive decline in scarlet fever incidence over the last century had been accompanied by, or caused by, a progressive increase in the communal inherent immunity, and in the capacity of the population rapidly to acquire such immunity without severe reaction when exposed to infection, a capacity which might also be inherited. With regard to whooping-cough, he produced some figures on the basis of the notifications in

Holborn and in Wandsworth, and his conclusion was that there was strong evidence against the existence of latent immunization to whooping-cough being acquired by close contact; but nevertheless, in spite of little isolation of cases being practised at home, and the length of the infectious period, it appeared that out of 721 contacts under 10 who had never had whooping-cough only 187 contracted the disease within two months, and 221 within four years, of exposure. This suggested that about 70 per cent. of contacts under 10 years of age who had not had whooping-cough would escape it altogether. It must be concluded that the bulk of children escaped whooping-cough by virtue of an inherent immunity rather than by avoiding contact with infection. Chicken-pox offered in this country an almost virgin soil to the statistician, apart from some hospital statistics. Here, again, he produced figures from Paddington, where the disease had been notifiable for some years, and said that the facts might be explained if it were supposed that about one-half the children born had an inherent immunity to chicken-pox and escaped the disease for that reason. Another quarter would have chicken-pox by 6 years of age, leaving about a quarter of any random sample about that age susceptible. On the other hand, the facts could be equally well explained by latent immunization with about one latent case to each clinical case, and to settle which was the correct explanation, or whether both played a part, further data were necessary. The combined evidence suggested that a certain proportion, possibly about a quarter to a third, of children born retained an inherent immunity, and that latent immunization protected others, possibly another quarter. In the course of some brief remarks on measles, Dr. Stocks showed by figures what must happen to the child population in an urban area when subjected to a measles epidemic, assuming the occurrence of an epidemic every two years, the production of latent immunes at the rate of three to each case, and the loss of latent immunity at the rate of 50 per cent. in one year and 100 per cent. in two years. It appeared that on this basis almost complete immunization of the mobile portion of the child population (aged 3 and upwards) would be brought about before the epidemic ended, leaving only very young children unprotected. Finally, with regard to German measles, or rubella, he thought it must be assumed, on some figures from St. Pancras, that there was widespread inherent immunity to German measles, or else that latent immunization was an important factor as in measles; and which of these was the correct explanation could only be settled by further research. He urged that everything possible should be done to make notification records of all these diseases as accurate as possible, for important advances in the knowledge of the mechanism of epidemics could undoubtedly be made from a study of them.

Sir WILLIAM HAMER said that he could not understand how it was possible to believe that there were three latent cases for each recognized case of measles. If measles in the London elementary schools were taken, investigations had shown that a second crop of measles in a school outbreak exhausted practically all the susceptible cases. If there were three latent cases for every recognized case, why was it that in the infants' departments of the London schools, when the disease "got going," all the cases were recognizable cases? He submitted that what had been called the "firing off of the gunpowder heaps of susceptible children" was really the factor which governed the whole situation. It would account for the sudden fluctuations which Dr. Stocks had described. The moral of it all was that the recommendation made by Dr. Stocks as to the desirability of improving notification records should be supported by all epidemiologists.

Professor Major GREENWOOD made one or two minor criticisms of the paper before affirming his complete agreement with the general argument of Dr. Stocks. He had never been able to believe that the mysterious change of virulence in an organism could be demarcated by some artificial boundary like Westminster Bridge. He had also an objection to the view, suggested in the paper, that the word "case" and the word "patient" were synonymous. In his own limited academic view, a case could have no age at all. The difficulty which all workers experienced in this subject was the liability to argue unconsciously in a circle. Dr. Stocks made some calculations on the assumption that all families were at risk of infection by scarlet fever—at first sight rather a startling proposition. But he thought it was a case of arguing in a circle. One made certain assumptions as to what proportion was naturally immune, and then one was rather in danger of turning round and concluding that the results agreed with those assumptions, tending to forget that they were part of the original hypothesis. Professor Greenwood went on to give certain illustrations to show that in these questions of the distribution of cases in families the state of affairs was much more complicated than might be at first suppo-ed. Dr. Stocks was certainly right that one had to separate out this question of acquired immunity and to consider the mechanism of it, and when an acceptable mechanism from the laboratory point of view was arrived at, an hypothesis would have finally to be chosen which best fitted the actual observational data. What the statistician wanted was not absolute truth, which was unobtainable, but an accurate standard of what people meant when they made these returns.

Dr. E. W. GOODALL remarked that in measles, chicken-pox, rubella (a name he preferred to German measles), and whooping-cough there was no clinical evidence of carriers, or at any rate of carriers for any length of time. It was almost unheard of for a person who had had these diseases to go out of hospital and give rise to cases outside. Therefore he was not disposed to agree that immunization was produced in these diseases by carrier cases. He doubted very much whether there were many missed cases of measles or rubella; there were many unnotified cases, but that was another matter. Of four common diseases, measles came first in point of infectiousness, chicken-pox came next, mumps third, and whooping-cough last of all.

Dr. W. BUTLER said that it was very interesting that the Section should have a paper attempting to measure particular kinds of immunity. During what might be called the bacteriological period attention was devoted to the infecting agent, and for a long time the part played by immunization was ignored. It was obvious from the first that to be infectious there must be susceptibility, but Dr. Stocks had carried the matter to a degree of unusual definiteness and precision. The speaker would have thought that measles presented to a less degree than most infections immunity acquired in this manner. At the age of 4 or 5 not more than 10 per cent. of children could possibly become immunized in this form. At birth there was congenital immunity, almost absolute for the first six months, and this gradually declined until 4 or 5 years of age, when the highest degree of susceptibility was attained, and from then onwards permanent immunity appeared to be increasingly conferred.

Surgeon Captain DUDLEY said that lately he swabbed 200 boys eight times in the course of the year, and 45 per cent. of those boys were found to be carriers of diphtheria bacilli. As regards diphtheria bacilli, everybody in London was infected over and over again, and why they did not get diphtheria he did not know. A large number of Schick-positive people could, unless conditions were suitable, come in contact with diphtheria, and yet not get clinical diphtheria. He added that he was a strong believer in variations of the qualities of the infecting agent.

Dr. J. D. ROLLESTON said that the medical officers of fever hospitals presented a very interesting field of study. It was a remarkable fact known to everyone that the staff of fever hospitals were comparatively immune to the infectious diseases which they had to look after, and that it was chiefly those who had just joined the staff who were most likely to go down. Medical officers remained immune to the diseases during the two or three years they were on the staff of the hospital, but afterwards they might return to the hospital to see their friends, who might show them some interesting cases, and then they contracted the disease. A distinguished French epidemiologist had worked out that no less than 35 per cent. of doctors in the infectious diseases departments of the Paris hospitals were Schick-positive.

ENDOMETRIOMA.

AT a meeting of the North of England Obstetrical and Gynaecological Society at Liverpool on March 21st, with the president, Dr. J. W. BURNS, in the chair, Professor D. DOUGAL (Manchester) described a case of endometrioma of the abdominal wall occurring in a married nullipara aged 44.

Professor Dougal said that the patient had had an operation fifteen years previously for a gangrenous appendix, and for seven years had complained of pain at the lower end of the scar before menstruation. She had in addition a uterine fibroid reaching to the umbilicus, which when she was operated on was free from the abdominal scar. A tarry cyst was discovered at the operation. It arose from the left ovary, which, however, did not show characteristic glands or stroma of an endometrioma, but the excised tender portion of the abdominal scar was typical.

Dr. H. H. GLEAVE (Liverpool) contributed a note on endometrial autotransplants in the rabbit, quoting the results of observations on forty-five rabbits in which shavings of endometrium were tied into an incision in the liver. These developed into enormous cysts, which, however, reached a maximum of growth in two months, and were no bigger a year later. Dr. Gleave said that the papilliferous condition of the uterus seen in rabbits in a condition of pregnancy, or pseudo-pregnancy, was exactly reduplicated in the endometrium of the cyst from the influence of the corpus luteum hormone. Similarly, the oestrous rabbit showed cysts with thickened endometrium like the blunt folds of the uterus. After oöphorectomy both the uterus and cyst atrophied, but the injection of twenty-five rat units of oestrin daily for a week restored the endometrium to the oestrous type. Injections of pulped endometrium into the ear vein gave negative results. Vascularity of the site of implantation favoured the taking root of the implant, and Dr. Gleave concluded that the muscle of the implantation cyst arose from the graft itself, and not by metaplasia of the local tissue. These experiments, he considered, offered support for Sampson's theory of the origin of endometriomata.

Dr. J. W. A. HUNTER (Manchester) said there were two factors in the growth of human endometrioma implantation and devitalization at the area of implant. Professor BLAIR BELL (Liverpool) did not agree that the papilliferous condition of the rabbit endometrium was always due to pseudo-pregnancy; it could occur as a result of long-continued oestrus. Professor DIBLE (Liverpool) thought the experiments mainly demonstrated that the endometrium of the cysts and uterus was in the same condition at any one time.

Inversion of the Uterus.

Professor BLAIR BELL described a case of acute puerperal inversion of the uterus which had occurred in a three-para who had had a spontaneous termination to a full-term pregnancy. When examining the woman half an hour after the accident he found that the uterus and cervix were completely inverted, the placenta being centrally attached to the fundus. Shock was not marked, so under an anaesthetic the placenta was detached and the inverted uterus manually replaced. After a slightly febrile convalescence the recovery was uninterrupted, and two years later the patient had an uneventful confinement. In a case of chronic inversion described by Professor Blair Bell a nulliparous patient, seven years after the menopause, had had bleeding for six weeks. A necrotic, fibromyomatous polypus protruded through the vulva, which was removed with scissors. The pedicle consisted of the inverted, senile uterus, on the apex of which was situated the tumour. Laparotomy was performed and the uterus and appendages were removed, with complete recovery of the patient. The importance of the spontaneity of the inversion and fundal attachment of the placenta or tumour was emphasized in the description.

Professor MILES H. PHILLIPS (Sheffield) was of the opinion that in acute inversion the uterus should not as a rule be replaced at once.

Dr. M. M. DATNOW (Liverpool) showed a specimen of primary ovarian pregnancy in which Spiegelberg's criteria had been fulfilled. He showed also a calcified dermoid, which as a parasitic cyst had caused no symptoms.

Reviews.

THE MEDICAL ANNUAL, 1930.

THERE can be few medical publications in the English language that are so widely read as *The Medical Annual*.[1] It appeals to the general practitioner, who wants a compact review of the latest works on diagnosis and treatment; it appeals to the specialist, who wants to keep in touch with advances in departments of medicine and surgery other than his own; it is, moreover, one of those delightful books that, once taken up, are difficult to put down again.

The current volume is full of interest. Dr. Geoffrey Hadfield contributes a well-written article on the subject of nephrosis. He considers that the tendency at present is to regard this condition as a slowly evolving type of nephritis rather than as a general metabolic disorder. The main practical outcome of the controversy is the clear necessity for allowing oedematous cases of Bright's disease much larger quantities of protein than has been customary in the past—provided that they can utilize it without retaining nitrogen. Dr. Robert Hutchison gives a brief account of the intestinal flora, and the part played by diet in determining the relative proportions of the different organisms composing it. Nothing, he wisely points out, has emerged from experimental work of late years to give any support to the view that, as the result of bacterial action in the intestine, poisonous substances are elaborated which by their absorption gain access to the tissues and lead to chronic intoxication. He likewise deprecates the prevalent, and largely unjustifiable, administration of vaccines prepared against normal inhabitants of the intestine. The surgical treatment of gastric ulcer is a never-failing subject of interest. Mr. Rendle Short unhesitatingly recommends partial gastrectomy. For duodenal ulcer he advocates destruction by the cautery, together with removal of the appendix. That elusive term "puerperal morbidity" continues to evade definition, and its etiology remains obscure. A certain proportion of severe infections seems to be referable to *Streptococcus pyogenes*, but it is clear that fever in the puerperium may often occur in the complete absence of this organism. The infectious fevers are dealt with very thoroughly by Dr. J. D. Rolleston. He is convinced of the value of antitoxic serum in the treatment of severe, especially septic, cases of scarlet fever, and points out that it may lead to a striking improvement in the general condition without an immediate fall of temperature to normal. It is a pity that all reference to the modern method of performing the Widal reaction has been omitted, and that no mention is made of the significance of O agglutinins in the serum of inoculated patients. Colonel Lister deals with affections of the eye; we can find in this section no description of "pink eye," which has prevailed in epidemic form in parts of Europe during the past year, and which has often proved so refractory to treatment. Dr. W. H. Wynn discusses the value of sanocrysin in the treatment of pulmonary tuberculosis, and concludes that it is of most value in the early exudative type of case. In acute pulmonary tuberculosis sanocrysin alone has but little effect, but when combined with artificial pneumothorax it gives most encouraging results. Mr. Geoffrey Jefferson's critical articles on the surgical treatment of trigeminal neuralgia are of very real value in pointing out the necessity of differentiating between the various classes of patient; cases of post-herpetic neuralgia may experience no relief from operation, while cases of atypical neuralgia are invariably made worse. Mr. Thurstan Holland contributes a section on *x*-ray diagnosis, which deals with a number of different conditions; it is interesting to note that, apart from rare exceptions, all radiographical circular shadows appearing in the lung areas are indicative of cavitation. The author of the section on animal diseases communicable to man has made a commendable attempt to use the new bacterial terminology. Apart from small slips, such as the misspelling of *Pfeifferella* and the assigning of a masculine

[1] *The Medical Annual*. Forty-eighth year. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1930. (Demy 8vo, pp. c + 650; 130 figures; 61 plates. 20s. net.)

gender to *muriseptica*, he has made one serious mistake—namely, that of allocating *Corynebacterium diphtheriæ* to the *Clostridium* group, or group of spore-bearing anaerobes, a group to which it has no affinity whatever. The volume is a credit to the care and industry of the producers, and the numerous illustrations it contains add greatly to the value of the text.

PHARMACOLOGY AND THERAPEUTICS.

THERAPEUTICS, Pharmacology, and Materia Medica[2] by Dr. FRANÇOIS ARNAUD, professor of medicine at Marseilles, is one of the best French textbooks on this subject that we have seen. The author's aim has been to give a systematic account of the science of therapeutics, based on a rational plan, and in pursuit of this aim the drugs are classified according to their use. This method of approach is familiar in Britain, but is a striking advance on the method still frequently adopted in French textbooks of classifying the vegetable drugs according to the natural orders of the plants from which they are derived.

The volume is of substantial size (878 pages), and in the case of each drug sections are devoted to the materia medica, pharmacology, therapeutic uses, and methods of application. A comparison with standard English or American textbooks on the same subject reveals certain interesting differences. The methods of administration of drugs are treated very thoroughly, and in this respect the book is superior to most textbooks of a similar size in our language. The number of drugs described is large, and an amount of space that seems rather excessive is devoted to drugs that are generally regarded as of secondary importance. The treatment of the purely pharmacological aspect of the subject is not satisfactory. Apparently French authors do not recognize many facts that are in this country regarded as completely established. For example, alcohol is classified as a central nervous stimulant, bromides are stated to be excreted almost completely within thirty-six hours, and adrenaline is stated to stimulate the intestinal muscle. This divergence in pharmacological outlook is reflected in the discussion on the therapeutic uses of drugs. Little distinction is made between the action of digitalis on hearts with normal rhythm and its action in auricular fibrillation. Ergot is recommended for the treatment of haemoptysis and pneumonia. It is stated that pituitary extract can be given by mouth, though hypodermic administration is mentioned as being preferable.

The accounts of the history of the subject show an amusing difference from those usually given in textbooks written in English or German. For example, in the history of insulin no mention is made of the work of Minkowski, and the work of Banting and Best is represented as a continuation of the work of Lagnesse, while the subsequent development of the clinical application of insulin is attributed chiefly to French workers. The book reveals, indeed, in a somewhat striking manner, the fact that French pharmacology has, during the present century, developed in a curiously insular manner. All standard textbooks on pharmacology in English or German show a large measure of agreement regarding the fundamental facts of the subject, but French authors seem to pay relatively little regard to pharmacological work done outside their own country during the present century.

BILIARY DISEASE.

THE *Munchener medizinische Wochenschrift*, a well-known weekly medical journal in Germany, has recently published short series of clinical lectures by different writers, and the course on diseases of the liver and bile ducts was entrusted to Professor LEPEHNE of Königsberg. The choice is excellent, since the author is one of the best known of the younger German workers in this branch of clinical medicine. Lepehne's lectures[3] have now been published as a short book of about 150 pages, at the modest price of six marks (bound). As would be expected from a man of Lepehne's ability as a research worker on several aspects of hepatic disease, the lectures are scientific, and take note of all the recent advances from America, Great Britain, and Holland. Being addressed particularly to practising physicians, however, all methods of value in diagnosis and all modern methods of treatment are fully described. If there is not much which can be abstracted here from this little book, it is only because it follows so closely and systematically the modern trend of opinion on hepatic and biliary disease. One method of treatment advocated for cases of severe hepatic damage (acute hepatitis, acute yellow atrophy, cirrhosis, etc.) is probably unfamiliar to many British readers. The value of glucose in hepatic disease is, of course, now well recognized, but Richter and Umber in Germany have claimed greater success from insulin and glucose combined, so as to fix a large quantity of glycogen in the liver and protect the glandular cells. In this treatment 20 to 30 units of insulin may be given daily along with 30 to 40 grams of sugar, and the dose of each may even be increased. In cases of catarrhal jaundice (hepatitis) the icterus disappears with great rapidity when this treatment, to which Lepehne fully subscribes, is adopted.

MOSQUITOS OF NORTH AMERICA.

THE literature dealing with the culicidae accumulates with such rapidity that a periodic stocktaking is essential to the student who wishes to keep abreast of the subject. Thus it is that *A Handbook of the Mosquitoes of North America*,[4] by ROBERT MATHESON, makes a timely and welcome appearance. In seven chapters of some 260 pages in all, the book presents a clear, summarized account of two-thirds of the 123 species recorded from this region. To the more comprehensive works of Howard, Knab, and Dyar, *The Mosquitoes of North and Central America and the West Indies* (1912–1917), and of Dyar, *The Mosquitoes of the Americas* (1928), it will serve as an admirable introduction.

The first chapter deals with the well-known facts of mosquito morphology, on the intelligent understanding of which depends the success of the student in unravelling the intricacies of systematics. The biology of mosquitos and the range of variation in their habits are discussed in Chapter II. The next chapter is devoted to the relation of mosquitos to disease, and an excellent map is provided showing clearly the endemic areas of malaria in the United States. *Anopheles quadrimaculatus*, *A. crucians*, and *A. maculipennis* are the chief vectors. In Canada endemic malaria is unknown. Brief reference is made to the recent experimental transmission of yellow fever by Bauer by inoculating monkeys of the genus Macacus with the crushed bodies of infective individuals of six species of Aedes and one Eretmopodites. The problem of mosquito control forms the subject of Chapter IV. The methods described are all well known. The question of the repellent effect of species of Chara and Phyllotria to ovipositing mosquitos, which the author has himself investigated, is still *sub judice*. Much intensive research remains to be done on the feeding habits of culicine larvae before our knowledge of the efficacy of stomach poisons is established on a satisfactory basis. The chapter on the study, collection, and preservation of mosquitos will prove useful to the general student, who may do much to advance our scanty knowledge by making accurate observations of the feeding habits and hosts of the adults.

The final and greater part of the book is devoted to systematics of the Anophelini and Culicini. Of the former tribe 8 species are described; of the latter there are descriptions of 73 species belonging to 9 genera. Annotations of the distribution and breeding habits, where known, are appended to each species. The book is well illustrated by twenty-three text figures and twenty-five plates. There is also a useful general index.

MEDICAL MICROBIOLOGY.

THE production of textbooks on bacteriology in Italy has hitherto been on a very modest scale; and it has been intermittent and inadequate to the needs of Italian students. This is attributed by Professor SANARELLI, in the preface which he contributes to Professor VITTORIO PUNTONI's manual of medical microbiology,[5] to the limited circulation of Italian scientific books. Students have, in consequence, necessarily had recourse to foreign books; and in these, Sanarelli complains, the work even of the best Italian observers is rarely appreciated at its true value, and is often overlooked altogether. The publication of Puntoni's work, which does honour to the Roman school of microbiology, removes this reproach. In a brief historical introduction the author refers, with some evident national pride, to the contributions of Italians in founding the science of microbiology. It was Spallanzani who demolished the theory of spontaneous generation, which was seriously obstructing the progress of the science; and the first conception of the pathogenic specificity of micro-organisms is due to Agostino Bassi. Bassi not only discovered the microbe of silkworm disease, but appreciated the main points of the epidemiology and prophylaxis of the disease, including antisepsis. Of Puntoni's book it may be said that it forms a reliable guide to the whole subject of medical microbiology, including the general technique and the special investigation of bacteria, fungi, protozoa, and ultra-microscopic organisms. The list of organisms included in the work is very complete, and their properties, including the phenomena of immunity and allergy, are described with great clearness; and the illustrations are good and well chosen. The book is evidently the outcome of the author's own observations, and is in no sense a mere compilation, although the observations of other workers receive full recognition. It is an excellent and practical manual.

NOTES ON BOOKS.

THE useful and clearly written little work, by Drs. JOHN GUY and G. J. I. LINKLATER, on *Hygiene for Nurses*,[6] which is drawn up in accordance with the syllabus issued by the General Nursing Council, is divided into two parts. The first deals with the communal aspects of hygiene, such as water, ventilation, heating, lighting, sewage disposal, communicable diseases, and external parasites. The second part is devoted to the personal aspects of hygiene, including a consideration of food, clothing, mental and physical exercise, and the relation of the nurse to public health. Appendixes contain an account of the activities of the Scottish Board of Health, as well as the list of notifiable diseases and the composition of various foods.

The fourth volume of the thirty-ninth series of *International Clinics*,[7] of which the first three were noticed in our issue of December 7th, 1929, p. 1060, contains, like its predecessors, a number of attractive and well-written articles on a great variety of subjects. The first five papers emanate from the Fitzsimons General Hospital of the United States Army, and are devoted to the treatment of pulmonary tuberculosis by heliotherapy, artificial pneumothorax, phrenicectomy, and other surgical methods. A section entitled "Diagnosis and Treatment" includes papers on the home treatment of diabetes, the surgical aspects of chronic ulcerative colitis, and the importance of a scientific foundation in mental hygiene. In the section on surgery the papers deal with the surgical physiology of the phrenic nerve, the injection treatment of varicose veins, the diagnosis and treatment of hernia, the history of thoracic surgery, the complications of extrapleural thoracoplasty, the anterior abdominal incision, radium therapy of cancer of the rectum, and the surgical treatment of pulmonary tuberculosis. The final sections, entitled respectively "Medical Questionnaires" and "Medical Trend," contain a heterogeneous collection of short crisp articles on such topics as the treatment of burns, prevention of measles, recent work in undulant fever, the nature of exanthematides, the biological diagnosis of pregnancy, the control of rheumatism, the use of leeches in present-day treatment, the Mayo Clinic and Foundation, the Pan-Pacific Surgical Conference, and many others, eminently suited for busy practitioners who wish to keep their reading up to date.

Halcyon, or the Future of Monogamy,[8] written on prophetic lines like Bellamy's *Looking Backwards* and H. G. Wells's *War of the Worlds*, is an extremely clever addition to the To-day and To-morrow Series. Beginning with an account of the present-day trend of public opinion about sexual matters, the author, Miss VERA BRITTAIN, who has a keen, not to say sarcastic, eye for our inconsistencies, pictures the future, as described in "The History of English Moral Institutions in the Nineteenth, Twentieth, and Twenty-first Centuries," by Minerva Huxterwin, Professor of Moral History in the University of Oxford, and a *soi-disant* kinswoman of Edward Westermarck, author of "The History of Human Marriage." In the second of the chapters quoted from this book written in the middle of the twenty-first century, the "Period of Sexual Reform (1930–1975)" is described, and this is followed by the third chapter on "Scientific Progress (1950–2000) and its relation to the Moral Revolution." The last chapter on "The Triumph of Voluntary Monogamy (2000–2030)" refers to the benefits resulting from the universal knowledge of birth control, the Married Women's Independence Act (1949), and other Acts. Thus early and happy marriages between those of similar ages became common and venereal disease negligible. This vigorous advocacy of birth control, sex instruction, and trial marriages will arouse much thought and, no doubt, strong opposition.

DR. DAVID YELLOWLEES's little book entitled *Psychology's Defence of the Faith*[9] is based on a course of lectures delivered at a conference of the Student Christian Movement, held at Swanwick last summer. The author's main purpose is to consider what psychology has to do with religion, and to indicate and discuss some of the psychological factors connected with religious belief and its development.

PREPARATIONS AND APPLIANCES.

AN ADJUSTABLE HEAD MIRROR.

MR. O. POPPER, F.R.C.S.Ed. (London, W.), writes: The instrument here illustrated was shown at a recent meeting of the Section of Laryngology of the Royal Society of Medicine. Although designed mainly for the nose, throat, and ear surgeon, this mirror may be found useful in other departments of surgery where one is operating on deep parts (rectum, cervix, etc.), where a strong beam of light is essential, and where it is necessary to alter the direction of the beam frequently during the operation. The illustration is self-explanatory. The direction of the beam is adjusted by means of the detachable wire spring handle, which has been previously sterilized, and then inserted with the surgically clean hand into the socket on the

back of the mirror casing without manual contact with the latter. The mirror can now be moved with ease and safety, and with due regard to asepsis. In spite of the bewildering array of headlights, the mirror remains the most efficient as well as the cheapest and most certain form of illumination.

The illustration also shows the handle in the reverse position, where it occupies very little space. I believe this handle to be preferable to the clothes peg generally employed, in that it never slips, does not occupy any reflecting surface of the mirror or injure the latter, and that it is always carried (reversed) on the mirror. It adds very little to the bulk or cost of the instrument. The makers are Messrs. Mayer and Phelps of New Cavendish Street, W.1.

TWENTY-FIVE YEARS IN SURGERY.*

BY

L. R. BRAITHWAITE, F.R.C.S.,

HONORARY SURGEON, LEEDS GENERAL INFIRMARY; DIRECTOR OF SURGICAL RESEARCH, LEEDS UNIVERSITY.

THERE comes a time in the course of every adventure when one stands to gaze backwards on the path he has already trod and forwards to what may be to come. I think there need be little excuse that one who has completed twenty-five years as a student in surgery should in such a manner hesitate, contemplate, and formulate. Inevitably an address of this kind is egotistical, but it must be understood that almost every opinion expressed has been moulded as much by one's association as by one's own experience.

The questions one first asks oneself are: "Has it been worth while?" and "Would you do it again in the same way?" I can answer that it has been well worth while, and that I would do it again in a different way. I would do everything better. I can say with entire honesty that I have done nothing perfectly; as has been well said, "An ideal is for pursuit, and not for capture." It is my conviction that in no other work can such variety of interest be found, such sympathy be created, and such gratitude be won.

In any attempt at a retrospect of twenty-five years in practice I cannot begin without acknowledging the very deep debt I owe to my early master and teacher, the late Edward Ward, and to my very close friend and colleague Lord Moynihan. These two men beyond all others have been my inspiration. I must also say that without the constant affection, confidence, and sympathy of those who have trusted me I could not have carried on with that happiness I have always had in my work. Comedy and tragedy have come to me as to all of us: comedy to lighten the burden of our responsibility, and tragedy to test our endurance and our faith. No one could be more sensitive to tragedy than I am, and there have been times, many times, when I have wondered whether I could or ought to go on—when I have lost assurance in my skill, my patience, or my strength.

I came into surgery at a time when the abdomen was beginning to take the foremost place—a place still, I think, in advance of that of any other branch of surgery. Bland-Sutton and Arbuthnot Lane were the big men in London: Jessop and Mayo-Robson in Leeds. That brilliant star Moynihan was just flashing into his supreme place in the "surgical sky." Operations in the abdomen were becoming commonplace, but still were attended by a high mortality, and were certainly followed by very painful and tedious convalescence. I remember abdominal sections completed by filling the abdomen with a solution of weak carbolic acid and inserting four gauze drains, one into each of the abdominal quadrants. These were also the days of the Bantock's pelvic glass drainage tubes, a prolific source of worry, of pain, and of post-operative adhesions. This was also the time of suppurating bones and joints, especially of the spine. One of my most vivid recollections is of the multitude of such cases appearing for dressing and of the prevalence of lardaceous disease. Gone indeed are all these, just as that very common medical disease chlorosis, which flooded the out-patient room, is gone.

Probably next to the war—that sterile chasm blasted across our path of progress—the most important change in the profession has been the passing of the National Health Insurance Act. This Act has, I think, been a help to most doctors. It has had no material effect on hospital practice, and has, in the main, been of service to the patients.

Reflecting on what has been achieved, my thoughts spring at once to the introduction of x rays and of radium. These two, the most marvellous advances in surgical science of our time, have revolutionized our work, and we have not yet seen the best of either. I remember the beginning of the radium epoch twenty years ago—its early promise, its early decline; and now we are fortunate in seeing its resurrection in a form so gigantic that it bids fair within the lifetime of all of us to eclipse in usefulness everything that surgery has given to humanity—excepting the work of Lister, whereby alone radium is so far capable of being put to its effective use. When I remember those surgical masterpieces of my early teachers—the exquisite dissections of mouth, tongue, and neck, associated as they were with mutilations so abhorrent—I view to-day with a very special gratitude the marvellous results achieved with radium, especially as I never had the skill or the courage to deal adequately with malignant disease in this particular area by the usual operative means.

It follows when one has reached a "milestone" that he can take stock of each particular branch of his work and formulate on it definite views. It is possible that the views I have formulated may be of interest to you. What operations do I think right in each case? What do my colleagues who have to live with them afterwards tell me about the ultimate results? I propose to tell you these things as briefly as I can.

Chronic Appendicitis.

I will begin with the commonest abdominal condition we see—appendicitis. One fact stands out beyond all others, and that is the sooner an operation is done when acute appendicitis is diagnosed the better. I would like to omit the term "subacute appendicitis" altogether. I would include it with acute. Chronic appendicitis is the most difficult abdominal condition to diagnose *correctly*. Most cases diagnosed as chronic appendicitis are tuberculosis of the ileo-cæcal glands, or, more rarely, are renal or ovarian troubles. Some are due to the drag of a big cæcum, part of a condition of abdominal ptosis. Twenty-five years ago no single case of tuberculous ileo-cæcal glands was diagnosed or operated upon in the Leeds Infirmary; last year 37 were operated upon. Pelvic appendicitis, a very serious condition because so difficult to recognize unless the rectum be examined, has rightly come to occupy a definite place in our teaching and in our nomenclature. In 1904 the cases of acute and recurrent appendicitis operated upon at the Leeds Infirmary numbered 137; last year no fewer than 204 were operated upon. Of the former 14 died, of the latter 32 died. It is probably true to say that more lives have been saved by early operation on cases of appendicitis than in all other abdominal diseases.

Gall-stones.

Operations for gall-stones are no light matter: first, because there is still an appreciable operative mortality even in simple cases, and, secondly, because there are far too frequent recurrences. Removal of the gall-bladder does not preclude the re-formation of stones, and while realizing that stones may be left behind in the bile ducts, I am of opinion that this alone does not account for the frequency of recurrence. It is said that the recognition of a small stone in the common duct is an easy matter. I have found it one of the most difficult things I have to do.

I do not believe in operations for gall-stones after one attack. In my opinion exercise, dieting, and treatment by drugs (the best of which is hexamine glycocholate) offer a good chance of permanent cure. Such a line of treatment should, of course, follow every operation done for gall-stones, realizing that the basal cause (probably an increase in blood chole-terol) is still to be dealt with.

I have come more and more to the view that in many cases where the gall-bladder is in good condition, and where well-marked pancreatitis exists, the proper operation is removal of stones followed by a cholecysto-duodenostomy. I do not think removal of a gall-bladder, even a fairly healthy one, does any harm, but it is a more serious operation than cholecystotomy or cholecysto-duodenostomy. It may be one of the most difficult as well as one of the most dangerous of all abdominal operations.

I believe in removal of the appendix as a preliminary part of an operation for gall-stones, on the supposition that it is an organ likely to give trouble, and also because it may be the source of that low type of infection of the biliary tract apparently necessary with other things to the formation of stones. In 1904 there were 45 operations for gall-stones in the Leeds Infirmary, 7 of which were fatal. Last year there were nearly 200 such operations, and 30 of the patients died.

*An address to the Huddersfield Medical Society.

Gastric and Duodenal Ulcers.

I have a more personal interest in the surgical treatment of gastric and duodenal ulcer than in any other condition, and you will expect me to have definitely crystallized views.

In 1904 not a single case of duodenal ulcer was operated on under that name in the Leeds Infirmary, but there were 69 patients with gastric ulcer, of whom 11 died. Last year 89 patients with simple gastric ulcer of all kinds were operated upon and 15 died, while no fewer than 216 cases of duodenal ulcer of all kinds were operated upon, with only 23 deaths. Of these patients no fewer than 107 had perforated ulcers, and 19 died.

I am of opinion that gastric and duodenal "ulcers" are appearing and disappearing in most of us. They begin as erosions of Peyer's patches, and are due to infection by lymph stream from the intestinal tract, probably the ileo-caecal angle. Every attack of serious indigestion means one erosion or more; every cure of such an attack means the healing of an erosion. I would call an ulcer an unhealed erosion—unhealed because its situation makes it liable to injury and incapable of rest, and because of some quality in the gastric juices of which we really know very little. Certainly it is not a matter of hyperacidity alone. I think the presence or absence of bile is an important factor.

I believe in the cure of an early gastric or a duodenal ulcer by medical means; but they are not all cured. Can I lay down any time limit when surgery should step in? And when surgery has stepped in, what of the future? We all know those distressing acute ulcers which perforate or bleed. These ulcers have been held up as a reason for early operation, but we have not yet arrived at a stage when we are capable of diagnosing them. They are frequently without symptoms. Certainly such acute ulcers are very rarely found by *x*-ray diagnosis, and other methods of investigation have been singularly unhelpful. The Rehfuss and other stomach contents tests have been disappointing in my experience. I have come to the conclusion that any ulcer clearly shown by *x* rays will not disappear permanently and fully except as a result of operation. Obviously perforation needs operation; but does haemorrhage? One haemorrhage does not, but two haemorrhages do. When I operate for perforation or for haemorrhage I like to do something to try to ensure the cure of the ulcer.

Treatment of Duodenal Ulcer.

I do not think we can discuss the treatment of duodenal and gastric ulcer in conjunction. They are, in my view, as different in their treatment as in their symptomatology. To take duodenal ulcer first, there is little doubt that the early symptoms of the chronic ulcer are those of hyperchlorhydria, a vague term indicating relief of symptoms by alkalis or by food. In my opinion treatment by Maclean's alkali method—really nothing more than we did when I was a student, except that Maclean makes it intensive—is the right method to pursue, remembering that regularity and appropriate meals, adequate exercise and mental peace, and removal of septic foci, are essential to success. I would suggest that medical treatment should go on for twelve months, but an *x*-ray examination should be made much earlier. The essential features of medical treatment are persistency and regularity.

I think very few duodenal ulcers are found on *x*-ray examination. Distortion of the duodenal cap and pyloric stenosis with increased gastric peristalsis are the usual findings. If these are found, or if the crater of an ulcer is seen, then I think operation should be undertaken. In the absence of any *x*-ray findings, if the symptoms are persistent and worrying, I should advise operation after twelve months' medical treatment. One can afford to wait if the patient will submit, because malignant disease practically never occurs.

The question of what operation shall be done is still a matter of controversy. Experts in radiology tell us that the best results are those where a short-circuit opening is a very small one, in fact where nothing appears to go through from the stomach, and only intestinal contents regurgitate. If this is a fact we should indeed pause and think whether gastro-jejunostomy is the right operation. An appreciable percentage of duodenal ulcer operations is unsuccessful. They relieve; they ensure by suture of the affected area that perforation, and probably haemorrhage, shall not occur; but they replace one kind of indigestion by another not so bad and not so dangerous. In addition they sometimes render the patient liable to unexpected high intestinal dyspepsia with diarrhoea coming on for no apparent reason immediately after the ingestion of innocuous foodstuffs. Occasionally the duodenal ulcer is replaced by a jejunal ulcer, a very much more serious matter.

I have definite views on the operative treatment of duodenal ulcer. I would, of course, remove the appendix, and burn out and suture the ulcer area, but would prefer a gastro-duodenostomy to a gastro-jejunostomy. This operation has been strongly advocated by my colleague Mr. Flint, and I have practised it whenever possible. Why should a gastro-duodenostomy be preferable? I think because it allows a better reflux of duodenal contents into the stomach—a reflux we know to take place towards the end of digestion in normal health. In addition, it allows food to remain in the stomach for the purpose of digestion longer than a gastro-jejunostomy does.

Treatment of Gastric Ulcer.

Now gastric ulcer is entirely different. I do not agree that gastric ulcers are *very* liable to malignant degeneration, but I have often seen this happen, and I feel, therefore, for this reason, and because gastro-enterostomy is rarely satisfactory in my hands, that the proper operative procedure is partial gastrectomy. Medical treatment should be as for duodenal ulcer, but it is easier to get an *x*-ray picture of a gastric ulcer, and when an ulcer is diagnosed by this means, in my opinion it will not heal *permanently* by any other than operative treatment. I do not mean that every ulcer can be diagnosed by *x* rays, but it is not my practice to operate for gastric ulcer in the absence of a positive *x*-ray report. I recognize that MacLean claims definite cures of both gastric and duodenal ulcer by the intensive alkali treatment. Such cures he supports by *x*-ray evidence. Neither my medical friends nor all my surgical colleagues can claim similar success by the same means applied in the same way.

Now although partial gastrectomy is the operation for gastric ulcer, and gives, I think, better results than gastro-jejunostomy for duodenal ulcer, the operation may be very difficult and is dangerous; it may even be impossible. In the latter circumstance excision of the ulcer with a gastro-enterostomy is most favoured, though I myself have done a large number of cholecysto-gastrostomy or gastric bilification operations, with results which have gratified me in the main. Merely to excise either a duodenal or a gastric ulcer is not enough; the disordered physiology of the stomach has to be repaired if recurrence is to be avoided.

In both gastric and duodenal cases the "cure" does not finish with the operation; I do not think it ever finishes. The patients must go on all their lives taking care in their habits and their diet. The abuse of smoking has been considered an important factor in both gastric and duodenal ulcer. I am of opinion that moderate smoking is not deleterious, but I am in the habit of prohibiting abuse.

Miscellaneous Operations.

I have been almost consistently disappointed with my work on malignant disease, excepting that of the breast and large intestine. I do not advise early colotomy for carcinoma of the rectum in the absence of the possibility of cure of the disease.

My prostatic work has been successful. The introduction of an almost routine two-stage operation has lowered the mortality in private practice very markedly, though it is still too high for my happiness. In infirmary practice, however, last year twenty-eight patients were operated upon by the one-stage operation and seven died, whereas of twenty-three operated upon by the two-stage operation only three died.

For some years I was in the midst of short-circuiting and resection for abdominal ptosis, particularly of the large intestine. I am glad to say I never did either

myself. I know the results were not good, and these operations have almost ceased to be performed at Leeds. It is, however, only fair to say that there are still surgeons who would have us continue on the old lines.

Outside the abdomen, operations on the thyroid and hernia operations remain about as they were when I began, with much the same good results. A great advance has, however, been made in the surgical treatment of exophthalmic goitre.

It has been said that surgery has gone as far as it can; that it is as perfect as it can ever be. I do not agree with either view, and most certainly not with the latter. I would instance the mortality from pulmonary and cardiac embolus in patients who are apparently first-class risks; nothing has been done to combat successfully this, our biggest risk and most dreaded catastrophe. I believe there are yet bigger fields to conquer and better plans and material to be found for the campaign. The perfect anaesthetic is yet to come, and better methods are needed of preventing and dealing with post-operative ileus. Radium is narrowing the field, for it is taking away from us the most unproductive and disappointing of all our efforts; but what a vast deal remains to be done, particularly in dealing with gastric and duodenal ulcer, gallstones, and enlargement of the prostate.

Conclusion.

A great deal has been done to popularize spinal anaesthesia. High spinal anaesthesia has never been accepted, while various kinds of local anaesthesia combined with general have had, and are having, their day. Intratracheal, intradermal, intravenous, and rectal general anaesthesia by all kinds of methods and machines have heralded a "perfect" anaesthetic. Nitrous oxide, oxygen, and carbonic acid gas have had their place in the procession, while drugs like scopolamine, morphine, hedonal, avertin, and a host of others, have been hailed with acclamation. Ether and chloroform have been always with us, and I think stand unrivalled. Methods of administration have changed in bewildering fashion, but the greatest improvement has undoubtedly been the conditions under which anaesthetics are given. The preliminary hypodermic of scopolamine and morphine, the absolute quietude and semi-darkness of the surroundings, the initiation by nitrous oxide followed by ether—all these things have indeed made an operation a much less terrible business than it was twenty-five years ago.

I have realized after all these years that one may have skill, courage, perseverance, and power, but more than these is essential. An understanding mind and a sympathetic spirit constitute the priceless asset. These two qualities come to most of us only after years of practice. They largely constitute what is meant by "experience." These two things a patient, driven as he is to distraction by fear and doubt, will move heaven and earth to find.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

BIENNIAL DINNER.

THE biennial dinner of the Royal Society of Tropical Medicine and Hygiene was held at the May Fair Hotel, London, on May 22nd, with the president, Dr. G. CARMICHAEL LOW, in the chair. When the loyal toasts had been honoured, the chairman expressed the society's thanks to Sir John Rose Bradford, P.R.C.P., for taking the place of the Marquess of Reading, whose health had prevented his attendance.

Sir JOHN ROSE BRADFORD, proposing the toast of "The Society," said that medicine as a whole had three functions: to relieve, to cure, and to prevent; the last was the greatest. Tropical medicine was a branch of medicine as a whole, and had faithfully served the highest objects of medicine. No other branch of medicine had during the last fifty years produced such striking results, and tropical medicine should be justifiably proud of its record. Its work was recognized by the commercial world, the industrial world, and the Government. An extraordinarily important part in the development of tropical medicine had been played by British workers. It had been well said that Great Britain produced great men in medicine, but did not always appreciate the greatness of the men she produced. One reason for the remarkable development of tropical medicine was its close association with the ancillary sciences, particularly zoology, and one of its attractions was the possibility of combining exact clinical and exact scientific work. One way of showing appreciation of the great men who had been members of the society would be to provide it with a suitable home.

The PRESIDENT, in reply, mentioned the work of Sir Patrick Manson and of Sir Ronald Ross, and enumerated some of the other leaders in tropical medicine and hygiene who had been members of the society since its foundation in 1907. The proposal to build a house for the society was a matter which he had deeply at heart, but a great deal more money was needed before the "Manson House" could be opened. Dr. Low paid a tribute to the work of the officers of the society, particularly Miss Mildred Wenyon. He visualized the society in its new home as the head of tropical medicine for the whole world—a society which would institute re-search, discuss imperial problems, and have meeting rooms where these returning from the Tropics could get into touch again with medicine and home.

Dr. P. MANSON-BAHR, proposing the health of "The guests," regretted the absence of Dr. Drummond Shiels, M.P., a pillar of strength in work, war, politics, and play, and Sir James Michelli, treasurer of the Seamen's Hospital Society. Likening the gifts of the society's guests to those of an international football team, he paid compliments in turn to Sir John Rose Bradford, Lady Manson, and Mrs. Albert Chalmers; Lieut.-General H. B. Fawcus, Director-General A.M.S.; Surgeon Vice-Admiral Gaskell, Medical Director-General R.N., and Air Commodore J. McIntyre, Director-General R.A.F.M.S.; the Editors of the *Lancet* and the *British Medical Journal*; Sir James Maxwell and Colonel Reginald St. Johnson, Governor of the Leeward Islands (both members of the medical profession), and Sir Herbert J. Read, ex-Governor of Mauritius; Mr. Donald Armour, president of the Medical Society of London, Professor Frederick G. Hobday, principal of the Royal Veterinary College, and Sir Basil Blackett, chairman of the Colonial Development Advisory Committee.

Sir HERBERT READ, replying, associated himself with the tribute paid to the memory of Sir Patrick Manson, and agreed that it was impossible to overrate the importance of tropical medicine and hygiene. The death rate among European officials in British West Africa had fallen in thirty years from 70 to 9 per 1,000, and in Mauritius and Jamaica the figures compared not unfavourably with those of towns in this country. Admiral GASKELL, also replying, spoke of the strong and friendly connexion between the society and the Navy. He had been to almost every fourth part of the world which existed, but had not contracted all the diseases which he might have contracted, thanks to the magnificent work of experts in tropical disease. Great Britain needed a strong Navy much as an individual needed personality—to prevent people playing games of bluff—and one of the ways of maintaining the personnel at its very best was the prevention of tropical disease.

Colonel W. P. MACARTHUR, proposing the toast of "The Chairman," said that there was hardly a single major quality desirable in a president that Dr. Low did not possess. In the first place, it was popularly rumoured that he was a Scotsman; and for any Scotsman to join the ranks of an organized body was but a preliminary step to becoming leader of it. Another desirable quality in the president was his wise caution; he could never have found himself in the unhappy position of having to eat his own words. Colonel MacArthur recalled Dr. Low's classical work on filariasis and malaria, and mentioned a paper by him and Manson on the intestinal ulcers of kala-azar. Dr. Low had served the society well in many offices, and in collecting funds his precept followed his own magnificent example. His kindly nature, his honesty of purpose, his sturdy loyalty, and his sense of humour had endeared him to all, and those who knew him best could best testify to the strong leaven of humanity underlying his austere devotion to professional duty and his determination to add still further to his already stupendous list of causes of enlargement of the spleen.

British Medical Journal.

SATURDAY, MAY 31ST, 1930.

PHYSIOLOGICAL FACTORS IN DIABETES.

WHEN in 1904 the late Dr. George Oliver of Harrogate founded a lectureship at the Royal College of Physicians of London to commemorate William Sharpey, one of his chief aims was to encourage the application of physiological knowledge to the prolongation of life. An excellent example of the fulfilment of this purpose is in the use of insulin for the treatment of diabetes—the subject-matter of Professor Macleod's Oliver-Sharpey Lectures for 1930, of which reports have appeared in our issues of May 10th (p. 868) and May 17th (p. 918). Modern medicine has seen many advances in the prevention and cure of disease; but the treatment of diabetes is perhaps the outstanding example of prolongation of life without arresting, or in popular terms "curing," the malady.

In his lectures Professor Macleod described a series of researches which have been pursued at Toronto since the introduction of insulin in 1922. These further researches are of the greatest practical importance in medicine. For example, the behaviour of the depancreatized animals treated with insulin and fed exclusively on meat and fat showed that raw pancreas was required in addition to insulin to enable such animals to live on a diet from which carbohydrates had been excluded. Every now and then a diabetic patient is met with in whom insulin seems insufficient by itself to maintain health. Often, indeed, improvement can be obtained for such cases by increasing the carbohydrate and diminishing the fat and the meat in the diet. It remains to be proved whether some patients in this group would tolerate a fat-rich diet if raw pancreas were administered in addition to insulin. Another problem well worth studying was the effect of pregnancy in depancreatized animals. There was no evidence that the foetal insulin had in any way benefited the maternal organism. This is an important fact, because it has been stated that a diabetic woman during pregnancy might live to some extent on the insulin of her unborn baby, and need smaller doses of insulin. Occasionally, as the lecturer said, this may be possible, but to count upon it exposes both mother and child to grave danger. In lactation it is clear that the blood sugar is depleted to furnish sugar for the mother's milk. Insulin hypoglycaemia is thus a real danger. The remedy consists in adding to the intake of sugar rather than in decreasing the insulin.

Soskin's observations with regard to the failure to use carbohydrate when a large amount of protein is being metabolized demand attention and careful study; and his warning that the antidiabetic power of any remedy must not be judged solely by its capacity to lower the blood sugar in a normal animal cannot be too strongly emphasized. Soskin found that none of the preparations that had been introduced and advertised simply on the ground that they had this capacity could keep a depancreatized animal alive for a long enough period to justify their acceptance as insulin substitutes. Professor Macleod sounded this warning again even more emphatically at the end of his second lecture, when he dealt with synthalin. It was possible, he said, that the effects this substance appeared to have were dependent on the undoubted damage it did to the liver cells, and that, for this reason, it was a dangerous drug to use. He dwelt also on the physiological fact that insulin has a much greater effect on animals previously fed on carbohydrate than on those which have undergone carbohydrate deprivation. This is a valuable clinical point in dealing with those patients who seem to need immense doses of insulin—in other words, with the insulin-resistant type. The immediate application of the facts mentioned in these lectures about the nervous regulation of insulin secretion is not so obvious. At the moment it seems as though stimulation of the vagus increases the secretion of insulin, but that the same nerve may carry inhibitory fibres. However this may be, Professor Macleod regards hormone control as more important than nerve control from a practical standpoint. He indicated other conditions besides diabetes which are associated with disturbed insulin secretion, such as epilepsy, muscular dystrophy, and excessive corpulence or leanness, all of which call for further investigation.

Professor Macleod in these Oliver-Sharpey Lectures has once more demonstrated the fundamental connexion between physiology and medical practice. The teaching hospitals could help to strengthen this tie by appointing to their staffs physiologists who would instruct students in applied physiology and help them to correlate physiology with clinical medicine.

THE FIRST REGISTER OF BIO-PHYSICAL ASSISTANTS.

CERTAIN administrative problems concerned with electrical treatment and actinotherapy have now been before the profession and the British Medical Association for some years. The practitioner has often neither time nor facilities for such work, and it was with this in mind that the Representative Body of the Association, in July, 1928, pointed out the necessity for the registration of competent and suitable lay persons to whom doctors could with confidence send their patients for treatment. Following on the resolution adopted by the Annual Representative Meeting at Cardiff, warning the public of the risks involved in the use of radiation and electricity as methods of treatment by untrained and unqualified persons, the Science Committee presented to the Council of the Association in December, 1928, a report on the practical steps to be taken in the organization of courses of training in these procedures, and the preparation of a roll of persons who had satisfactorily followed such courses. Authority was thereupon given by the Council to the Science Committee to get together a small committee of experts to draw up a syllabus, and details of training and examination, with a view to the issue by an authorized and independent body of a diploma of proficiency in treatment by light, including ultra-violet light, heat, and electricity. This expert committee divided the subject into two parts, and decided that for the present it was desirable that the examination for Part I should be inaugurated so as to give effect to the resolution of the Representative Body. The members of the expert committee, having drawn up general lines of procedure, entered into an arrangement with the Society of Apothecaries of London to institute a register of approved persons under the conditions

which they had laid down. This practicable plan, largely due to the initiative of Professor W. E. Dixon, was reported to the Council and the Representative Body last year; regulations were drawn up, as recorded in our issue of June 1st, 1929 (p. 1012); and we are now able to welcome the publication of the first *Register of Bio-Physical Assistants*.[1] This register contains a history of its inauguration, full details of what is required in order to become a registered bio-physical assistant, a statement of the undertakings which registered persons are required to sign, and the first list of names arranged both alphabetically and topographically.

Radiological authorities have often pointed out the dangers which may follow the improper use of ultra-violet lamps. Many of the lamps on sale emit rays to which man has never hitherto been exposed—that is, which are not present in sunlight. The evidence of the harm they may do is overwhelming. Few of us would dare to have prescriptions containing poisons dispensed by an untrained person, but the dispensers of rays have been, up to now, uncontrolled, unregistered, and not rarely unqualified. It is obviously right that members of the medical profession should have trustworthy information to enable them to distinguish between lay persons who have been properly trained to dispense electricity and rays, and those who have not. At the present time, all kinds of rays are used by charlatans in Europe and America to exploit the public. Barbers employ them, especially for their lady clients; beauty institutes have set up appliances which are generally a harmless fraud, though ultra-violet light has been used in some of these cosmetic parlours; sun-ray institutes are the fashion, and the public is indulging in self-treatment. Some countries have already taken action. The Superior Council of Public Hygiene of France, consulted by the Minister of Hygiene, has declared "that in view of the serious accidents which may result from the use of ultra-violet irradiations handled by incompetent persons, it is necessary, in the interest of public health, to confine the use of these procedures to hospital services, and to authorize their application only by specialist physicians." In the United States the Council on Physical Therapy of the American Medical Association has reported on the danger to the public of incitements to self-treatment by the sale of generators of ultra-violet energy; it points out that undue confidence is reposed in the advertising literature, and that unsuitable cases are often treated, or cases not amenable to treatment.

The British Medical Association has been mainly responsible for the setting up of the *Register of Bio-Physical Assistants*, and we regard it as a first step in the control of the new class of medical technicians or dispensers of physical forms of treatment. It is most important that all such technicians or dispensers should be under the control of the medical profession and their work placed on an ethical basis. We believe that the present register is a valuable means towards attaining this aim, and we therefore appeal to all practitioners, in so far as they are able, to send their patients who require such treatment to properly registered dispensers, with confidence that those holding the certificate issued by the Society of Apothecaries, which entitles them to use the suffix B.P.A., possess the proper skill and training, and are under the control of an ethical code.

CAROTENE AND VITAMIN A.

RECENT work on carotene suggests that we may be on the way to a solution of yet another biochemical puzzle. It is not very long since the demonstration that vitamin D was derived from a sterol, and that its production was the result of the action of short wave-length light on ergosterol, served to clear up a good many difficulties, both clinical and experimental. Several workers have recently published results suggesting that a similar relation may exist between carotene and vitamin A.

Carotene is one of a group of coloured substances nowadays generally known as the lipochromes, because their physical properties in some respects resemble those of fats. They are very widely distributed in nature, and are found both in plants and in animals, though it is likely that the latter do not manufacture them for themselves, but derive them from the ingestion of plant food. Carotene itself is a hydrocarbon of deep red colour, and having the empirical formula $C_{40}H_{56}$. It is obviously an unsaturated compound, and Zechmeister and Cholnoky[1] have shown that it is easily reduced by hydrogen, in the presence of platinum, to a colourless, more saturated body.

The idea that carotene and vitamin A may be related is by no means new, but earlier attempts to establish a relation failed, probably because, as suggested by Moore,[2] the experiments were carried out before vitamins A and D had been differentiated, and the diets used were lacking in both. More recent experiments would seem to make it certain that carotene can replace very fully a pure A deficiency, provided that other vitamins are present. A comparison of the chemical and physical properties of vitamin A and carotene is interesting. Vitamin A must be a colourless compound, since very potent cod-liver oil concentrates are almost colourless, while carotene is highly coloured; vitamin A is freely soluble in alcohol, carotene sparingly so; both compounds give a blue colour with antimony trichloride, but with vitamin A the colour is permanent, with carotene it is fleeting; and the absorption spectra are different. Evidently the two substances are not identical. The questions that have yet to be answered are these: Assuming that there is a close relationship between vitamin A and carotene, is one to be regarded as precursor and the other as product, and, if so, which is which? Are both of them biologically potent, or are we perhaps faced with the troublesome possibility that vitamin A is an extremely potent substance present as an impurity in all samples of carotene so far examined?

Green and Mellanby have carried out a number of interesting observations on the anti-infective function of carotene. Their previous work had shown that vitamin A was capable of protecting animals against infection,[3] and they had produced some evidence of its remedial action in cases of puerperal sepsis.[4] In a recent paper[5] they describe investigations tending to the conclusion that carotene also will protect rats against infections (xerophthalmia, tongue abscess, mastoid infections, enteritis, cystitis, and so forth); and that it will assist the recovery of animals in which infections have developed as a result of vitamin A deficiency. They have obtained these results not only with pure carotene, but with vegetables known to be rich in this substance. Collison, Hume, Smedley-

Maclean, and Smith[6] have shown that there is much carotene in spinach and in the green part of the cabbage leaf; carrots, too, are an important source of this substance. Carotene has been of interest in another connexion. Hypercarotinaemia has long been known to be associated with the yellow pigmentation of the face and palms that sometimes occurs in various pathological states, particularly in diabetes; and its presence has been thought to indicate a bad prognosis. Careful work has shown, however, that the condition has no pathological significance at all; indeed, in diabetic subjects it may be traced to their consumption of a diet containing large amounts of green vegetables.

EPSOM COLLEGE.

THE council of Epsom College has instructed Messrs. Pite, Son, and Fairweather, the well-known hospital architects, to prepare detailed plans and specifications and to obtain tenders for a new school sanatorium of fifty beds, estimated to cost approximately £25,000. It is hoped that the building will be completed in the autumn of 1931. With this decision the programme of improvements and extensions commenced in 1924 and carried on steadily ever since will be concluded except for relatively minor additions. Since that date there have been erected the War Memorial Chapel, a large chemical block, a new games pavilion, and a fine covered rifle range, with numerous other extensions to existing buildings. The erection of the new sanatorium will permit of the present one being turned into an additional house for forty boys, bringing the total number of boys up to 440, and so enabling the admission of at least a moiety of applicants who now have to be declined. Sketch plans of the sanatorium were reproduced in these pages on December 3rd, 1927, and only small modifications have been introduced into the final plans. These follow closely the lines on which the Ministry of Health considers that a model school sanatorium should be built, and the council has received valued assistance from medical officers of other leading public schools in its aim to provide such a building as will meet all likely needs for years to come. Up to date only some £8,000 has been received in response to the special appeal made to the profession: for this the council has to thank generous individual donors, the British Medical Association, the *Lancet*, the medical staffs of a number of hospitals, various societies, and other bodies: it is hoped that still others will help to swell this sum materially, so that the council may not have to draw largely on funds that it is anxious not to deplete. It is still open to a donor of £10,000 to give his own name or the name of any person whom he desires to commemorate to the main sanatorium, and a donor of £5,000 may do likewise to a single block; while a large ward may be named for £3,000, or a small ward for £1,000, and a single bed for £100. All donors of ten guineas and upwards are entitled to votes, proportional to their donations, at the annual elections of foundationers and pensioners, and such donors become life governors of the college. Donations will be gratefully received at the Epsom College Office, 49, Bedford Square, London, W.C.1.

THE LEAGUE OF NATIONS AND DANGEROUS DRUGS.

THE reports laid before the Council of the League of Nations by the Advisory Committee on Traffic in Opium and other Dangerous Drugs afford little ground for thinking that any effectual progress has been made in restricting international commerce in the scheduled drugs to medicinal and scientific purposes. The disclosures in regard to the extent of the illicit traffic are disquieting and disheartening. Egypt has become a nation of addicts; "every village has its heroin victims," we are told, and "they are the youth of the country." Seizures of smuggled cocaine, often under forged labels, to the amount of more than 5,000 ounces, are reported from India, Burma, Malaya, and Hong-Kong. To one firm alone in Mulhouse has been traced the illicit export, in three and a half years, of 6,414 kilos of heroin, 943 kilos of morphine, and 205 kilos of cocaine. In New York, on board a vessel from France, were discovered eight cases, billed as "brushes," which contained 4,800 ounces of morphine and 2,000 ounces of cocaine. Such seizures probably represent only a fraction of the appalling world-wide traffic which is going on in defiance of the terms of the Hague and Geneva Conventions. Moreover, the Advisory Committee affirms that "there still remain important sources of supply and centres of distribution which have not yet been traced." The assembly of the League last September, dismayed by the persistence of the illicit traffic after ten years' efforts to secure its reduction or suppression, called upon the Advisory Committee to proceed without delay to prepare plans for the limitation of dangerous drugs to medical and scientific purposes. It adumbrated the summoning of a conference of representatives of manufacturing and consuming countries for the same purpose, and urged the strengthening of the Advisory Committee by the addition of representatives of non-manufacturing countries. Considering that most of the manufacturing countries have undertaken, in accordance with Article 9 of the Hague Convention of 1912, to enact laws or regulations to limit the manufacture, sale, and use of the scheduled drugs to medical and legitimate purposes only, and to co-operate with one another to prevent other uses of such drugs, the action now resolved upon cannot be regarded as unduly expeditious. Unfortunately neither Turkey nor Persia, large producers of opium, has as yet ratified either the Hague or Geneva Conventions, and continue to afford facilities for illicit exports, chiefly to the Far East. The Advisory Committee, while adverse to an increase of its membership, has outlined suggestions for procedure for limitations of manufacture "which might be adopted for arriving at a solution before the meeting of the conference," which the Assembly of the League desires to convene. The suggestions outlined by the committee cover: "(*a*) the fixation of the total amount of the drugs to be manufactured annually; (*b*) the allocation of that amount between the manufacturing countries; (*c*) the distribution of that amount so as to ensure that each country receives the amount required for its medical and scientific needs." Critics of the Advisory Committee might not unreasonably complain that these questions should have received consideration and been adequately determined during the ten years in which the committee has so laboriously deliberated. It is, however, painfully evident that much remains to be done, and done with zeal and alacrity, if the pious aspirations of the Hague and Geneva Conventions to suppress the abuse of opium and other dangerous drugs are to be internationally achieved.

J. G. ADAMI.

THE memoir of J. George Adami,[1] by his widow, with contributions from various friends, is a concise and cleverly written biographical sketch, which places in a clear light the grounds on which Adami has been properly regarded as a leader in pathology. Among the several appreciations, that by Professor Warthin is perhaps of most interest, as affording what appears to be a very just conception of Adami's position as a pathologist. Adami had little concern for the discovery of new phenomena; he was never a routine experimental investigator. The material with which he worked he found ready to hand in the data and

[6] *Biochem. Journ.*, 23, 634.

[1] *J. George Adami*: A memoir by Marie Adami, together with contributions from others, his friends, and an introduction by Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B. London: Constable and Co., Ltd. 1930. (Demy 8vo, pp. xlii + 179; 1 portrait. 10s. 6d. net.)

phenomena described in the current literature of pathology. In his best-known work—the *Principles of Pathology*—it was not his aim to re-state these data and their classification, but to expound the laws and principles governing the production of phenomena and determining their classification. He sought to give the known facts of pathology a logical significance, through principles derived from deduction and projected against a background of general biology. A profound knowledge of biology rendered him peculiarly fitted for this task, and his work, in its purely scientific aspect, will be chiefly remembered as having left a deep impress upon the evolution of the philosophy of pathology and as forecasting the essential importance of the biological standpoint. It is probable, however, that a feature in Adami's character which is rare among men and which appears to have been the mainspring of his extraordinarily active career—his spirit of universal friendliness and sympathetic attachment to his fellow-men—will have a foremost place in the recollection of those who knew him personally. He loved people and surrounded himself with an environment of outspoken friendship. Interest in others was a special quality in him throughout his life; in youth this had found expression in the support demanded of him by his own family; in student days it is seen in the relationships he maintained with numerous friends, both old and young, for whom no service was too much; and in later life the same friendly interest was displayed towards colleagues and friends. His outlook was never confined to pathology; whatever was human, that had his friendly interest. At his table might be found men of science, of letters, of music, adventurers from the homeland discovering Canada, artists of the new and old schools, men of finance, or ne'er-do-wells. As Vice-Chancellor of the University of Liverpool he took the broadest possible view of his functions; he strove to develop local and civic patriotism, to promote ideals of beauty, intellectual activity, and dignity, whether in architecture, city administration, or in social affairs; to attract the best minds to the city and form a society of the best in all departments of human activity. Of Adami's numerous undertakings the foremost in importance was, perhaps, his establishing the school of pathology in McGill University. In the Dominion, pathology had not been regarded as an individual subject; it had been taught by men engaged in clinical work, and was practically an untouched field. Under Adami's hands the School of Pathology came into being; and he drew round him a group of enthusiastic students, many of whom in after days occupied important posts throughout the American continent.

THE EMPIRE RED CROSS CONFERENCE.

THE delegates attending the British Empire Red Cross Conference, the earlier proceedings of which were reported in last week's issue (p. 968), assembled for their final session at St. James's Palace on May 23rd under the presidency of the Hon. Sir Arthur Stanley. Various subcommittees, to which the consideration of certain matters had been referred, presented their reports and recommendations, all of which were agreed to by the conference. One report had to do with the duties and obligations of voluntary aid detachments. In view of the fact that the scheme for such detachments is designed to supplement the medical services of the naval, military, and air forces of the Crown in every part of the world on general mobilization, the conference placed on record its opinion that wherever somewhat similar schemes were in operation anywhere in the Empire they should follow, as far as local exigencies permit, the general lines of the British scheme, and that in those Dominions and Colonies where no such schemes are in operation consideration should be given to the desirability of inaugurating them. It was further resolved that in order to provide a trained personnel for enrolment in the voluntary aid detachments, steps should be taken to raise and train bodies of men and of women, which, while containing members prepared to assume liability for service under Government, may also include others either undergoing the courses of preliminary instruction or unable for the moment to undertake an official obligation. It was pointed out that the peace programme of the Red Cross needs a large body of workers, who will concern themselves with the improvement of health, the prevention of disease, and the mitigation of suffering throughout the world, and that members of detachments can give valuable personal service to the community in rendering first aid at various public functions, and in assisting at hospitals, orthopaedic and child welfare clinics, and scouts camps, also in helping district nurses and health visitors. The conference, therefore, suggested that in every Dominion and Colony steps should be taken to provide and replenish the personnel of voluntary aid detachments, to furnish a reserve of men and women, if required, in a time of emergency, and to carry out the varied duties incumbent upon a national Red Cross Society. Certain other propositions related to the qualifications for membership of the detachments, the method of training, the uniform (which, it was urged, should be common for the whole Empire, so far as diverse climatic conditions permitted), and the awards, which are to include a long-service medal for fifteen years' service for Red Cross members throughout the Empire. Another series of resolutions concerned the formation of branches throughout the Empire, and the council was asked to set up a committee to co-ordinate the work of Red Cross development in fresh areas, in liaison with the Colonial Office, medical missions, and kindred societies. Methods of obtaining more publicity and a more regular flow of subscriptions were discussed, and it was recommended that an extension fund should be inaugurated for the purpose of starting the Red Cross movement in territories where no such movement at present exists. The help to be given by the Red Cross to victims of peace-time disaster was the subject of another report. The national Red Cross societies were asked to endeavour to persuade their Governments, not so far parties to the international Relief Union Convention—which has been signed by thirty-five Governments—to follow the Governments of Great Britain, India, and New Zealand in giving adhesion. Every national society was also urged to form committees or sections charged with the study of the specific relief measures that may become necessary within its territory, to prepare plans for action in time of emergency, and to establish an organization for emergency relief, capable at short notice of mobilizing the resources of the society both in material and in personnel. One other important work was proposed for the Imperial Red Cross—namely, that every Red Cross unit should develop a service of interpretation and education in the principles which promote health and prevent disease. In Great Britain, it was urged, the Red Cross branches should get into touch with rural community councils, councils of social service, or guilds of help, where such exist, with a view to the closest co-operation with their health committees. A final resolution called the attention of Red Cross societies within the British Empire to the importance of social and economic conditions as factors in the health and welfare of the people, and recommended the establishment of committees of Red Cross societies "to investigate and consider the effect of these conditions upon public health, and to co-operate with other health and welfare agencies in carrying out such investigations and educating the public to the importance of considering economic and social conditions in respect to their effect upon health." It will thus be seen that the Red Cross in peace is attempting an ambitious, if necessarily somewhat vague, programme. In five years' time, when another British Empire Red Cross Conference will meet, presuming no tragic diversion of Red Cross energies to fields of war, these ideas and suggestions will have got more clearly into focus.

ATMOSPHERIC POLLUTION.

THE Department of Scientific and Industrial Research has published the fourteenth report on the investigation of atmospheric pollution which is concerned with observations in the year ended March 31st, 1928. As mentioned in the introduction to the previous report, which concluded the series issued by the advisory committee in association with the Meteorological Office, the department has undertaken to collate the results of local observations on atmospheric pollution, and to carry out research on its nature and measurement. Since the ultimate object of these investigations is to assist public authorities and industrial concerns in dealing with the smoke nuisance and with questions of public health, a standing conference of co-operating bodies has been established to which representatives may be sent by all bodies contributing to research funds or maintaining records. The main purpose of the conference, apart from receiving reports and making recommendations, is to inform the department of problems or difficulties that arise in the course of the work of its constituent bodies. It also seeks to promote the practical application of the knowledge gained. Care has been taken in the present report to simplify the arrangement of statistical information in order to stimulate public interest and encourage the collection of local data. Purification of the air does not appear to have progressed as rapidly as is popularly supposed. Both in London and in Glasgow, for example, little improvement has been observed in the state of the atmosphere since 1922. The total deposit in London during 1927–28 was 316 tons per square mile, while deposits in Glasgow for the same area weighed 320 tons. These results are shown graphically along with curves for sulphate deposits. Particular attention is directed to sulphates and tar as products of combustion. Seven of the eight stations in London reported an increase in deposits of sulphates compared with the general average; nor is any improvement indicated throughout the country. The actual weight of tar deposited per square mile at Salford during the year was 36 tons, and a total of 140 tons of sulphates per square mile was recorded at Burnley. As an indication of smoke pollution the data referring to tar and sulphates are regarded as probably the most reliable, although carbonaceous matter—of which there was a heavy deposit at Newcastle-on-Tyne—is also considered to be very important. The department points out that data will continue to be imperfect unless a considerable number of local authorities and others take part in systematic observations, using standard methods and appliances. Copies of the report, which contains four appendixes, are obtainable from H.M. Stationery Office (3s. 6d.).

METHODS AND PROBLEMS OF MEDICAL EDUCATION.

THE sixteenth series of *Methods and Problems of Medical Education*[1] follows the death, on February 16th last, of Dr. Richard Mills Pearce, jun., its editor from the commencement in 1924. Dr. Pearce was also Director for the Medical Sciences, and as the representative of the Rockefeller Foundation was well known, and will be much missed in this country, which he often visited. The present instalment is devoted to accounts of the departments and institutes of anatomy, histology, and embryology, and contains twenty-five articles describing the teaching arrangements in fourteen countries, in such distant parts of the world as Chile, Japan, India, Australia, New Zealand, and Canada. The three departments in this country of which accounts appear are those of the Universities of Edinburgh and Manchester and of the London Hospital, where anatomical instruction was first given in 1781 by Sir William Blizard, who was, after a considerable interval, followed by such well-known men as Hughlings Jackson and Frederick Treves; the lectureship was held by a member of the staff until 1900, when Sir Arthur Keith was appointed. At Manchester histology, or microscopical anatomy, is taught in the anatomical department, thus agreeing with the American schools, four of which—New Orleans, Cincinnati, Jefferson Medical College, and Tennessee—are reviewed; but in addition Professor Lewis H. Weed of the Johns Hopkins University contributes an article on a plan for a department of anatomy, and Dr. Davenport Hooker shows how anatomy is taught at the University of Pittsburgh in a single correlated course, wherein the development, cytology, histology, and gross anatomy of the various parts of the body are connected up. At the Universities of Otago in New Zealand and of Toronto histology is taught in the anatomical department, as it has been at Sydney since 1923, though there by a special professor. The plans and details of the departments, as usual in these publications, should be extremely valuable and instructive to those about to organize such institutes.

[1] *Methods and Problems of Medical Education* (Sixteenth Series). New York: The Rockefeller Foundation. 1930. (8 × 11, pp. 251; illustrated.)

THE WINNIPEG MEETING: SCIENTIFIC EXHIBITS.

THE committee which is responsible for the organization of the Pathological Museum in connexion with the Annual Meeting at Winnipeg, in August, has issued invitations to members who are proposing to be present to submit specimens, casts, photographs, diagrams, microscopical slides, or other material for display. The honorary secretary of the committee, Dr. Daniel Nicholson, has prepared a form on which advance notification of the nature of such exhibits can be conveniently recorded. Arrangements will be made for the provision of microscopes, if required. As many as possible of the exhibits should be sent, before August 7th, to the Pathological Museum, care of Dr. Daniel Nicholson, Medical College, Winnipeg, Manitoba, Canada. Address cards will be issued in due course. Dr. J. C. Boileau Grant is the chairman of the committee, and it is hoped that a particularly good and representative series of specimens and illustrations will be forthcoming.

LEAGUE OF NATIONS HEALTH COMMITTEE.

AT the recent session of the Council of the League of Nations the Health Committee of the League was reconstituted for a period of three years from July 1st, 1930. The new members of the committee appointed by the Council after consultation with the outgoing committee include Dame Janet M. Campbell, senior medical officer for maternity and child welfare, Ministry of Health, who is chairman of the committee of health experts on infant welfare of the health organization of the League. Sir George Buchanan, senior medical officer, Ministry of Health, has been reappointed a member of the Health Committee on the nomination of the governing body of the Office International d'Hygiène Publique in Paris.

THE May issue of the *Canadian Medical Association Journal* announces that the Royal Society of Canada has awarded to Professor A. B. Macallum, M.D., F.R.S., who retired last year from the chair of biochemistry in McGill University, the Flavelle medal for conspicuous achievement in science, and to Sir Andrew Macphail, M.D., professor of the history of medicine at McGill, the Lorne Pierce medal for outstanding merit in Canadian literature.

THIS year's Morison Lectures, on "Nervous Semeiology," will be delivered before the Royal College of Physicians of Edinburgh by Dr. S. A. Kinnier Wilson on June 2nd, 3rd, and 4th, at 5 o'clock. The Dr. Alexander Black Lecture, on "Folk Medicine in Scottish Ballad Literature," will be delivered by Dr. David Rorie on June 20th, at 5 o'clock.

Nova et Vetera.

THE LIBRARY OF THE MANCHESTER MEDICAL SOCIETY.

BY

E. M. BROCKBANK, M.D., F.R.C.P.,

CHAIRMAN OF THE LIBRARY COMMITTEE.

As briefly announced in the *British Medical Journal* of May 24th (p. 984) the Manchester Medical Society, at its annual meeting on May 7th, resolved to offer to present its very large and valuable library, the largest of its nature in England outside London, to the University of Manchester, and this offer has been gratefully accepted.

The library, like the society, has been in existence for close on 100 years, both having been founded in 1834 through the initiative of Dr. John Hull, gynaecological surgeon. Hull was an unusually well-educated man even for those days, when professional education was based on broader lines than it is nowadays, and he could read Latin, Greek, French, German, and Italian. He was an early advocate of the operation for Caesarean section, and took part in pamphlet warfare on the subject, which was conducted in a personally offensive way by an opponent. He was the first surgeon to use the term "phlegmasia dolens." It was most probably his extensive knowledge and love of books that suggested to him the formation of the Medical Society, just as similar qualities led Thomas Percival to found the Literary and Philosophical Society in the town half a century earlier.

Since 1874 the library has been housed in the Medical School along with books owned by the University, and there the society has also had its reading room and held its meetings. An annual fixed grant in aid of the upkeep of the library, and of its own medical books in it, has been made by the council of the University, the society making up the balance in expense and spending by far the greater part of its income in so doing. But the constantly increasing cost of books and periodicals and of the administration of a library of 50,000 volumes has now got beyond the means of the society, with its limited income, to bear.

Such a decision was hastened by the necessity for further accommodation for its books, and the council of the University naturally asked what guarantee there would be, if it spent a large sum in providing this, that the books of the society would now be moved to a central institution in the town, the formation of which has long been looked upon with very favourable eyes by the local profession. So after careful consideration, over several years, the society, though its pride of ownership resisted the idea, felt that it was best in all interests that the books should remain where they are, and accordingly offered them to the University on terms permanently favourable to its members.

Growth of the Library.

The first catalogue of the library (1835) comprised 1,075 volumes and pamphlets. It grew very slowly, only 800 books being added in ten years, and it was not until 1858, when Thomas Windsor undertook to act as its honorary librarian, that there was considerable increase in the number of books, 10,000 volumes being added in the next six years. Windsor was an ophthalmic surgeon, but his heart was in books, and he obtained them for the society in large numbers from all over Europe, presenting many at his own expense. His object was to make the library as universal a storehouse of medical knowledge as was possible, and he carried this out so thoroughly by purchasing second-hand books of all dates, and European languages dead and alive, and in such quantities that the committee of the society eventually resolved that the money could be more profitably used for the purchase of current literature. The result was that Mr. Windsor withdrew his interest from the library and, it is sad to say, a handsome legacy for its maintenance from his will. He then collected for the American libraries, which readily took all he could send.

In addition to the 35,000 volumes belonging to the Medical Society the University has alone 20,000 of its own, acquired by purchase or by gift, for the Medical Society's library is not the first in the town which has been so transferred to the University. Thus the trustees of the Royal Infirmary and of the St. Mary's Hospitals found that their libraries, of about 7,000 volumes in size, occupied space which could be put to much practical use for charitable purposes, and as they were never used they presented them to the University. Both libraries contained many books which were duplicates of those in the library of the Medical Society and the University, and these have been disposed of in exchange for others, to the benefit of the common library. It adds greatly to facilities for study and research when all available books are collected in one large library, within one building, and under one authority, and are not scattered in smaller collections in different parts of the town under various owners.

Further contributions to such a central library were made by the Bolton and Macclesfield hospitals presenting their collections of books to it, and one would like to mention here the handsome legacy by the late Dr. Percy Cooper of close on 2,000 books, many of unusual medical interest and new to the society.

The library is very rich in complete sets of scientific medical periodicals, of British, German, French, and American publication, and in this line alone offers facilities for scientific research which are unequalled in any medical library in England, outside London. A new feature of it is a collection of all matters of historical interest in local medical life, biographical notices, portraits of local doctors, hospital reports, scientific journals, etc.

Some Treasures of the Collection.

In the space at my disposal I can give only a brief account of some of the books that belonged to the Manchester Medical Library. There were about a dozen incunabula—that is, books printed in the cradle age of the art, the fifteenth century, and all from Continental presses; the earliest book is of the date 1480 from an Italian press. Some of them are very fine examples of the earliest book-producer's work—ink as black, and paper as white, as on the day of publication. In all there are close on 600 books printed by foreign presses before 1600, 200 dating before 1550. And there are 150 copies of English printers' work before the date 1675, and another 100 before 1700.

Among the treasures are fine copies of the Aldine Press of Venice, which was established late in the fifteenth century, and of the Elzevir Press, which was publishing in various towns in Holland a century later. The earliest printed book in the collection is a large folio volume on a surgical subject which was printed by Nicolaus G. Ghirardengus on his first press at Venice in 1480. Only three copies are known to be in libraries—one in the very large collection of the Surgeon-General, Washington, one in the Royal Library at Berlin, and the other in the Medical Society's library. It is an Italian version of Guy de Chauliac's *Chirurgia magna*, which passed through many editions and translations, and became the textbook of surgical practice beyond the sixteenth century. He lived from 1300 to 1368 at Avignon, and was the most erudite surgeon of his time. His account of the Black Death clearly shows that our modern Oriental plague is identical with the disease that spread from Asia and Africa into Europe about 1348, and is reputed to have then caused a mortality of one-fourth of the population of the world.

A short manuscript written about Henry VII's reign on a medical subject, and very like notes of a lecture on urines, with small line illustrations, recently attracted the attention of a collector, who offered £150 for it. Some of the bindings of the early printed books are fine examples of a master binder's work.

There are a dozen books printed in the sixteenth century in London, the earliest date being 1548. A rare English book is the *Speculum Matricis or the Expert Midwives Handmaid*, by J. Wolveridge (London, 1671). Only two other copies are known, and these are in the libraries of the Royal College of Physicians of Edinburgh and the Royal College of Surgeons.

A very interesting volume in the library contains six, more or less complete, rare and curious tracts. Five of them
